Injury to alfalfa and red clover by the potato leafhopper, F. W. Poos and H. W. Johnson (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 325–331, figs. 2*).—In work at the Arlington (Va.) Experiment Farm the reduction in yield in cages caused by the potato leafhopper to alfalfa ranged from 13.9 to 27 percent during the years 1929, 1931, 1932, and 1933. Experimental data are presented

to show that the amount of injury which it causes to alfalfa and red clover is directly proportional to the numbers attacking these plants. In experiments conducted with vegetatively propagated lines of red clover to test the choice for oviposition by the potato leafhopper, 74.6 percent of the total (2,052) nymphs hatched from the foreign, more glabrous, Italian lines, while 25.4 percent hatched from a native rough-hairy Ohio line selected for vigor.

A leafhopper pest of clover and alfalfa, H. H. JEWETT (*Kentucky Sta. Circ. 44 (1936), pp. 7, figs. 3*).—A practical account is given of the potato leafhopper as an enemy of clover and alfalfa, studies of which by the author have been noted (E. S. R., 71, p. 815; 73, p. 809).

The Virginia creeper leaf-hopper, J. H. PEPPER and H. B. MILLS (*Montana Sta. Bul. 314 (1936), pp. 4, fig. 1*).—A brief practical account is given of the grape leafhopper, its distribution, seasonal history, and control. This leafhopper is said to have been increasing in importance during the past 10 yr. as an enemy of the Virginia creeper in Montana. A spray consisting of 1⅔ oz. of Black Leaf 40, 8 oz. of summer oil emulsion, and 5 gal. of water is said to have given the highest degree of control.

Laboratory method of comparing the toxicity of substances to San Jose scale, J. F. KAGY (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 393–397*).—A description is given of a method that has given good results in comparing the toxicity of various substances to San Jose scale. This method, which affords a means by which homogeneous results can be obtained and accurate comparisons of materials made without danger of erroneous conclusions being formulated, it is thought can be extended for usage in toxicity studies with other scale insects.

Comparative toxicities of methyl thiocyanate and hydrocyanic acid to the California red scale, F. H. LATHROP, H. L. CUPPLES, J. HILEY, and H. R. YUST (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 410–412, figs. 2*).—The studies reported have demonstrated that the vapor of methyl thiocyanate as a fumigant is remarkably toxic to all stages of the California red scale. "Molecule for molecule, it is equally as toxic as hydrocyanic acid. In selecting a fumigant for the fumigation of trees, however, other important factors must be taken into consideration. The fumigant should preferably be readily volatile, although it might be found possible to overcome some deficiency in respect to volatility, and it is a fundamental requirement that a dosage sufficient to kill the scale shall not cause excessive injury to the tree. In each of these respects methyl thiocyanate is probably inferior to hydrocyanic acid. It is much more difficult to volatilize, and small-scale tests on young citrus trees indicated that it is too injurious to the trees for successful fumigation. The studies of the effects upon the plant tissues are not definitely conclusive, however."

Anomis erosa Hubn. as an insect pest of cotton, J. T. CREIGHTON (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 279–282*).—A report is made of observations of the abutilon moth as a leaf defoliator of cotton during a period of 3 yr. in Florida. Numerous plants of the Malvaceae were found to be attacked, those subject to quite extensive damage by the larvae including flowering maple, okra, cotton-rose, roselle, Chinese mallow, cotton, swamp or rose mallow, bell pepper, and *Urena lobata*, *Abutilon avicenna*, and *Malva rotundifolia*.

The moth is known to occur in 17 States and the District of Columbia, from Massachusetts to Florida and westward to New Mexico, Texas, Oklahoma, and Kansas. Of its several parasitic enemies *Syntomosphyrum esurus* Riley, a parasite of the pupa, is one of the most common and efficient. The egg parasite *Trichogramma pretiosa* Riley aids materially in its control. Two species of Diptera, *Megoselia scalaris* L. and *Publiciphora* spp. have been

found to attack it. Several species of Hemiptera have been found preying upon the larvae and pupae.

Status of the tomato pin worm Gnorimoschema lycopersicella Busck in Pennsylvania, C. A. THOMAS (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 313–317*).—In continuation of earlier observations by the Pennsylvania Experiment Station (E. S. R., 69, p. 80), the tomato pinworm has been found present in greenhouses from Oxford, Chester County, on the west, to Chester, Delaware County, on the east, and from the north of Unionville, Chester County, on the north, south into northern Delaware. In the Chester County area it has been found feeding on four species of solanaceous plants, including the tomato, eggplant, potato, and horse nettle. Notes are given on its biology, natural enemies, and control measures. The apparent difficulty experienced by the insect in passing the winter outdoors and the fact that it will not feed on the common greenhouse flowering plants have led to the recommendation that growers in the Pennsylvania area either omit the fall crop of tomatoes and substitute flower crops, or that they leave the greenhouses open to the weather for some time between the end of the fall crop and the beginning of the spring crop in February. These methods are said to have been very effective where they have been tried, the first mentioned being apparently the more effective.

Observations on the life history of Platynota stultana Wlsm. on greenhouse rose, R. H. NELSON (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 306–312*).—The tortricid leaf roller *P. stultana*, a native of Mexico and California, was found on roses in a greenhouse at Alexandria, Va., in September 1933, when about 15 percent of 100,000 rose plants in the greenhouse were infested. This is said to have been the first discovery of the moth as a pest of greenhouse roses in the eastern United States. The procedure and methods for the life-history studies of this insect are described. The studies were made at approximately 70° F. The habits and appearance of the various stages are discussed. The mated females readily oviposit on glass slides when confined in wire screen cages, and complete and accurate oviposition records were therefore possible. This moth is apparently not parthenogenic, since unmated females either died without ovipositing or laid abnormally shaped eggs which did not hatch. The average number of eggs deposited per fertilized female was 293.6. The largest number of eggs laid in one day by one moth was 188. Average lengths of the various stages are as follows: Incubation period 9 days, larval period 31.1 days, pupal period 9 days, and from egg to adult 48.6 days. As calculated by Dyar's rule there are five instars. Three species of hymenopterous parasites, *Meteorus dimidiatus* (Cress.), *Angitia ferrugincipes* (Ashm.), and *Cremastus* sp., were reared from *Platynota* larvae collected on greenhouse roses.

The corn ear worm in southeastern Georgia, G. W. BARBER (*Georgia Sta. Bul. 192 (1936), pp. 18, figs. 8*).—This contribution briefly refers to the importance of the corn earworm, its food plants, damage to corn, damage by other insects following earworm attack, its several stages, seasonal history, natural limiting factors including cannibalism of larvae and other enemies, and methods by which injury to corn may be limited.

Cold-water treatment as a control for the sugar cane borer, E. K. BYNUM and A. I. BALZER (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 458, 459*).—The results of experiments conducted independently at two locations, one at Houma, La., and the other at Beaumont, Tex., definitely show that the immersion of sugarcane for 72 hr. in water at ordinary temperatures gives only a partial kill of the sugarcane borer. This treatment cannot be recommended for treating

infested sugarcane destined for borer-free territory. The mortality is high enough to give partial control, and the treatment might be advisable as a plantation practice under some conditions.

The wax moth and its control, W. WHITCOMB, JR. (*U. S. Dept. Agr. Circ. 386 (1936), pp. 14, figs. 5*).—An account is given of the economic importance and sources of loss caused by the wax moth, its history and distribution, life history, other moths causing damage to stored combs, and natural and artificial control.

Effect of procedure on performance of certain insecticides recommended for codling moth control, H. G. GUY, P. L. RICE, and L. A. STEARNS (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 378–383, fig. 1*).—In control work with the codling moth at the Delaware Experiment Station lead arsenate was found to be decidedly the most effective insecticide of those tested in protecting the fruit from attack. Calcium arsenate, zinc arsenate, Kalo, and Manganar were effective in the order named. Spray drift did not affect the relative efficiency of these insecticides when tested by the single-tree plat procedure. Although the spray deposit on the foliage of single-tree plats was adulterated by spray drift, the fruit was largely protected by the foliage from such adulteration. Single-tree plats have the advantage of covering a small area and provide replicates, therefore, less subject to pronounced environmental differences. Single-tree plats should be enlarged, however, by one or two trees to overcome the possibility of a poor set of fruit, and should be replicated a sufficient number of times to offset such a condition.

Codling moth experiments in New Jersey in 1935, B. F. DRIGGERS (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 369–378*).—In further work at the New Jersey Experiment Stations (E. S. R., 73, p. 76), 10 different combinations of nicotine were tested in comparison with lead arsenate-lime and lead arsenate-summer oil on three varieties of apples in the two-brooded codling moth area at Glassboro. Relative codling moth control and the effect of the materials on fruit and foliage were determined. Three spreaders to be used with tank-mixture bentonite-nicotine were tested. Summer oil plus nicotine was compared with nicotine tannate in the last two or three sprays following bentonite-nicotine, both as regards codling moth control and effect on residue at harvest. The amount of nicotine deposited and retained on the foliage by the different nicotine combinations was studied.

Based on clean fruit produced at harvest, a proprietary compound of bentonite and nicotine carrying a zinc sticker (Black Leaf 155B) gave the best control of codling moth, being superior to lead arsenate-lime and lead arsenate-summer oil. It was superior to lead arsenate-lime in preventing wormy fruit, but not as effective as lead arsenate-summer oil. However, severe foliage injury appeared late in the season on two varieties sprayed with Black Leaf 155B. A loose, oily, dust coating characteristic of the B formula appeared to give control of codling moth superior to tank-mixed bentonite-nicotine carrying double or triple the amount of nicotine on foliage. Tank-mixed bentonite and nicotine compared favorably with lead arsenate-lime and lead arsenate-oil in the production of clean fruit at harvest. It was superior to either lead arsenate schedule in cutting down stings, but was inferior to lead arsenate-oil in preventing larval entry. The tank-mixed bentonite-nicotine had the additional advantage of producing no fruit or foliage injury. Nicotine sulfate and summer oil was found superior to nicotine tannate as a spray to follow bentonite-nicotine both for worm control and residue removal. Aresket and dried skim milk were found to be equal to sulfo-ammonium soap as a spreader for tank-mixed bentonite-nicotine. Lime added to bentonite sulfur-nicotine in the second-brood sprays

aided in the removal of the residue, but greatly reduced the amount of nicotine on the foliage between sprays.

Laboratory tests with impregnated oil as codling moth larvicides, E. R. McGovran (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 417–420*).—In a study of the toxicity of available chemical compounds about 100 materials were mixed with a refined petroleum oil and tested in the laboratory on newly hatched codling moth larvae. Of these, nicotine sulfate, methyl salicylate, copper cyanide, copper oleate, alpha naphthylamine, and iodine were the most toxic at concentrations of 2 percent or less in the oil.

Chloropid populations on pasture grasses in Kansas, D. A. Wilbur and C. W. Sabrosky (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 384–389, figs. 6*).—With the view to obtaining information on the insect population of grasslands, their numerical abundance and seasonal distribution, relationship to the grasses on which they are found, and their relationship to neighboring crops, regular and standardized semiweekly collections were inaugurated and carried on by the Kansas Experiment Station throughout the entire growing seasons of 1933 and 1934. In the course of the study approximately 11,300 chloropid flies, representing 14 genera and 53 species, were collected, examined, and identified. The results are presented in 5 charts.

Toxic action of formaldehyde on the adult house fly (Musca domestica L.), J. C. Elmore and C. H. Richardson (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 426–433, fig. 1*).—In work with the housefly the effect of formaldehyde was determined by feeding individual flies small drops of solutions which contained known concentrations of formaldehyde or paraformaldehyde. The amount of toxic liquid imbibed was ascertained immediately after feeding from the gain in weight of the fly. The population from which the test insects were taken comprised flies weighing from 7 to 24 mg, with a mean weight of 15.6±0.1 mg.

"Formaldehyde causes a progressive paralysis of the nervous system from posterior to anterior. The median lethal dose of paraformaldehyde calculated as HCHO is estimated as 2.24 mg per gram of body weight; for commercial formaldehyde it is estimated as 1.54 mg HCHO/g. The greater toxicity of unneutralized commercial formaldehyde solutions as compared with paraformaldehyde solutions probably results from the greater concentration of unpolymerized formaldehyde in the former solutions. The greater repellence of the commercial formaldehyde solutions may also contribute to their lower median lethal dose.

"Formic acid solution (pH 2.4) was less repellent to houseflies than a 3-percent solution of unneutralized commercial formaldehyde of pH 3.5. Paraformaldehyde solution (3-percent HCHO) adjusted to pH 3.5 with formic acid was also less repellent than unneutralized commercial formaldehyde solution. A solution of commercial formaldehyde, neutralized with potassium hydroxide, was similar in repellent properties to paraformaldehyde solution of equivalent HCHO concentration. The addition of alkali to commercial formaldehyde solution causes rapid polymerization as well as acid neutralization. The greater repellence of unneutralized commercial formaldehyde solution is probably the result of the greater concentration of unpolymerized HCHO in such solutions."

Dusts for control of flies on cattle, E. N. Cory, H. G. Harns, and W. H. Anderson (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 331–335*).—Outdoor work with flies on cattle in 1933 and 1934 has shown that the results of dusting and spraying experiments should be calculated on the basis of the average performance of a standard material in order that the effect of climatological variables may be evaluated. Impregnated dusts are generally superior to mixed

dusts in the same series. Stabilization does not significantly increase the value of the dusts. Pyrethrum-impregnated dusts provide more protection per unit cost than do the derris-impregnated dusts, but the derris-impregnated dusts are the more toxic per unit. Impregnated dusts gave better protection than the spray. Pine oils add little to the efficiency of the impregnated dusts. They increase the initial toxicity rating of the materials, but lower their efficiency over a 3.5-hr. period.

Observations on the West Indian fruit fly at Key West in 1932–33, L. C. McAlister (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 440–445*).—A report is made of investigations of the hosts and the reaction to poison sprays of two species of West Indian fruitfly, *Anastrepha acidusa* Walk. and *A. suspensa* Loew, on the island of Key West, conducted in 1932–33. The results of ovipositing experiments under cage conditions indicated that the species *A. acidusa* may successfully attack 35 different kinds of fruit, and that *A. suspensa* may also attack many of the same fruits. The results of insecticide tests confirmed the superior merits of tartar emetic as a fruitfly bait spray.

Observations on Anastrepha pallens (Coq.) reared from wild fruits in the lower Rio Grande Valley of Texas during the spring of 1932, M. McPhail and N. O. Berry (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 405–410, figs. 2*).—An investigation of the fruit fly *A.* (*Pseudodacus*) *pallens* undertaken in the spring of 1932 with a view to determining its possible economic importance in the lower Rio Grande Valley of Texas, where it was first collected in 1914, is reported upon. It has been found to breed in the small fruit of a bushy shrub, *Bumelia spiniflora*, found growing on uncultivated land. Vegetables and citrus appear to be free from its attack, even attempts to force oviposition in these crops having failed.

Certain insect vectors of Aplanobacter stewarti, F. W. Poos and C. Elliott (*Jour. Agr. Res. [U. S.], 52 (1936), No. 8, pp. 585–608, figs. 13*).—Hibernating adults of the corn flea beetle were found by the authors to harbor *A. stewarti*, the cause of bacterial wilt of corn, in a virulent condition in their bodies, it having been detected in 19 percent of the 175 beetles examined during April 1934. Young corn plants are inoculated with bacterial wilt in the spring by the feeding of these beetles, and this appears to be the chief source of early infection each year. The finding of earlier workers was confirmed in that bacterial wilt of corn is not transmitted through the soil. Direct transmission from infected to healthy corn plants was effected by means of the corn flea beetle, *Chaetocnema denticulata*, and the southern corn rootworm. Tests with 13 other species of insects yielded only negative results. A total of 7,338 insects, representing 40 species in 33 genera, collected on or near corn infected with bacterial wilt, during the corn-growing season in 1934, were tested for the presence of *A. stewarti*, and 8 species yielded this organism. A total of 3,977 isolations were made, 1,464 of which were suspected of containing *A. stewarti* and were tested by inoculation on corn, 953 yielding positive results. From six species, not including the *Chaetocnema* spp., *A. stewarti* was obtained in only a single instance and additional work is necessary to determine the importance of these species as vectors of this organism. Collections of adults of the corn flea beetle from 12 different host plants and from 29 different localities yielded *A. stewarti* in from 0 to 75 percent of the individuals in each collection.

Notes on biology and control of the Asiatic garden beetle, H. C. Hallock (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 348–356, fig. 1*).—This contribution on *Autoserica castanea* Arr. supplements work previously noted (E. S. R., 68, p. 791; 71, p. 353).

Value of lime and aluminum sulfate as a repellent spray for Japanese beetle, F. W. METZGER and J. W. LIPP (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 343–347, fig. 1*).—In control work with the Japanese beetle the application of 20 lb. of hydrated lime and 3 lb. of aluminum sulfate to 100 gal. of water protected the foliage of Yellow Transparent and Red Astrachan apples from the attack, three applications being necessary in an area very heavily infested by the beetle. Early-ripening fruit cannot be protected by this spray unless careful orchard sanitation is practiced and the crop ripens uniformly. Protection from beetle attack is afforded to peach foliage and fruit by the use of this combination, but after July 1 it cannot be applied with safety on early-ripening varieties because of the objectionable residue.

Beetle injury on asparagus brush is materially reduced by 3 applications of 20 lb. of hydrated lime, 6 lb. of aluminum sulfate, and 0.5 lb. of sodium lauryl sulfate to 100 gal. of water. The foliage of cultivated blueberries and rhubarb can be protected by 2 or 3 applications of lime and aluminum sulfate at the same concentration as that employed on peach and apple.

Value of improvements in Japanese beetle traps and bait as measured by the numbers of beetles caught, F. W. METZGER (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 449–454, fig. 1*).—It is pointed out that work conducted over a period of 10 yr. with Japanese beetle traps has resulted in a considerable improvement of such devices with respect to attracting beetles and to capturing insects thus attracted. The data indicate that, in an equal infestation, the 1934 trap is probably capable of capturing 55 times as many beetles as the device used in 1925. In lightly infested areas, traps capture a higher percentage of the beetles which are attracted than in regions where the beetle is present in great abundance. Improvements in bait have not resulted in a trap which will attract all the beetles in the immediate vicinity, nor have the improvements in the trap resulted in one that will capture all the beetles which are attracted.

The effectiveness of various arsenicals in destroying larvae of the Japanese beetle in Sassafras sandy loam, W. E. FLEMING and F. E. BAKER (*Jour. Agr. Res. [U. S.], 52 (1936), No. 7, pp. 493–503, fig. 1*).—In continuation of studies of insecticide control of the Japanese beetle larvae (E. S. R., 71, p. 227; 72, pp. 80, 81, 230; 74, p. 237), the relative effectiveness of the inorganic arsenates and arsenic trioxide as stomach poison insecticides for destruction of the larvae of the Japanese beetle in the soil was determined under controlled conditions immediately after application and at intervals up to 60 mo., more than 18,000 tests being made.

The period of time in the soil was the most important factor associated with the effectiveness of the arsenates, but other factors were more important in modifying the insecticidal action of arsenic trioxide. Acid lead arsenate appeared to be the most dependable arsenical for killing larvae; zinc arsenate and ferric arsenate were almost as consistent. Basic lead arsenate was of no value. Magnesium arsenate and dicalcium arsenate decreased in effectiveness more rapidly than acid lead arsenate, but no significant difference in the rate of change was noted with the other materials. The decrease in effectiveness in the field is attributed to the slow conversion of the arsenic into a form, possibly a complex basic salt, that is not toxic to the insect, as well as to loss by leaching.

Notes on life history, habits, and distribution of Heteroderes laurentii Guér., K. L. COCKERHAM and O. T. DEEN (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 288–296, figs. 11*).—Observations on the Gulf wireworm, first recognized as an economic pest in the United States in Baldwin County, Ala., in 1927, have shown the species to complete its life cycle in a single year. The contribution

reports upon its present known distribution, seasonal peaks of egg deposition and pupation, the crops attacked, and habits of larvae and adults. Notes on flight, hibernation, field populations, and natural enemies are included.

The flour beetles of the genus Tribolium, N. E. Good (*U. S. Dept. Agr., Tech. Bul. 498 (1936), pp. 58, figs. 22*).—The first part of this contribution consists of a partial revision of the genus *Tribolium*, represented by seven species, namely, *T. castaneum* Herbst, *T. confusum* J. du Val (officially known as the confused flour beetle), *T. madens* Charp., *T. destructor* Uyttenb., *T. gebieni* Uyttenb., *T. indicum* Blair, and *T.* (*Leanum*) *myrmecophilum* Lea. A key is given for their identification together with synonymies and descriptions of the first four, or economically important, species as well as of the genus.

The confused flour beetle and *T. castaneum* are by far the most abundant and destructive beetles infesting flours and other prepared cereal products. A large part of the bulletin is devoted to the life history of *T. castaneum*, shown to be the correct name of *T. ferrugineum* Fab., officially known as the rust-red flour beetle. The duration of the different stages and of the different larval instars at room conditions, 25°, 27°, and 30° C., are given for *T. castaneum* and for the confused flour beetle. The incubation period of the eggs at 27° averaged 5.2 days for *T. castaneum* and 6.8 for the confused flour beetle. The number of larval instars ranges from 5 to 11 and the larval period from 22 to over 100 days, depending on environmental conditions and individual variation. Larval head capsule widths are given. The average pupal periods at 27° were 7.1 days for *T. castaneum* and 7.9 days for the confused flour beetle. Adults lived as long as 3 yr. 271 days. The longest oviposition periods recorded were 432 days for the confused flour beetle and 308 days for *T. castaneum*. The greatest number of viable eggs laid by a single female was 976 for the confused flour beetle and 956 for *T. castaneum*.

A disease caused by a coccidian, *Adelina* sp., kills large numbers of *Tribolium*. The mite *Acarophenax tribolii* New. and Duv. is the most common parasite, while the straw itch mite and the bethylids *Rhabdepyris zeae* Turner and Waterston and *Sclerodermus immigrans* Brid. are also recorded as parasites. The hemipteran *Xylocoris cursitans* Fall. and adults of the cadelle are recorded as predators. Control methods include fumigation with hydrocyanic acid gas or chloropicrin, and the use of heat.

A list of 108 references to the literature is included.

Preliminary report of trap-log studies on elm bark beetles, C. H. Martin (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 297–306, fig. 1*).—In studies of the dark native elm bark beetle *Hylurgopinus rufipes* Eichoff and the European elm bark beetle *Scolytus multistriatus* Marsham, the largest number of the former were found to come to early spring-cut logs while the largest number of the latter came to early August-cut logs.

"For both species of beetles there was a correlation between a low degree of infestation and noninfested logs. Logs in deep shade attracted the most *Hylurgopinus* while those in brighter locations attracted the most *Scolytus;* logs in too bright a location were not as attractive to *Scolytus* as those that were semishaded. In the experiment reported, vertical logs attracted only half as many *Scolytus* as the horizontal. Individual logs apparently remained attractive to *Hylurgopinus* and *Scolytus* for a longer period than a whole cutting. Under the proper conditions isolated logs seemed to be about as attractive to *Hylurgopinus* as groups of racked logs. Logs in clearings under lath shelters were not attractive to either *Hylurgopinus* or *Scolytus*. Suspended logs attracted many *Magdalis*. Paraffin logs did not increase beetle infestation. There did not seem to be any correlation between the moisture content of the

phloem of logs and *Hylurgopinus* and *Scolytus* infestations. No girdled trees were infested. A difference of 3.5 to 8.5 in. in the diameter of a log did not influence either *Hylurgopinus* or *Scolytus* infestation."

Strawberry root-weevil control in Oregon, D. C. MOTE (*Oregon Sta. Circ. 115 (1936), pp. 12, figs. 10*).—This is a practical account of the activity of the strawberry root weevils and means of their control, based upon the investigations of Wilcox et al., previously noted (E. S. R., 75, p. 232).

Further developments concerning wax production by the honeybee colony.—I, A study of the production of wax scales and comb building, C. M. GWIN (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 318–321, figs. 3*).—In an experiment conducted, colonies of bees fed either honey or sugar sirup produced wax without being fed pollen. When fed sugar sirup and water in a temperature-controlled compartment, a colony of bees was kept producing wax for a period of 6 mo. When used for wax production, bees persisted longer when fed sugar sirup than when fed honey, other factors remaining constant. It was possible to rear young bees under these controlled conditions provided they were supplied sufficient pollen, honey or sirup, and water.

Spray and dust poisoning of honeybees in New Jersey, R. S. FILMER (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 322–324*).—Observations by the New Jersey Experiment Stations have shown the increase in arsenical poisoning of honeybees in that State during recent years to be due to (1) increased use of arsenical dusts to combat insect pests, (2) the use of sweetclover as a permanent cover crop in orchards where heavy spraying for codling moth or where special Japanese beetle sprays are applied, (3) an unusual apple scab situation during the blooming period, which resulted in the early application of the petal-fall spray, and (4) unusually dry weather during the summer of 1935, which resulted in the failure of the clover crop and which provided ideal conditions for the retention of the dust on the plants for prolonged periods.

Effectiveness of sodium fluoride, arsenic trioxide, and thiodiphenylamine as food poisons for the firebrat, Thermobia domestica (Packard), B. T. SNIPES, R. E. HUTCHINS, and J. A. ADAMS (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 421–426, fig. 1*).—In control work "firebrats reared and kept at 34.5° C. and about 70 percent relative humidity were confined singly with access to their preferred food mixed with various concentrations of three poisons. Care was taken that the insects were not compelled to remain in contact with the bait. In addition to the controls, none of which died, 100 individuals were tested with each concentration for periods of 1 week. With thiodiphenylamine, at concentrations up to 20 percent, only a few insects died in 1 week. With arsenic trioxide, 4, 12, and 20 percent, about two-thirds of the insects died. With sodium fluoride, 4, 8, and 12 percent, about nine-tenths of the insects died. Preliminary tests indicated that both contact effects and repellence by poisons are significant in the effectiveness of these mixtures. A bait is recommended in which 7 percent of the weight is sodium fluoride."

Mass liberation of an oriental fruit moth parasite, D. M. DANIEL (*Jour. Econ. Ent., 29 (1936), No. 2, pp. 459–461, fig. 1.*).—The results of liberations of the parasite *Macrocentrus ancylivorus* Roh. by the New York State Experiment Station in a solid block of some nine thousand 10- to 20-year-old peach trees largely of the Elberta variety, growing on 72 acres during the years 1932 and 1933, are reported. The infestation of this orchard by the oriental fruit moth had increased to a point where about half the fruit was injured in 1932. On July 14 of that year a colony of 200 female parasites was liberated in the orchard, and at the harvest period 48.34 percent of the 5,625,000 fruits was found infested by the oriental fruit moth. The following year, 1933, 12,000

female parasites were liberated during the 2-mo. period, June 30 to August 31, and at harvest time 15.96 percent of the estimated 4,680,000 fruits produced was found infested. This was a reduction of 72 percent. It is pointed out that three nearby orchards which received liberations in 1932 only, showed infestations practically the same in 1933 as in 1932. The experiment is said to have come to an abrupt end following the subzero weather of the winter of 1933–34, when practically all the trees in the block were killed outright or severely injured. It cannot now be repeated since practically every peach orchard in the State at the present time contains this parasite either through liberation or spread from colonized areas, and the fruit moth population has fallen too low for mass liberations to be of benefit.

Chrysis shanghaiensis Smith, a parasite of the oriental moth, D. E. PARKER (*Jour. Agr. Res. [U. S.], 52 (1936), No. 6, pp. 449–458, figs. 5*).—The results of 2 years' study of the life history and habits of *C. shanghaiensis*, introduced from Japan to attack the oriental moth, are reported upon. The adult female, which is very active and capable of strong flight, attacks the larvae of the moth by chewing a hole in the cocoon, depositing an egg in it external to the larvae, and then sealing the hole. The egg of this parasite hatches in about 4 days, the larvae complete the first stadium in an average of 4 days, and the second, third, and fourth stadia in an average of 3 days each. The last-instar larva encloses itself in a golden silken cocoon, where it remains throughout the winter. The larva pupates during the latter part of June, and the adults emerge late in July and in the first part of August. Uncompleted experiments on the interrelations of *C. shanghaiensis* and *Chaetexorista javana* indicated that some competition existed when both species attacked the same host larva.

The low temperatures of the winter of 1933–34 proved too severe for the *Chrysis* larvae held at the laboratory, and it was considered that such low temperatures would limit the survival of the parasite in the vicinity of Boston where the oriental fruit moth is established.

The cyclamen mite (Tarsonemus pallidus) and its control on field strawberries, L. M. SMITH and E. V. GOLDSMITH (*Hilgardia [California Sta.], 10 (1936), No. 3, pp. 53–94, figs. 8*).—The cyclamen mite (incorrectly known as the strawberry mite, *T. fragariae* Zimm.), which first appeared on strawberries in 1892 and has been reported in 10 European countries and 27 States in this country, has become the most important economically of the animal pests attacking field and greenhouse strawberries in California. It causes severe injury to the Nick Ohmer strawberries in central California, in which area the Marshall variety is resistant. The Klondike variety is not seriously affected in southern California.

"The majority of adult mites are females, which lay two or three eggs a day. The immature stages are completed in about 13 days, hence a very rapid increase in population is possible. The mites live in the folded leaves in the center of the crown of the plant. Their feeding punctures cause severe distortion and dwarfing of the leaves. Only adult females survive the winter. They hibernate in the crowns between the bases of the petioles. They emerge from hibernation about the latter part of February.

"No satisfactory method of controlling the mites on established plants has been found. However, they can be eradicated from planting stock and the field subsequently kept free from mites. A complete kill of mites on planting stock can be obtained by immersing the plants in water at 110° F. for 30 min. or by treating the plants with saturated air at 110° for 1 hr. Of these

two methods, the vapor treatment is superior to the immersion method. For treatment, plants must be removed from shipping boxes and loosened if tied in bundles. They should be placed loosely in screen or slat trays or boxes and stacked to allow a maximum of penetration of either the hot water or vapor. After treatment the plants should be cooled and dried before repacking. Precautions should be taken to prevent excessive drying. If plants are repacked while wet saprophytic fungi may kill a large percentage of them. Varieties show varying sensitivity to heat treatments. Klondike and Nick Ohmer are relatively resistant, while Dorsett is more easily injured. In either method the temperature must be accurately held at 110° and should not vary more than 1°. The heating medium (water or vapor) must be thoroughly agitated to insure uniform exposure of all plants to the desired temperature. Planting should follow treating as soon as possible. Plants should be set in clean soil as far from old infested fields as possible, preferably 500 yd. or more."

ANIMAL PRODUCTION

The American Society of Animal Production: Record of proceedings of the twenty-eighth annual meeting, November 29 and 30, 1935 (*Amer. Soc. Anim. Prod. Proc., 1935, pp. 317, figs. 8*).—This is the report of the annual meeting held at Chicago, November 29 and 30, 1935 (E. S. R., 73, p. 824). The following papers were presented in the dairy cattle, beef cattle, swine, horse, sheep and lambs, nutrition, and meats sections:

Animal Husbandry's Responsibility in Land Use Planning, by H. H. Kildee (pp. 9–16); The Relation of Population Trends to Commercial Agriculture, Especially to Production of Animal Products, by O. E. Baker (pp. 16–30); Changes Which Will Come in Animal Husbandry of the Western States if Planned Utilization of Land Becomes a Reality, by J. A. Hill (pp. 30–37); Changes in Corn Belt Husbandry and Types of Problems Involved, by W. C. Coffey (pp. 38–43); Prospective Changes in Animal Husbandry in the Eastern States, by H. L. Garrigus (pp. 43, 44); Adjustments Which a Land Utilization Program May Bring in Dairy Production, by E. L. Anthony (pp. 45–49); Correction Factors and Germ Plasm in Dairy Cattle Breeding, by W. L. Gaines (pp. 50–53); Variations in Mammary-gland Development in Dairy Calves, by W. W. Swett and C. A. Matthews (pp. 54–59); Some Influences That May Change the Lactose Content of Milk, by W. E. Petersen (pp. 59–63); Shrimp Meal for Milk Production, by R. H. Lush (pp. 63–66); Length of Service Period in Relation to Productive and Reproductive Efficiency in Dairy Cows, by A. B. Chapman and L. E. Casida (pp. 66–70); Adjustments Which a Land Utilization Program May Bring in Beef Production, by R. Beresford (pp. 71–75); The Consumption of Reed Canary and Brome Grasses by Grazing Steers, by W. P. Garrigus and H. P. Rusk (pp. 75–82); Creep Feeding Range Calves.—Final Report, by E. B. Powell (pp. 83, 84); Florida Range Cattle Problems, by A. L. Shealy (pp. 85–88); The Corn Plant for Wintering Stock Calves, by R. R. Thalman and H. J. Gramlich (pp. 89–93); Roughages as a Factor in the Fattening Ration for Steer Calves, by W. L. Blizzard (p. 93); The Preparation of Feeds for Cattle.—II, A Study of the Chemical and Physical Composition of the Residual Ingesta in the Rumen at the End of a Twenty-four Hour Period, by C. H. Kick and P. Gerlaugh (pp. 93–98); Adjustment of Pork Production to Land Planning Program, by L. A. Weaver (pp. 98–100); The Value of Garbage in the Ration of Growing and Fattening Pigs,

by J. C. Miller (pp. 101–104); Expeller Processed Soybean Oil Meal Compared With Other Protein Supplements, by E. F. Ferrin (pp. 104–106); The Influence of the Protein Content of the Ration on the Growth and Fattening of Hogs Fed at a Moderately Restricted Level, by N. R. Ellis and O. G. Hankins (pp. 107–111); A Study of Ham Composition With Special Reference to Type of Hog, by O. G. Hankins and N. R. Ellis (pp. 111–116); A Method of Comparing Growthiness in Pigs Weighed At Different Ages and Subjected to Different Treatments, by J. H. Bywaters and O. S. Willham (pp. 116–119); The Relative Accuracy of One-day and Three-day Weights of Pigs, by F. Hale and C. B. Godbey (pp. 119–122); Readjustment of Horse Production to the Diversified Farm, by J. G. Fuller (pp. 122–126); Economical Pastures for Horses, by R. S. Hudson (pp. 127–129); Indiana Spring Stallion Shows, by P. T. Brown (pp. 129–131); Fundamental Horse Economics, by T. A. Ewing (pp. 131–134); Our Mule Supply, by J. O. Williams (pp. 135–137); Changes Which a Planned Utilization of Land May Bring in Sheep Production, by E. L. Potter (pp. 137–140); The Relation of Tip on Finewool Fleeces to Topmaking Qualities, by J. F. Wilson (pp. 141–144); Cross Sectional Variability of Wool Fibers, by J. I. Hardy (pp. 144–146); The Growth of Skin Area in Sheep, by R. H. Burns (pp. 146–151); Effect of Pregnancy and Early Lactation on Wool and Mohair Production, by J. M. Jones, B. L. Warwick, and S. P. Davis (pp. 151–153); Estrus and Ovulation in the Ewe.—A Preliminary Report, by C. E. Terrill (pp. 153–158); Supplements on the Winter Range for Breeding Ewes, by D. W. Chittenden, W. F. Dickson, and F. Barnum (pp. 159–161); The Efficiency of Feed Utilization in Lambs, by R. W. Phillips (pp. 161–163); The Influence of Fluorine on the Basal Metabolic Rate of the White Rat Fed Desiccated Thyroid, by P. H. Phillips (pp. 240, 241); The Balancing of Rations With Respect to Protein, by H. H. Mitchell and T. S. Hamilton (pp. 241–252); The Requirements of Phosphorus in the Ration of Growing Pigs, by C. E. Aubel and J. S. Hughes (pp. 253–258); Storing Chopped Alfalfa Hay in Ventilated Containers, by B. H. Roche (pp. 259–262); The Significance of Fat in the Rations of Farm Animals, by L. A. Maynard (pp. 263–267); Vitamin A in the Nutrition of Cattle and Swine, by E. B. Hart (pp. 267–274); Preserving Farm Dressed Beef in Freezer Storage, by K. F. Warner (pp. 275–278); Color Standard for Beef, by D. L. Mackintosh (pp. 279–281); Some Factors Related to Color of Meat, by D. L. Mackintosh and J. L. Hall (pp. 281–286); The Effect of Ingested Menhaden and Coconut Oils Upon the Firmness of Beef Fat, by F. J. Beard, J. A. Schulz, and C. C. Culbertson (pp. 286–290); and The Rate and Amount of Salt Absorption in Pork Curing, by P. T. Ziegler and R. C. Miller (pp. 291–293).

[Animal production and poultry studies in the Southern States] (*Assoc. South. Agr. Workers Proc., 36 (1935), pp. 483–504, 592–600*).—The following papers were presented before the animal production and poultry divisions at the thirty-sixth annual convention of the Association of Southern Agricultural Workers held at Atlanta, Ga., January 30 to February 1, 1935: A Comparison of Rations for Fattening Steer Calves, by W. L. Blizzard (pp. 485, 486); The Influence of Age on Cost of Finishing Cattle for Market, by R. H. Means (pp. 487, 488); Herd Improvement Investigations in Florida, by B. Knapp, Jr. (pp. 488, 489); The Fluctuation of Pig Weights, by F. Hale and C. B. Godbey (pp. 489–491); Influence of Individuality on Feed Consumption of Inbred and Outbred Pigs, by W. A. Craft (pp. 491, 492); Winter Forages for Fattening Hogs, by E. G. Godbey (p. 492); The Effect on Quality of Pork When Corn Treated With Paradichlorobenzene Is Fed to Hogs, by W. W. Henley (pp. 493, 494); Beef Production in South Florida, by W. F. Ward (pp. 494,

495); Production of Cattle Feed and Utilization of Stable Manures in Crop Rotation for Sugar Cane Production, by W. R. Dodson (p. 496); Summary of Market Trends of Livestock, by J. H. Noble (pp. 497, 498); The Effect of the Length of Time in Brine on the Salt Content of Hams, by J. C. Grimes, W. E. Sewell, and G. J. Cottier (p. 498); The Report on the Study of Cured Meat Storage, by J. B. Francioni, Jr. (p. 499); Comparative Study of Quality of Meat of Native versus Grade Hereford Yearlings, by J. E. Foster (pp. 500–502); What is Flushing? by L. E. Hawkins and A. E. Darlow (pp. 502, 503); The Effect of Drench Upon the Gains and Parasites of Lambs, by M. G. Snell (pp. 503, 504); The Supplementary Value of Peanuts to the Laying Ration, by D. F. King and G. J. Cottier (pp. 502, 503); Controlling Mortality in Laying Flocks, by E. F. Stanton (pp. 594, 595); The Influence of Treatments for Internal Parasites Upon Egg Production and the Relative Efficiency of Treatment, by W. L. Bleecker and R. M. Smith (p. 595); Economic Aspects of Chick Sexing, by H. L. Shrader (pp. 595, 596); Breeding as a Factor in the Control of Blindness and Paralysis, by C. W. Upp (pp. 596, 597); Some Chick Starting Rations, by C. L. Morgan and D. F. Sowell (pp. 597, 598); and Confinement versus Range Rearing of Chicks, by N. R. Mehrhof (pp. 598, 599).

[Investigations with livestock in Hawaii], L. A. HENKE (*Hawaii Sta., Anim. Husb. Div. Prog. Notes No. 14 (1936), pp. 15–18*).—Tests with livestock produced information on the value of bananas for fattening swine, the value of cassava meal, sweetpotatoes, and pineapple bran-molasses mixtures for fattening swine, pineapple bran as a feed for mules, and fattening beef steers on feeds produced in Hawaii.

[Investigations with livestock in Massachusetts] (*Massachusetts Sta. Bul. 327 (1936), pp. 19, 73, 74*).—Information was obtained on variations in efficiency of feed utilization in lambs, and the relation of birth weight to growth rate in lambs, both by R. W. Phillips.

In poultry tests, results were obtained on breeding poultry for egg production, by F. A. Hays and R. Sanborn; rate of feathering in Rhode Island Reds, and breeding for low mortality, both by Hays; and breeding for high and low resistance to fowl paralysis, by Hays, C. S. Gibbs, W. C. Sanctuary, and J. H Vondell.

[Investigations with livestock in New Hampshire] (*New Hampshire Sta Bul. 289 (1936), pp. 5, 6*).—Results are noted on the nutrition of the horse, pig, and goat, by E. G. Ritzman and F. G. Benedict; and breeding investigations with sheep, by Ritzman.

[Livestock investigations by the North Dakota Station] (*North Dakota Sta. Bul. 286 (1935), pp. 13–23, 77–79, figs. 2*).—Data obtained in tests with steers are reported on Trebi v. common barley, silage from mature v. immature corn, linseed meal v. safflower oil meal, effect of linseed meal in the fattening rations, effect of an increased amount of ground barley and less alfalfa and silage, shortening the feeding period, corn silage v. finely chopped corn fodder, and a comparison of emmer fed alone and in combination with barley to fattening steers, all by F. W. Christensen; a comparison of blighted barley of the 1933 crop with bright barley of the 1932 crop in fattening steers, by E. J. Thompson and V. T. Sander; a study of the influence of intensity and rotation of grazing on the character of the range and the quality and palatability of the beef produced, by P. F. Trowbridge, T. H. Hopper, Thompson, A. Severson, D. Berrigan, and J. T. Sarvis; and the influence of cooking and canning on the antineuritic and antipellagric vitamins in meat, by Christensen, E. Lebsky, and Hopper.

The swine tests included self-feeding compared with limited feeding, and a comparison of Trebi and Manchuria barley when fed to pigs, both by Severson.

Under sheep tests, preliminary feeding trials with emergency feeds were conducted, by Christensen; and a study of the inheritability of wool by market grades, by D. J. Griswold and Thompson.

The rate of growth of draft colts was determined by M. J. Kirk.

The poultry tests included farm flock demonstration in management and cost, and temperature studies in the artificial incubation of turkey eggs, both by G. P. Goodearl; barley v. corn in the ration for laying hens, cost of wintering turkey breeding stock, and feed costs of growing turkey poults, all by O. A. Barton; and rape v. alfalfa pasture for growing turkeys, and calcium supplements in the ration for turkey poults, both by Barton and F. E. Moore.

[**Livestock investigations by the Wisconsin Station**] (*Wisconsin Sta. Bul. 435 (1936), pp. 30–44, 52–54, figs. 3*).—Data obtained in tests with livestock are reported on the effect of the method of preparing soybean oil meal on its value as a protein supplement in pig rations, by G. Bohstedt, J. M. Fargo, and J. W. Hayward; the value of animal proteins for pigs on rape pasture, and cheese meal made from cheese trimmings as a supplement in hog rations, both by Bohstedt and Fargo; need of large quantities of skim milk, whey, and tankage for growing and pregnant gilts, by Fargo; the desirability of uniform grinding when barley is to be hand-fed to pigs, by Bohstedt, Fargo, B. H. Roche, F. W. Duffee, and H. D. Bruhn; the effectiveness of various types of soil for preventing anemia in suckling pigs, by Fargo; and the necessity of zinc in animal nutrition, by F. Stirn, E. L. Hove, C. A. Elvehjem, and E. B. Hart.

Investigations with poultry resulted in data on a comparison of the rates of growth and feed costs of capons and cockerels, by J. G. Halpin and G. E. Annin; the effect of sterilizing the ration with steam for 30 min. on the normal growth of chicks, by Halpin, C. E. Holmes, C. A. Herrick, and G. L. Ott; the availability of some calcium combinations to poultry, by H. J. Deobald, Halpin, Elvehjem, and Hart; the availability of iron and copper in a practical poultry ration for healthy laying hens, by M. Schultze, Elvehjem, Hart, and Halpin; the value of cheese meal, a byproduct from cheese trimmings, in the poultry ration, by Halpin and Holmes; properly prepared soybean oil meal for replacing part of the animal protein in poultry rations, by Halpin, Holmes, and Hayward; the effects of fluorine in the diet, by P. H. Phillips and Hart; and the distribution of fluorine in the tissues of laying hens, by Phillips, K. S. Haman, and Halpin.

A review of the experimental work with phosphate in Montana, 1928–1935: Phosphorus for animals, J. R. Green (*Montana Sta. Circ. 148 (1936), pp. 11–16, fig. 1*).—A series of tests indicated that more phosphorus was assimilated by cattle fed monocalcium phosphate than by those fed bone meal and that it was the cheaper phosphorus supplement. The appetite of herds of cattle, and of individuals in the herds, for monocalcium-salt mixtures varied with the season, with age and condition of the cattle, and with the feeding and management. Some herds would consume a mixture of equal parts of these salts, while others required a smaller proportion of monocalcium phosphate. Mixtures that had been wet and dried were less palatable than fresh mixtures. Broad shallow troughs were preferable to deep narrow troughs for feeding the mixtures. The wild hays and grasses were most likely to be deficient in phosphorus.

Colorado fattening rations for cattle, H. B. Osland, E. J. Maynard, and G. E. Morton (*Colorado Sta. Bul. 422 (1936), pp. 120, figs. 28*).—Results are reported of beef cattle feeding experiments carried on to determine the feeding

values for calves and 2- and 3-year-old steers of concentrates such as corn, barley, and wheat; various beet byproducts, including wet, dried, and pressed molasses beet pulp, beet molasses, and beet tops in comparison with corn, barley, cull potatoes, and corn silage; carbonaceous roughages, such as corn silage, corn and soybean silage, corn fodder, sunflower silage, cull potatoes, and potato silage; and protein concentrates, including cottonseed cake, linseed cake, and flaxseed. Other experiments on which reports were presented were concerned with comparisons of steers with open heifers, influence of age and weight, market grades, and comparative methods of marketing steers by truck and rail.

The comparative values of eight protein supplements in stock cattle winter rations, C. W. McCAMPBELL and L. C. AICHER (*Kansas Sta., Fort Hays Substa., Beef Cattle Invest., 1935–36, pp. 4*).—In this experiment 8 lots of 10 calves each were fed the same amounts of early sumac cane silage daily for 150 days. In addition the respective lots received 1 lb. per head per day of the following protein supplements: Cottonseed meal, linseed meal, soybean oil meal, peanut oil meal, corn gluten meal, tankage, wheat bran (3 lb.), and alfalfa hay (4 lb.). The average daily gains in the respective lots were 1.3, 1.2, 1.2, 1.2, 1.2, 1.1, 1.5, and 1.4 lb. All supplements were readily eaten, and the weight gains in all lots were satisfactory. As the gains in lots 7 and 8 were significantly greater than those in the first six lots, 3 lb. of wheat bran and 4 lb. of alfalfa were worth more under the conditions of this test than 1 lb. of any of the other supplements.

Vitamin A deficiency, a cause of lameness and death among swine, E. H. HOSTETLER, J. E. FOSTER, and J. O. HALVERSON (*North Carolina Sta. Tech. Bul. 52 (1935), pp. 31, figs. 14*).—Experiments were carried on in 1929, 1930, and 1931 with 7, 4, and 6 pigs, respectively, on a basal ration of white corn, fish meal, and minerals which had produced characteristic symptoms in previous experiments due to a deficiency of vitamin A. Supplementing the basal ration by the substitution of yellow corn for white corn or 5% percent of alfalfa meal added to the ration or 1 oz. of cod-liver oil per day corrected the deficiency. Nearly all of the pigs exhibiting the deficiencies were cured when the vitamin A carriers were added to the basal ration. Confirmatory results were obtained in similar experiments with rats.

Determinations of the vitamin A content of the livers of the pigs and the rats showed that those on the basal ration were deficient in vitamin A, whereas the livers of pigs and rats receiving the supplements contained vitamin A. It was proved that vitamins D, B, and G were not factors in causing the difficulties since the pigs were exposed to direct sunlight and the ash and calcium contents of the bones were normal. Supplements of vitamins B and G to rat rations causing the deficiencies showed no improvement.

National poultry improvement plan (*U. S. Dept. Agr., Bur. Anim. Indus., Anim. Husb. Div., A. H. D. No. 14 (1935), pp. 13*).—This publication describes the national poultry improvement plan developed by the Department, the primary purpose of which is to identify, authoritatively, poultry breeding stock, hatching eggs, and chicks with respect to quality by describing them in terms uniformly accepted in all parts of the country.

The feasibility of sex segregation in day-old chicks, M. A. JULL (*Poultry Sci., 13 (1934), No. 4, pp. 250–254, figs. 4*).—A tabulation of the success in sexing day-old chicks by four investigators on the staff of the U. S. D. A. Animal Husbandry Experiment Station, Beltsville, Md., with an accuracy of about 90 percent, is reported. Descriptions are given of differences in the copulatory organs as used in determining the sex of young chicks.

Sexing baby chicks, C. S. GIBBS (*Poultry Sci., 13 (1934), No. 4, pp. 208–211*).—Directions for sexing baby chicks at hatching.

Feed consumption and growth standards, F. P. JEFFREY (*New Jersey Stas. Hints to Poultrymen, 23 (1936), No. 3, pp. 1*).—Feed consumption and growth standards of White Leghorns and Barred Plymouth Rock chickens and Bronze and White Holland Turkeys from birth to 24 weeks of age, based on records of several thousand normal birds hatched from February to May, are presented.

The influence of certain protein levels on the growth of pullets, R. S. DEARSTYNE, C. O. BOLLINGER, G. K. JONES, and H. P. BRIGMAN (*North Carolina Sta. Bul. 304 (1936), pp. 16, figs. 6*).—This study was undertaken at the Coastal Plain and Mountain Branch Stations to determine whether or not the lowering of the protein level of the open formula developing mash recommended by the State extension office could be accomplished without delaying the development of the birds. Rations containing three different protein levels were fed.

The results showed no significant difference in the development of the body weight, time required for sexual maturity, or pullet year production for the groups of birds fed mashes with the different protein levels. In general, it appeared that the high protein level of 17.5 percent was not warranted and that a level of 15 percent gave just as satisfactory results. There appeared also to be a possibility of still further reduction in the protein level without injury to the future performance of the birds.

Ground soybeans as a protein supplement for laying birds, A. E. TOMHAVE and C. W. MUMFORD (*Delaware Sta. Bul. 197 (1936), pp. 37, fig. 1*).—Data are reported on the influence on egg production of replacing part or all of the meat scrap and dried buttermilk by ground soybeans in the rations of pullets and laying hens in six experiments. The results showed that reduced egg production followed the replacement of meat scrap and buttermilk by ground soybeans. The decrease was especially important when more than 6.8 percent of soybeans were included in the rations. The reduced egg yield was not due to the higher fat content of the beans. Ground soybeans had no effect on the storage quality and breaking strength of the eggs. In the studies with yearling hens soybeans furnished a more satisfactory replacement. They did not consistently lower production, and there was no effect on hatchability.

Eight years' experiences with losses of pullet layers, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bimo. Bul. 180 (1936), pp. 63–69, fig. 1*).—Over an 8-yr. period various sanitary management tests were conducted with chicks, pullets, and layers in an effort to reduce losses from infections. In addition, day-old chicks were shipped to two of the county experiment farms where they were brooded and the pullets raised until about ready to lay. At this time one-half of them were returned to Wooster for observation.

The various management tests failed to protect the chicks and growing pullets from exposure to infection. However, this protection seemed to be afforded by shipping the day-old chicks to the farms, where there was no infection, and raising them there. Disposal of all older birds 2 to 4 weeks before starting day-old chicks appeared to be the most effective means for the control of disease. In spite of all the control measures undertaken, chicks raised on the same farm with older birds became infected. Ready-to-lay pullets or pullets about 5 mo. old appeared to be resistant or immune to disease. The breeding birds in the station flock did not transmit diseases to their offspring.

Appended are (1) a discussion of disease carriers v. soil and premises as a means of disease transmission and (2) a summary of recommendations based on present knowledge.

Summer broiler production, R. S. DEARSTYNE, H. D. SMITH, and H. P. BRIGMAN (*North Carolina Sta. Bul. 303 (1936), pp. 16, figs. 3*).—During 1934 and 1935 five groups of chicks were hatched and carried through the fattening batteries. The birds were kept for 10 days in starting batteries, placed on native range, and then returned to batteries for an intensive fattening period of about 9 days. The work was carried on at the Mountain Branch Station.

The tests showed that where an economic electric rate existed starting batteries were justified in broiler production. Gains of 50 and 81 percent were made with lots of 825 and 1,037 chicks on a mash intake of 2.2 and 2.9 oz. per chick, respectively, in starting batteries. With adequate ventilation the batteries could be successfully used during the summer season. Range studies showed no correlation between season and mortality. As the season advanced there appeared to be a decrease in mash consumption and an increase in grain consumption, and this was reflected in a greater number of days required to bring late-hatched birds to the same weight as early-hatched birds. The gain per unit of feed intake on range showed no relation to season.

In 1934 cockerels fattened on rations with skim milk as the animal protein supplement gained 24.5 percent body weight as compared with 22.6 percent on a similar ration in which meat scrap was used as the animal protein. In 1935 the gain on the milk ration was 19.5 percent and on the meat scrap ration 17.5 percent. Pullets fed the milk ration in 1934 gained 26.4 percent body weight and those on meat scrap 18.6 percent, while in 1935 the gains were 23.5 and 20.5 percent, respectively.

Time interval between eggs of Rhode Island Red pullets, F. A. HAYS (*Jour. Agr. Res. [U. S.], 52 (1936), No. 8, pp. 633–638, figs. 3*).—A group of 409 pullets was trap-nested hourly at the Massachusetts Experiment Station for a full laying year to obtain data on the relationship between the time interval between eggs within the clutch and some important fecundity and reproductive characters.

The shortest interval between eggs was reached during the month of April, while the greatest time interval occurred during the months of lowest production. During the winter short time intervals were characteristic for birds showing large clutch size. Maximum egg weight in the hatching season occurred in birds averaging 25.5 hr. between eggs to March 1. When the time interval was above or below this point there was a decrease in egg size, and there were indications that such a condition was associated with low hatchability. Each increase in winter time interval tended to be followed by decreased persistency. Short winter time interval was definitely associated with high annual egg production, and may have a definite value in predicting the egg record for the pullet year.

Winter pause in Rhode Island Reds, F. A. HAYS (*Massachusetts Sta. Bul. 329 (1936), pp. 11, fig 1*).—A study was made of certain environmental and hereditary characters to discover what effect they might have on the presence or absence of winter pause and on the duration of winter pause in production-bred Rhode Island Reds.

Birds hatched in March showed a somewhat higher incidence of winter pause than those hatched in April. Date of hatching gave a negative correlation with pause duration of 0.2366 ± 0.0242. Neither age nor body weight at first egg was associated with pause duration. Short intervals between eggs of a clutch during any winter month, large winter clutch size, and ability of pullets to lay large numbers of eggs before pausing had a tendency to shorten the winter pause. A significant reduction in pause duration was in general associated with long periods of previous egg production. Short pauses were likely to be

followed by greater egg production than were long pauses. Winter pause significantly reduced winter egg production. The mean winter egg record for pause birds was 78.95 and for nonpause birds 102.9. The mean body weight from housing up to March 1 was practically the same for pause and nonpause pullets and showed no relationship to pause duration. Pauses of less than 7 days' duration were probably due to different causes than longer pauses. Laying-house mortality was not reduced nor was hatchability increased by the presence of winter pause.

Incubation experiments with turkey eggs, J. H. MARTIN and W. M. INSKO, JR. (*Kentucky Sta. Bul. 359 (1935), pp. 151–177, figs. 4*).—Data are reported on the embryonic temperature of turkey eggs incubated naturally and in forced-draft and sectional incubators. These data showed the embryo temperatures of eggs in the incubators to be slightly below those naturally incubated during the first and second weeks. Studies on growth and mineral metabolism showed practically no change until about the twelfth day, when weight increases were noted. Mineral changes were observed from the seventeenth to the eighteenth days of the incubation period.

The critical stages for mortality were early in incubation, with a second critical stage near the latter part of the incubation period. The best hatch, 77.4 percent, was obtained in a sectional incubator with temperatures during the incubation period of 100.5°, 101.4°, 102.6°, and 103° F. during the first, second, third, and fourth weeks, respectively, as contrasted with other temperature variations. The position of the egg was not related to hatchability, but the eggs should be turned at least four times daily during artificial incubation.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle in Hawaii] (*Hawaii Sta., Anim. Husb. Div. Prog. Notes No. 14 (1936), pp. 2–14*).—The results obtained in tests with dairy cattle are reported on the milk and butterfat production of the dairy herd, by G. W. H. Goo; the results of the agglutination abortion tests, by L. A. Henke; the composition and bacteriological content of the milk produced by the university dairy herd; pineapple bran v. beet pulp as supplements to grain rations for dairy cows; the value of a cassava-coconut oil cake meal combination for dairy cattle; rations using maximum amounts of pineapple bran and cane molasses; green alfalfa v. green Sudan grass; Napier grass fed whole v. cut Napier grass as a roughage; and green Napier grass v. green Sudan grass as roughages.

[Studies in dairying at the North Louisiana Substation], S. STEWART (*Louisiana Sta., North Louisiana Sta. Rpt. 1935, pp. 21–24*).—Results obtained in tests to determine how dairying and feed production can supplement cotton farms are reported, together with data on pasture studies and the value of a trench silo. These studies were made in cooperation with R. H. Lush.

[Investigations with dairy cattle and dairy products in Massachusetts] (*Massachusetts Sta. Bul. 327 (1936), pp. 16, 35, 36, 37*).—Data obtained in tests with dairy cattle are reported on the proper supplementary ration for milking cows on pasture, by J. G. Archibald, V. A. Rice, R. C. Foley, and C. H. Parsons.

Tests with dairy products yielded information on the effect of high initial aging temperatures on the basic viscosity and gel strength of gelatin solutions, by W. S. Mueller; some factors affecting the properties of whipped cream, by Mueller, M. J. Mack, and H. G. Lindquist; and the changes that occur in the storage of frozen sweet cream, by Lindquist.

[Investigations with dairy cattle and dairy products in New Hampshire] (*New Hampshire Sta. Bul. 289 (1936), pp. 4, 5, 6, 7, 15, 20*).—Data obtained in studies with dairy cattle are reported on digestion experiments with oat hay, the lability of the dairy cow's basal metabolism, and the effect of feeds on rumination of cows, all by E. G. Ritzman and F. G. Benedict; and a study of the economics of dairy herds in the southern part of the State, with special reference to diseases, by H. C. Grinnell.

Experiments with dairy products yielded data on the hemolytic streptococci in pasteurized milk, by L. W. Slanetz; and abnormal relationship of fat to solids-not-fat in milk, by H. C. Moore.

[Experiments with dairy cattle and dairy products in North Dakota] (*North Dakota Sta. Bul. 286 (1935), pp. 48–55*).—Investigations with dairy cattle produced results on barley v. corn for dairy cows, breeding dairy cattle—pure for high production, the value of tankage v. cottonseed meal as a feed for dairy cows, and performance in shed barns v. dairy barns, all by J. R. Dice; and the results of 4 yr. of a Holstein breeding circuit, by H. Buss.

With dairy products information was obtained on the influence of various methods of the partial neutralization of sour cream on butter, varying pasteurization exposures upon butter, and various flavor- and aroma-producing substances on butter, all by C. Jensen; and a study of ice wells in farm refrigeration.

[Investigations with dairy cattle and dairy products at the Wisconsin Station] (*Wisconsin Sta. Bul. 435 (1936), pp. 44–52, 68–78, 85–87, figs. 2*).—Investigations with dairy cattle are reported on the effect of different types and amounts of protein and minerals in home-grown rations upon growth and milk production, by I. W. Rupel, G. Bohstedt, and E. B. Hart; the keeping qualities and storage value of chopped hay, by F. W. Duffee, L. F. Graber, Bohstedt, B. H. Roche, and Hart; and the feasibility of ensiling alfalfa by the A. I. V. method and the use of molasses instead of mineral acids for preserving it, by W. H. Peterson, Hart, H. R. Bird, Bohstedt, W. M. Beeson, Rupel, and E. B. Fred.

In nutrition studies with dairy cattle, data are given on the addition of grass juice, liver, or brain material for improving the growth-promoting qualities of winter milk, by C. A. Elvehjem and Hart; the necessity for fat in the efficient utilization of lactose, by E. J. Schantz, Elvehjem, and Hart; and the use of iron and copper in curing goat's milk anemia, by G. O. Kohler, Elvehjem, and Hart.

With dairy products, information was obtained on the factors responsible for unusual flavors in irradiated milk, by K. G. Weckel, H. C. Jackson, R. Haman, and H. Steenbock; the relation of the irradiated flavor to constituents of milk, by Weckel and Jackson; a test to measure the stability of butterfat to oxidation, by V. C. Stebnitz and H. H. Sommer; a comparison of various new materials with copper in heat transference when used in dairy plant equipment, by L. C. Thomsen; a study of various emulsifiers for processed cheese, by H. L. Templeton and Sommer; controlling bitterness in Cheddar cheese resulting from acidity in the curd-making process, by C. A. Phillips and W. V. Price; a study of the yeasts causing a gas defect in cream cheese, by W. J. Corbett, W. C. Frazier, and Price; acidity in the manufacture of cream cheese, by Z. D. Roundy and Price; the inaccuracy of the methylene blue test for measuring the bacterial content of milk from mastitis-infected cows, by E. G. Hastings; and the relation between abnormal milk and mastitis, by Hastings and F. B. Hadley.

Producing better dairy cattle, H. S. WILLARD and W. L. QUAYLE (*Wyoming Sta. Bul. 215 (1936), pp. 20, figs. 4*).—The history of the development of the present university Holstein-Friesian dairy herd at Laramie, Archer, Afton, and Lyman is reported. In the development of these herds 12 sires were used, 7 of which sired daughters which averaged more butterfat than their dams. It is pointed out that in developing a herd constant attention must be given to the selection of superior sires and in culling low-producing cows if improved production is to be attained.

All-year pasturing with and without concentrates for dairy cattle, B. P. HAZELWOOD (*Tennessee Sta. Circ. 58 (1936), pp. 4, fig. 1*).—This study was undertaken to determine the practicability of producing milk when no grain was fed to cows supplied with all-year pasture, alfalfa hay, and silage. The pasture used consisted of crimson clover for late fall, winter, and early spring use, and permanent pasture supplemented with Sudan grass for the remainder of the year. Alfalfa hay was available all the year when the cows were in the barn. The silage used was corn and sorghum, which was fed at the rate of about 3 lb. per 100 lb. of live weight. The cows receiving grain were fed at the rate of 1 lb. of mixture per 3 lb. of milk produced.

Over a period including 5 winters an average of 340 days of pasture was available out of every 375 days' lactation. The butterfat production of the cows receiving no grain was 92 percent of that of the cows fed grain. The no-grain cows obtained 74 percent of their feed supply from pasture as compared with 52 percent for the grain-fed cows. There was no apparent difference in the physical conditions of the two groups.

Wet feeds versus dry feeds for milk production, A. D. PRATT (*Virginia Sta. Bul. 301 (1936), pp. 10, fig. 1*).—The results are reported of double reversal comparisons of dried commercial sugar beet pulp with moistened sugar beet pulp, and corn silage with corn silage artificially dried, for milk production.

The results indicated that the nutritive values of dried and wet beet pulp and normal and artificially dried corn silage were approximately equal when considered on a dry matter basis. The greater water intake of the cattle receiving the wet feeds did not influence milk production.

Pea vine silage as a feed for dairy cattle, J. O. TRETSVEN (*Montana Sta. Bul. 317 (1936), pp. 11*).—In two trials conducted by the reversal method with 16 cows in each trial, a comparison was made of pea vine silage fed with alfalfa hay and concentrates according to production and the alfalfa hay and concentrates fed alone. Production was approximately equal on the two rations. When fed under suitable precautions, the pea vine silage had no influence on the flavor of the milk produced. Two trials with dairy heifers also showed similar results for rations with and without pea vine silage. For milk production and growth the silage was worth approximately one-third the value of alfalfa hay.

Pathology of rickets in dairy calves, H. E. BECHTEL, E. T. HALLMAN, C. F. HUFFMAN, and C. W. DUNCAN (*Michigan Sta. Tech. Bul. 150 (1936), pp. 47, figs. 34*).—A description is given of the histological changes in 11 dairy calves from 151 to 520 days of age which were suffering from vitamin D deficiencies in comparison with 5 normal calves. The changes in the bones were accompanied by decreased concentrations of calcium and/or inorganic phosphorus in the blood plasma. The best index of rachitic changes in the skeleton was observed in the picture of the costochondral junction at the ventral end of the rib. Other changes in the histology of bone formation were described. More severe symptoms of rickets were associated with more rapid growth. Abnormal accumulations of bile were observed in several of the calves at post mortem, and enteritis occurred in a few cases.

Maintenance of grade A milk: A study of the factors affecting quality, returns and premium losses, E. H. RINEAR and H. C. MOORE (*New Hampshire Sta. Bul. 291 (1936), pp. 24, figs. 2*).—This study of the factors affecting quality, returns, and premium losses is based principally on data for 1931, 1932, and 1933, secured from 82 grade A and 20 grade B producers shipping milk to Boston through the Pattee receiving station at West Canaan, N. H., and records from 24 producers of Monroe, N. H., from which place only B grade milk was shipped.

The average premiums paid to grade A producers ranged from $196 58 in 1931 to $142.07 in 1933. The premiums during the 3 yr. studied represented 12 to 14 percent of the gross milk receipts. Little correlation was found between the dairy scores made by the inspector for the Boston Board of Health and the bacteria counts of the same grade A producers. Of the producers having high bacteria counts, the loss of premiums was traced to a lack of sterilizing the equipment for 38 percent, poor cooling for 20 percent, gargety milk for 21 percent, and labor problems for 13 percent. From 1931 to 1933, troubles from improper sterilization and cooling declined but the trouble with gargety milk increased. The most important differences between grade A and grade B producers were in milking practices, washing and sterilizing of equipment, amount of ice used, and time used in sterilizing.

Twenty-first annual report of the creamery license division, T. H. BINNEY (*Indiana Sta. Circ. 215 (1936), pp. 16, fig. 1*).—This is the usual report of the State creamery license division for the year ended March 31, 1935 (E. S. R., 73, p. 535). The report deals with the comparative annual production of dairy products in Indiana, the creamery inspection, and the examination of testers.

VETERINARY MEDICINE

[Report of work in animal pathology by the Massachusetts Station] (*Massachusetts Sta. Bul. 327 (1936), pp. 74–78*).—In reporting for the year (E. S. R., 73, p. 676) reference is made by H. Van Roekel, K. L. Bullis, O. S. Flint, and M. K. Clarke to the progress of pullorum disease eradication work, a report of which has been noted (E. S. R., 74, p. 400), pullorum disease investigations, diagnostic service, flock morbidity and mortality studies, "epidemic tremors" in chickens, and disease studies in ruffed grouse. Additional work with laryngotracheitis and colds is reported upon by C. S. Gibbs, and on differentiation of the pathological cell in neurolymphomatosis from lymphocytes of the blood of chickens, the differentiation of neurolymphomatosis from lympholeucosis, and a study of "pearly eye" in neurolymphomatosis, all by Gibbs and C. G. Johnson.

[Report of work in animal pathology by the North Dakota Station] (*North Dakota Sta. Bul. 286 (1935), pp. 23–26, 47*).—The work for the period 1932–35 referred to (E. S. R., 67, p. 739) includes avian tuberculosis, by G. S. Harshfield, L. M. Roderick, and M. C. Hawn; feed lot losses among lambs, by Roderick, Harshfield, and Hawn; pregnancy disease of sheep, by Roderick, Harshfield, Hawn, and T. H. Hopper; infectious proventriculitis of turkeys, by Hawn; sweetclover disease of cattle, by Roderick; the Bang's disease control program, by Hawn, Harshfield, and Roderick; and prussic acid poisoning by grain- and sweet-sorghum and Sudan grass, by Hopper, L. L. Nesbitt, and A. J. Pinckney.

[Report of work in animal pathology and parasitology by the Wisconsin Station] (*Wisconsin Sta. Bul. 435 (1936), pp. 21, 22, 25–27, 54–56, 79, 80*).—The work of the year in animal pathology and parasitology referred to (E. S. R., 74, p. 539) includes the question of transmission of Bang's disease by casual

reactors that mingle with susceptible animals, by B. A. Beach and G. C. Humphrey; the development of a rapid chlorine test for mastitis, by E. R. Carlson; factors affecting the control of coccidiosis, by C. A. Herrick, G. L. Ott, J. G. Halpin, and C. E. Holmes; a study of the effects of internal parasites on egg production and hatchability, by Herrick, Halpin, and Holmes; the mechanics of selenium poisoning traced to effects on enzyme systems, by V. R. Potter and C. A. Elvehjem; and limitations of the tuberculin test, by E. G. Hastings, J. McCarter, and Beach.

[**Livestock diseases in Jamaica**], S. Lockett (*Jamaica Dept. Agr. Ann. Rpt., 1934, pp. 13–20*).—The occurrence of and control work with bovine tuberculosis, infectious bovine abortion, cattle tick fever, and other diseases of livestock are reported upon.

Annual report of the Civil Veterinary Department, Bihar and Orissa, for the year 1934–35, P. B. Riley (*Bihar and Orissa Civ. Vet. Dept. Ann. Rpt., 1934–35, pp. [81], pl. 1*).—An account of the occurrence of and control work with infectious and parasitic diseases of livestock takes up a large part of this report (pp. 10–21, 27–33).

Report on the Veterinary Department, Burma, for the year ending the 31st March 1934, D. T. Mitchell (*Burma Vet. Dept. Rpt., 1933–34, pp. [2]+28, pls. 5*).—A brief account of the occurrence of and control work with diseases of animals and of veterinary research is included in this report (E. S. R., 71, p. 241).

[**Work in animal pathology in Mysore**], S. D. Achar (*Mysore Serum Inst. Ann. Rpt., 1935, pp. 11*).—This report of work with infectious diseases of livestock in Mysore deals particularly with the biological products that may be used against rinderpest, hemorrhagic septicemia, anthrax, blackleg, and sheep pox, the details of which are presented in table form.

Animal health investigations, G. A. Julius et al. (*Austral. Council Sci. and Indus. Res. Ann. Rpt., 9 (1935), pp. 34–41*).—The work of the year 1934–35 (E. S. R., 73, p. 678) with infectious diseases and parasites of livestock is reported upon.

[**Contributions on animal pathology and parasitology**] (*Onderstepoort Jour. Vet. Sci. and Anim. Indus., 5 (1935), No. 2, pp. 363–471, figs. 3*).—The contributions here presented (E. S. R., 74, p. 539) are as follows: The Bloedpens Strain of *Cl[ostridium] welchii*, Type B, Wilsdon (the "Lamb Dysentery Bacillus") (pp. 363–389) and The Production of Immunity Against *Cl[ostridium] welchii*, Type B, Wilsdon (the "Lamb Dysentery Bacillus") (pp. 391–416), both by J. H. Mason; The Chemotherapy of Oesophagostomiasis in Sheep, II, by H. O. Mönnig (pp. 419–438); The Toxicity of Pumpkin Seed (*Cucurbita pepo* L.), by D. G. Steyn (pp. 441–443); The Occurrence of Cyanogenetic Glucosides in South African Species of *Acacia*—II, Determination of the Chemical Constitution of Acacipetalin: Its Isolation from *Acacia stolonifera* Burch., by C. Rimington (pp. 445–464); and The Toxicity of Trypan Blue, by D. G. Steyn (pp. 467–471).

Immunity, premunition, and natural resistance [trans. title], E. Sergent and L. Parrot (*Arch. Inst. Pasteur Algérie, 13 (1935), No. 3, pp. 279–319, fig. 1*).—Attention is drawn to the differences between immunity and premunition, the latter being conferred artificially only by living virus vaccines.

Premunition and premunitive vaccination in veterinary pathology [trans. title] A. Donatien and F. Lestoquard (*Bul. Acad. Vét. France, 8 (1935), No. 2, pp. 125–131; abs. in Vet. Rec., 16 (1936), No. 5, pp. 112, 113*).—In the course of this discussion it is pointed out that while the premunition form of immunity plays an important part in decreasing the economic importance of

certain diseases, the premune animal remains a permanent reservoir of infection and a potential danger to all susceptible animals in the neighborhood.

Bact. aertrycke endotoxin: A study on its production, detoxication, and the practical utilization of its antigenic properties, E. GRASSET, A. ZOUTENDYK, and A. SCHAAFSMA (*Brit. Jour. Expt. Path., 16 (1935), No. 5, pp. 454–460*).—In the study of a recently isolated and highly virulent strain of *B. aertrycke* responsible for an acute outbreak of food infection, a potent endotoxin was obtained by alternate freezing and thawing of concentrated killed emulsions.

"The toxic autolysates were rendered atoxic by the action of 0.6 percent of formalin in the course of 6 weeks' incubation at 37° C. The antigenic properties of the detoxicated autolysates have been demonstrated by the immunization of mice and rats. The hyperimmunization of horses gave rise to sera possessing specific and high agglutinating properties, flocculating properties, and considerable antibacterial and antitoxic values as proved by tests in vivo and in vitro. The concentration and refinement of the horse serum is now being investigated. The investigation tends to show that the [*B.*] *aertrycke* antiserum may be utilized with satisfactory therapeutic results should the necessity arise."

Observations on Myxomatosis cuniculi (Sanarelli) made with a view to the use of the virus in the control of rabbit plagues, C. J. MARTIN (*Austral. Council Sci. and Indus. Res. Bul. 96 (1936), pp. 28, figs. 2*).—A study of the epidemiology of a highly specific virus found to affect only the European rabbit (*Oryctolagus*) and its domesticated varieties is reported upon. The two strains of the virus were used in the experiments, one of low and variable virulence and the other of higher and more fixed virulence.

The prevention of myiasis in wounds of domestic animals by the use of "bone oil", J. A. HOWARTH (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 628, 629*).—In work conducted in California during the summer and fall of 1935 the author obtained satisfactory results in protecting open wounds in cattle, sheep, horses, and hogs from flesh flies through applications of bone oil. Following the use of benzol for the destruction and removal of larvae from wounds infested with the screwworm (*Cochliomyia macellaria*) and other maggots, bone oil was applied. In no case was there a reinfestation of the wound, and healing was exceptionally rapid showing no detrimental effect of the bone oil on the tissue. In one case th's repellent was successfully used on the wound of a sheep where the raw surface had an area of approximately 1 sq. ft. There appeared to be no absorption of toxic material, and healthy granulation and repair took place without an excessive amount of exudate. From the success in treating wounds already infested, it appears that the use of bone oil in immediately coating wounds caused by castration, dehorning, branding, shearing, barbed-wire cuts, etc., would be an effective safeguard against myiasis. It is thought that the product can be marketed at a price which will render it practical for extensive use in the animal industries.

Timber milk vetch as a poisonous plant, I. E. NEWSOM, F. CROSS, B. R. MCCRORY, A. H. GROTH, J. W. TOBISKA, E. BALIS, L. W. DURRELL, E. C. SMITH, and E. N. STOUT (*Colorado Sta. Bul. 425 (1936), pp. 42, figs. 7*).—Studies of a chronic disease of cattle running on summer range on Blue and Douglas Mountains in the extreme northwestern part of Colorado, which develops in the late summer and manifests itself mostly in lactating animals, are reported upon. The more prominent symptoms include incoordination of gait, weaving, clicking the heels together, emaciation, weakness, husky voice, the urine passed in spurts on driving, and, finally, paralysis and death. Poisoning by the timber milk vetch (*Astragalus hylophilus*) growing on the range having been

suspected, feeding experiments were conducted which led to the production of the disease in both cattle and sheep. It then developed that severe losses in sheep in the same territory, which had not been associated with cattle loss because they were more acute, could also be attributed to the same weed. Numerous examinations of the forage to determine whether selenium played any part were negative. No toxic substance was demonstrated by feeding either the plant itself or the watery or alcoholic extracts to guinea pigs.

Colorimetric methods for determination of inorganic calcium and phosphorus in blood serum, a method for determination of available calcium and phosphorus in soils (CO_2 extraction method), and a method for calcium and phosphorus in grasses and herbage are taken up in an appendix.

Reticuloendothelial proliferations in domestic animals, H. BERTHELSEN (*Skand. Vet. Tidskr., 26 (1936), No. 3, pp. 146–168, pls. 2; Eng., Swed. abs., pp. 165, 166*).—Cases of reticuloendothelial proliferations in the dog, cat, foal, fox, and cow are reported upon.

The ticks and the diseases which they transmit to domestic animals in Madagascar [trans. title], G. BÜCK (*Rev. Agr. Maurice, No. 84 (1935), pp. 196–209, pls. 6*).—The first part of this contribution deals with the principal ticks of Madagascar (pp. 196–198), the second part with the diseases of animals on the island transmitted by ticks (pp. 198–207), and the third part with the means of tick control and disease prevention (pp. 207–209).

Spontaneous virus diseases in common laboratory animals: Mice, rats, cats, and monkeys, J. THOMPSON (*Arch. Path., 21 (1936), No. 4, pp. 531–540*).—The various diseases caused by viruses and analogous conditions in mice, rats, cats, and monkeys are briefly summarized by the author. "In the past experimental studies have been devoted almost exclusively to the investigation of the more pathogenic viruses. However, those which do not show distinctive clinical signs are of interest. That such viruses may be potentially pathogenic should not be overlooked. The recent demonstration of an etiologic factor in two cases of aseptic meningitis in man identical with the virus-producing lymphocytic choriomeningitis in mice and monkeys, as well as the isolation of virus B from a person in whom an ascending paralysis developed and who died following a bite from a monkey, suggests that the animal kingdom is an incompletely probed reservoir of human virus disease."

Studies on hemolytic streptococci.—I, Methods of classification, A. C. EVANS (*Jour. Bact., 31 (1936), No. 4, pp. 423–437*).—The methods used by the author for the study of 573 strains of hemolytic streptococci are described, the value of the various tests for classification purposes is discussed, and a few relatively simple tests are selected by which unknown strains may be identified with species to be described in subsequent papers of this series. A list of 36 references to the literature is included.

Salmonella enteritidis (Gärtner) and its varieties [trans. title], E. SAVINO (*Rev. Inst. Bact. [Argentina], 6 (1935), No. 5, pp. 677–686*).—A report is made of the study of the seven varieties of *S. enteritidis*, namely, *enteritidis, danysz, chaco, essen, dublin, rostock*, and *moscú* (*moscow*), with a list of 33 references to the literature.

Rocky Mountain spotted fever, with special reference to the disease in Maryland, C. H. HALLIDAY (*Md. Conserv., 13 (1936), No. 2, pp. 3–7, figs. 6*).—A tick survey in Maryland is said to have shown the American dog tick, a transmitter of the infection, to be widely distributed, having been found in the adult stage on dogs, horses, cattle, and man.

The pathogenic action of Trichomonas foetus on the central nervous system [trans. title], S. NICOLAU and A. LWOFF (*Ann. Inst. Pasteur, 55 (1935),*

No. 6, pp. 654–675, figs. 24).—The rabbit, guinea pig, mouse, rat, dog, monkey, and fowl have been found to be susceptible to *T. foetus* when inoculated intradurally. In all of these except the rat such infection produces a peracute, acute, or chronic meningoencephalomyelitis. The organism shows a predilection for the cerebral ventricles, with a tendency to destroy the cerebral tissue.

The effect of low temperature upon trypanosomes (Trypanosoma equiperdum) in the organism of mammals, N. P. KALABUCHOV and L. B. LEVINSON (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 1 (1936), No. 1, pp. 47–50*).—Experiments are reported in which two species of bats (*Nyctalus noctula* Schr. and *Pipistrellus nathussi* Keys & Blas.) were infected with *T. equiperdum*, which multiplied very quickly. It was found that at a temperature ranging from 3° to 4° C. (body temperatures of from 3.5° to 6.7°), infection in the bats did not develop at all, and did not develop later when the bats were warmed. Placed in ice boxes on the third or fifth day after the number of trypanosomes in the blood had reached a high level, they disappeared and failed to reappear in the blood after exposure to normal temperatures.

Intracerebral inoculation of fetal guinea pigs with Bacille Calmette-Guérin and the H_{37} strain of tubercle bacillus, I. S. NEIMAN and O. C. WOOLPERT (*Amer. Jour. Path., 12 (1936), No. 2, pp. 153–164, pl. 1*).—The authors report upon studies in which "guinea pig fetuses were inoculated with graded doses of B. C. G. and the effects compared with those obtained in a similar series inoculated with virulent tubercle bacilli (H_{37}). Both types of tubercle bacilli were found to spread from the site of inoculation but not with equal rapidity; with the same dose, it took a longer time for B. C. G. to cause as much pathology, in the animal as a whole, as H_{37}. Pathologically the response of the fetus to both organisms was the same. Histological evidence has been brought forward to show that B. C. G. is capable of multiplying in fetal tissues and of initiating a disease process different only in degree from that produced by H_{37}. So far, attempts at fetus-to-fetus transfer of B. C. G. have not been successful. Recovery of this bacillus on artificial media from inoculated fetuses was accomplished 4 times in 24 attempts."

Bovine pulmonary tuberculosis in man: Twenty-six cases from Copenhagen, F. TOBIESEN, K. A. JENSEN, and H. C. A. LASSEN (*Tubercle, 16 (1935), No. 9, pp. 385–396; abs. in Arch. Path., 21 (1936), No. 5, p. 706*).—The report here presented includes 26 cases of bovine pulmonary tuberculosis occurring in København (Copenhagen) from February 1931 to July 1933. Ten of the patients were under 5 yr. of age and none over 32 yr. Thirteen of the 26 patients had been drinking raw milk for some time, while only 3 denied they had ever taken raw milk. "In 18 of the 26 cases the tubercle bacilli were cultivated from gastric lavage alone. Sources of error with this method are mentioned and discussed. Six of the patients died within the observation period (concluded in April 1934), and all 6 died of generalized tuberculosis; 3 of them were under 5 yr. of age, 2 between 5 and 15 yr., and 1 over 15 yr. . . . It seems evident . . . that the prognosis of bovine pulmonary tuberculosis in the age-class under 5 yr. is serious, probably just as serious as the prognosis of pulmonary tuberculosis due to the human type of the bacillus."

Family tuberculosis due to bovine tubercle bacilli, A. S. GRIFFITH and W. T. MUNRO (*Brit. Med. Jour., No. 3890 (1935), pp. 147–150*).—Although some 80 human cases of pulmonary tuberculosis due to the bovine type of the organism had been discovered in Great Britain by the close of 1933, no evidence had been obtained of the transmission of the bovine tubercle bacillus from one human to another.

Investigations in 1934, here reported upon, give the details of two families, each of which contained two cases of phthisis pulmonalis in adults and one, in addition, a case of glandular tuberculosis in a child, all due to tubercle bacilli of the bovine type.

Bovine phthisis, its incidence in north-east Scotland, A. S. GRIFFITH and J. SMITH (*Lancet [London], 1935, II, No. 24, pp. 1339–1342*).—Reference is made to the isolation of the bovine type of the tubercle bacillus from 13 of 103 cases of pulmonary tuberculosis in human beings in Scotland.

A peculiar selective site of Bacillus pyogenes in dairy cows, G. MARTINAGLIA (*Jour. So. African Vet. Med. Assoc., 6 (1935), No. 1, pp. 39, 40, fig. 1*).—The author reports having found this organism associated with various suppurations, disease processes, and certain types of mastitis in dairy herds, it being of wide distribution in the Transvaal and of common occurrence in various suppurating processes in dairy cattle. Particular mention is made of its presence in a large induration on the supraposterior aspect of the udder of young heifers shortly before and after calving. It has not been encountered in the milk drawn from the affected udders and appears to be confined to the subcutaneous tissue between the hindquarters of the udder.

A survey of the incidence of Brucella in pasteurized and unpasteurized market milk in Illinois, R. GRAHAM and J. P. TORREY (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 614–623, fig. 1*).—During the course of work in Illinois *Brucella* was isolated by guinea pig inoculation from 50 percent of 62 raw milk samples collected at milk depots in 28 widely scattered counties in Illinois. The samples inoculated were taken from vats of pooled milk representing composites of many different cows or herds. The percentage of infection encountered in pooled milk, though seemingly high, may be explained from the fact that contaminated milk is composited with uncontaminated milk upon entering the pasteurizing vat. Milk from a single infected cow may contaminate the entire pool. Pasteurization, as employed in five different types of pasteurizers, effectively destroyed *Brucella* in 31 milk samples. These results suggest the prevalence of *Brucella* in raw pooled milk and the value of pasteurization, as employed in milk depots furnishing samples, in destroying *Brucella*. *B. abortus* is apparently the most prevalent type in raw milk in Illinois.

A list of 25 references to the literature is included.

Kinky tail in cattle, M. W. EMMEL and B. KNAPP, JR. (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 630–632, figs. 4*).—The authors' study at the Florida Experiment Station indicates that kinky tail is an inherited character. It is concluded that operation would be advisable only in instances in which the animal is to be used for show purposes.

Mastitis.—III, The identity of Streptococcus agalactiae, P. A. HANSEN (*New York State Sta. Tech. Bul. 232 (1935), pp. 52, pls. 2*).—In continuation of work with mastitis (E. S. R., 68, p. 813), the author reports the results of studies of 94 cultures secured from laboratories that have investigated the cause of ordinary bovine mastitis. These cultures, together with 149 strains freshly isolated from cows infected with bovine streptococcus mastitis, were given comparative study. The results of the studies on the freshly isolated and stock strains of the mastitis streptococcus indicate that the majority of the strepococci associated with ordinary bovine mastitis are of one general type. It is concluded that the preferable name for this streptococcus is *S. agalactiae* Lehm. and Neum. (1896). Its most significant characteristics, which differentiate it from other closely related species of streptococci, are its acid production from maltose, sucrose, and dextrin with no acid production

from mannitol, sorbitol, arabinose, xylose, raffinose, inulin, and amygdalin. It attacks sodium hippurate, does not split esculin, and produces either a viridans or narrow-zone type of hemolysis on blood agar plates. It curdles litmus milk before reduction, reduction progressing afterwards slowly from the bottom upwards. A few strains of a less frequent type *S. uberis* Diernhofer were noted and found to differ from *S. agalactiae* by the fermentation of sorbitol, inulin, and amygdalin, the hydrolysis of esculin, and slow acid production in milk. Action on litmus milk, sodium hippurate, and esculin are recommended as rapid presumptive tests for the differentiation of streptococci isolated from quarter samples.

A seven-page list of references to the literature is included.

Observations on the preventive and curative treatment of bovine pleuropneumonia [trans. title], G. CURASSON (*Bul. Acad. Vét. France, 8 (1935), No. 7, pp. 352–358; abs. in Vet. Rec., 16 (1936), No. 5, p. 112*).—Reference is made to work with formolized vaccine, which has been employed in French West Africa with some success, and to Pirani's modified formolized vaccine, which failed to protect. Mixtures of the virus and saponin gave very promising results, and it is concluded that if his results are confirmed this method will prove to be the simplest and most effective. Novarsenobenzol, although of little use in peracute and massive infections, is considered to be a specific remedy and to be the best therapeutic agent available for this disease.

The role of Trichomonas in abortion, pyometra, and sterility of the cow, M. BOURDIÉ (*Rec. Méd Vét., 112 (1936), No. 2, pp. 93–100, figs. 2*).—*Trichomonas* was found by the author to be present in 9 of 27 cases of pyometra and absent in the uteri of 30 normal cows systematically examined.

An acanthocephalid parasitic in a calf, J. H. WHITLOCK and C. C. MORRILL (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 6, pp. 764–766, fig. 1*).—The infestation of a calf received from the vicinity of Riley, Kans., by the thorn-headed worm of swine (*Macracanthorhynchus hirudinaceus*), here reported, is said to be the first record of a natural infestation of a bovine by it.

The effect of splenectomy on anaplasmosis of the sheep [trans. title], F. LESTOQUARD, A. DONATIEN, and C. SALORD (*Bul. Soc. Path. Exot., 29 (1936), No. 3, pp. 264–266*).—The effect of splenectomy is said to vary with the several blood parasites. With the Piroplasmidae, including *Piroplasma* sens. strict., *Babesiella*, and *Nuttalia*, the nonpathogenic *Theileria*, including *T. mutans* and *T. recondita*, and *Bartonella* and *Eperythrozoon*, it is followed by a temporary suspension of the premunition. In the case of the Anaplasmidae splenectomy causes a definite suppression of premunition, at least where *Anaplasma ovis* is involved. In the case of the pathogenic *Theileria*, including *T. parva* and *T. dispar*, splenectomy does not have any effect upon premunition.

The sheep nasal fly: A method of treatment for sheep infected with larvae of Oestrus ovis, R. DU TOIT and R. CLARK (*Jour. So. African Vet. Med. Assoc., 6 (1935), No. 1, pp. 25–32, figs. 2*).—A treatment which consists of an injection into each frontal sinus of 2 cc of a mixture of equal parts of carbon disulfide and liquid paraffin has been found to be safe, practicable, and efficacious when carried out in the proper way and on suitable subjects. It is not safe for sheep under 6 mo. of age.

Parasites and parasitic diseases of swine in Puerto Rico, H. L. VAN VOLKENBERG (*Puerto Rico Sta. Bul. 38 (1936), pp. 14, figs. 2*).—This contribution considers the occurrence and distribution of the parasites of swine common in Puerto Rico, the damage caused, need for shade protection, preventive measures, the bare-lot method of raising hogs, and treatment. Summarized accounts of the ecto- and endo-parasites of importance follow.

Anaplasmosis-like disease in Formosan swine, M. SUGIMOTO (*Jour. Soc. Trop. Agr. (Nettai Nôgaku Kwaishi), 7 (1935), No. 3, pp. 240–244, figs. 3*).—This contribution in Japanese, presented with a list of 15 references to the literature, describes a new species of *Anaplasma* found in swine in Taiwan under the name *A. taiwanensis.*

Intestinal emphysema in swine, H. E. BIESTER, D. F. EVELETH, and Y. YAMASHIRO (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 6, pp. 714–731, figs. 7*).—In experiments with swine conducted in Iowa, intestinal emphysema was found associated with feeding polished rice. "The kind of protein supplement did not affect its appearance when rice was fed. When corn was fed with as much as 20 percent skim milk powder by dry weight, emphysema failed to develop. The process consists of a gaseous distention of the lymph spaces involving the intestinal mucosa, submucosa, inner and outer muscle layers, serosa, mesentery, and the lymph nodes draining the affected portion. The process usually involves the entire jejunum, part of the ileum, and in some cases the terminal portion of the duodenum. In one instance cysts were found on the rectal serosa and the adductor muscles near the symphysis pubis. Vitamin B did not appear to be a factor. Bacteriologic examinations were negative. No significant hematologic deviations were associated with intestinal emphysema. Two cases of intestinal emphysema were encountered in several groups of chickens on a test ration containing rice. The blood chemistry of the swine was normal as far as it was investigated."

Epithelial diverticula in the large intestine of swine, H. C. H. KERNKAMP (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 6, pp. 732–736, figs. 3*).—Contributing from the Minnesota Experiment Station, an account is given of a histological study of the small nodular bodies of macroscopic dimensions observed during the past 15 or 20 yr. in the walls of the large intestine of swine. Previously assumed to have been produced by a nematode of the genus *Oesophagostomum,* the examination has shown the lesions to represent outpocketings of the epithelium, surrounded to a greater or less extent by lymphoid tissue. The origin of the epithelial diverticula appears to relate to the embryonal development of the pig. It is pointed out that in many of the diverticula studied, a process of necrosis was taking place which involved the epithelial structures. A liquefaction of the cryptic contents was also noted. The importance of the lesion, insofar as it relates to the well-being of the animals in which it occurs, is not definitely known at present.

Tuberculosis in a herd of hogs with one hundred per cent mortality, J. F. BULLARD (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 632–636*).—Contributing from the Indiana Experiment Station, the author reports upon an outbreak of tuberculosis in a herd of 12 sows and 68 pigs in which there was a 100-percent death rate from September to April. Autopsies were made on two field cases of this outbreak, and in each instance acid-fast organisms and tubercles were demonstrated in the various sections prepared for microscopic examination.

Animal inoculations for typing purposes, although not entirely complete, were carried out. Acid-fast organisms and tubercles were demonstrated in a rabbit that had been inoculated subcutaneously with tissue from one of the field cases. A lung emulsion, prepared from this rabbit, was injected into a pig, hen, guinea pig, and rabbit. In 15 and 13 days, respectively, the pig and guinea pig died, and each showed lesions of tuberculosis and acid-fast organisms also were found. The results of these inoculation experiments demonstrated that an acid-fast organism, apparently of the bovine type, was the

causative factor." The possibility of *Actinomyces necrophorus* playing any particular part in the outbreak was eliminated through inoculation experiments.

Encephalitis in horses, L. P. DOYLE (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 636–641, figs. 6*).—In studies at the Indiana Experiment Station an encephalopathic disease prevalent in horses in parts of the State during the fall and winter of 1934 and 1935 is reported upon. While the precise nature of this horse disease was not fully determined, the type of microscopic change found, particularly the perivascular accumulations of cells, indicates an infectious agent as the cause. The relationship between this disease and encephalomyelitis remains to be determined.

Observations on complement-fixation with distilled water-spleen antigen in equine infectious anemia, W. M. MOHLER (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 624–627*).—In this preliminary account it is pointed out that while the complement-fixation test for infectious anemia of horses (swamp fever) is still in the experimental stage, the results thus far obtained have been encouraging and are presented with the view to furthering similar diagnostic investigations of other research workers.

Horsesickness, R. A. ALEXANDER and B. VAN DER VYVER (*Jour. So. African Vet. Med. Assoc., 6 (1935), No. 1, pp. 33–38*).—During the season of 1933–34 a total of 171 horses and 28 mules were immunized under field conditions against horsesickness by means of neurotropic attenuated virus. Immunization was effected by the injection of either a single strain of virus, by successive injections of two strains, or by a single injection of a mixture of two strains. The total number of deaths following vaccination was 3, but since the animals in question died not later than the fifth day, it is believed that death was due not to the injection but to natural infection prior to immunization. This opinion is discussed. The number of breakdowns in immunity was 29; of these 2 recovered and 27 died.

Extent of vertical migration of horse strongyle larvae in soils of different types, J. T. LUCKER (*Jour. Agr. Res. [U. S.], 52 (1936), No. 5, pp. 353–361*).—In experimental work aimed at determination of the extent to which vertical migration of horse strongyle larvae in soils may occur, such information being closely related to the value of plowing under as a control means for horse strongyles, a number of infective larvae were buried, usually from 1 to 6 in. beneath the surface. They were placed in helminthologically sterile or tested larva-free clay, heavy sandy loam to clay loam, sandy clay loam, sandy loam, sandy light clay loam, and coarse sand soils. The special wooden boxes usually used as containers were kept either in the laboratory, under shelter, or outdoors. In experiments in the laboratory or under shelter, the soil was kept moist; precipitation invariably occurred during the outdoor experiments. The larvae reaching the surface in from 19 to 67 days after burial were isolated in the Baermann apparatus, counted, and their number calculated in terms of percentage of the number of larvae originally buried.

In clay soils few or no larvae were recovered at the surface; in the other soils a maximum of 1.9 percent of the larvae buried from 3 to 6 in. were recovered at the surface after from 25 to 62 days. From shallower depths the percentages of larvae reaching the surface in similar intervals were markedly higher. When feces containing an undetermined large number of infective larvae were buried from 3 to 8 in. in coarse sand, 6,920 larvae reached the surface after 28 days from a depth of 8 in. Some simultaneous lateral migration occurs during upward migration.

Assuming constancy of the rates of vertical migration shown by the experiments, it is concluded that deep plowing of infested pastures should be of some value for the control of strongyle parasitism in horses; the effectiveness of this control measure will be affected by the depth of the burial of the larvae and the type of soil in which they are present.

Diseases and parasites of poultry in California, J. R. BEACH and S. B. FREEBORN (*Calif. Agr. Col. Ext. Circ. 8, rev. (1936), pp. 110, figs. 44*).—The present status of knowledge of the important diseases and parasites of poultry as met with in California is here brought together for use by the poultryman.

[Report of work in avian pathology by the New Hampshire Station] (*New Hampshire Sta. Bul. 289 (1936), pp. 16, 24–26, 27*).—The work of the year briefly referred to includes studies of the ruptured egg yolk in the domestic fowl, by L. W. Slanetz; skin vaccination for fowl pox, and poultry autopsies, both by C. L. Martin and C. A. Bottorff; and pullorum testing, and studies in the improvement of technic for the eradication of pullorum disease, both by Bottorff.

Studies on the egg-propagated viruses of infectious laryngotracheitis and fowl-pox, C. A. BRANDLY (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 587–599*).—Studies conducted at the Kansas Experiment Station have shown that the viruses of infectious laryngotracheitis and of fowl pox may be carried through an indefinite series of developing egg passages by the methods here described, the incidence of extraneous bacterial contaminations having been materially lower than by methods heretofore described.

"Infectious laryngotracheitis virus (strain 8090), propagated through 35 series of developing chicken eggs, did not show significant modifications in virulence. The egg-propagated virus appeared equally as satisfactory as fresh tracheal exudate virus when used for protective vaccination against the disease. Fowl pox virus passed through 8 series of chicken eggs did not appear to be altered significantly in virulence for developing eggs or chickens of several ages. The chorioallantoic-cultivated pox virus used in vaccination gave satisfactory 'takes' and immunity as compared to the comb-lesion virus from nearly mature chickens. Of the species of developing eggs, other than chickens, only those of the turkey were susceptible to infectious laryngotracheitis infection. By the methods employed, negative results were obtained with pigeon, guinea fowl, and duck eggs."

A list is given of 16 references to the literature.

Lymphocytoma and fowl paralysis, R. FENSTERMACHER (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 5, pp. 600–613*).—In a study at the Minnesota Experiment Station of a fatal neoplastic-like disease of the domestic fowl, in which the pathological lesions are confined to the visceral organs and the skeletal muscles, and for which the term "lymphocytoma" has been selected as a designation by the author, 715 chicks were hatched during a 2-yr. period. The losses due to intercurrent diseases were tremendous, 58 percent of the chicks hatched during the first year and 70 percent of those hatched during the second year having succumbed as a result of diseases other than those under investigation. The term "fowl paralysis" is restricted to the condition in which the pathological lesions are confined to the eyes, nerve, and brain tissues. The data presented, the details of which are given in six tables, support the view that lymphocytoma and fowl paralysis are two separate diseases, the latter being transmissible while the former is nontransmissible. Furthermore, the two diseases may coexist in the same bird. The data suggest that heredity is a factor to be considered in the transmission of the two diseases.

A list is given of 12 references to the literature.

The etiology of fowl paralysis, leukemia, and allied conditions in animals, III, IV, M. W. EMMEL (*Florida Sta. Bul. 293 (1936), pp. 23*).—The third and fourth parts of this contribution (E. S. R., 74, p. 262) are presented.

III. *The intestinal flora of chickens affected with enteritis associated with intestinal parasitism* (pp. 5–17).—The species "*Salmonella aertrycke* was found in the intestinal contents of five birds affected with enteritis associated with coccidiosis, *S. enteritidis* in three birds, *S. typhimurium* in two birds, while *S. schottmulleri*, *S. suipestifer*, *S. pullorum*, [and] *Eberthella typhi* were found in the intestinal contents of but one bird each. Five birds did not yield cultures of paratyphoid or typhoid organisms. The percentage occurrence of these micro-organisms ranged from 8.7 to 61.4 percent of the total bacterial flora. In 18 birds affected with enteritis associated with roundworms, tapeworms, or both, *S. aertrycke* was isolated from the intestinal contents of four birds, *S. typhimurium* from two birds, while *S. enteritidis*, *S. paratyphi*, *Shigella paradysenteriae*, *E. typhi*, and *E. enterica* were isolated from the intestinal contents of but one bird each. The percentage occurrence of these micro-organisms ranged from 25.8 to 58.6 percent of the total bacterial flora. In a routine examination of selected cases eight species of *Salmonella*, one species of *Eberthella* and *Shigella*, seven unidentified cultures of *Salmonella*, and four unidentified species of *Eberthella* were isolated from 137 to 230 samples of intestinal contents of birds affected with enteritis associated with *Eimeria*, *Ascaridia*, *Capillaria*, and *Taenia*. *S. aertrycke* was the predominating organism isolated. *E*[*berthella*] *typhi* was isolated from two birds." The author was led to conclude that intestinal parasitism seriously interferes with the normal flora, allowing micro-organisms of the paratyphoid and typhoid groups to become established in the intestinal tract. It is pointed out that chickens offer a vast potential source of micro-organisms of the paratyphoid and typhoid groups, which opens a broad field for the epidemiologist interested in the relation of these micro-organisms to human health.

IV. *The pathologic manifestations of the causal micro-organisms in the fowl* (pp. 18–23).—It is concluded that all of the pathologic manifestations here described may occur independently of each other. Since most of them are caused by the same inciting agent, in many cases several manifestations, such as "light" and anemia, neurolymphomatosis and lymphomatosis, neurolymphomatosis, and the various types of leukemia, may occur in the same bird. It is pointed out that in some cases of erythroleucosis and lymphomatosis a correct diagnosis can be made only upon histopathological study of the affected tissues. Some birds which do not present symptoms of fowl paralysis show microscopic infiltrations of nerve tissue, but these are not numerous.

The unity of the viruses of leucosis and sarcomatosis of the fowl [trans. title], J. TROISIER and J. SIFFERLEN (*Ann. Inst. Pasteur, 55 (1935), No. 5, pp. 501–517, figs. 6*).—Inoculation experiments indicate that fowl leucosis and sarcomatosis are produced by a single virus.

The isolation of a hemophilic bacillus in pure culture and the reaction of chickens to extranasal inoculations thereof, J. P. DELAPLANE, L. E. EDWIN, and H. O. STUART (*Jour. Agr. Res. [U. S.], 52 (1936), No. 5, pp. 377–383*).—Two phases of a study of hemophilic bacilli conducted at the Rhode Island Experiment Station are reported upon, namely, a technic for isolating *Hemophilus gallinarum* in pure culture, and the reaction of chickens to the extranasal inoculations thereof.

It has been found that *H. gallinarum* may be readily isolated in pure culture from the edematous swellings of fowls showing an infectious coryza, and that the success of the isolation depends on the length of time the swellings have

persisted. It is accomplished by inoculation of sterile chicken blood in a 2-percent sodium citrate solution at the base of nutrient agar slants, preferably within 24 hr. after the swellings have appeared. After 48 hr. there is less chance of obtaining the organism. Since the duration of time the infection has persisted in field cases is usually unknown, it is suggested that for diagnostic purposes susceptible fowls be inoculated intranasally with the infective material and cultures made from them within 24 hr. after the facial swellings are noted. This technic serves as an aid in the differentiation of certain other respiratory infections of fowls in which a coryza is a symptom, particularly that type characterized by a marked rattled breathing and lesions of an acute bronchitis and tracheitis with which a coryza is noted and which may also show some swelling around the eye. The subcutaneous, intraperitoneal, and wattle injections of 24-hr. cultures of *H. gallinarum* failed to stimulate any appreciable immunity, although it was evident that intranasal infection occurred from such inoculations.

"The cloacal inoculation of the cultured organisms combined with laryngotracheitis virus did not result in any upper respiratory infection in a group of five chickens. The chickens were later found to be resistant to laryngotracheitis virus, but susceptible to intranasal inoculations of cultured organisms. The fact that the preliminary group was resistant to intranasal reinoculations remains unexplained."

A comparison of the tube, rapid serum, and rapid blood drop agglutination tests for the detection of carriers of Salmonella pullorum, G. R. SIPE and H. D. POLK (*Mississippi Sta. Bul. 306 (1935), pp. 9, figs. 4*).—Following a review of the subject, presented with a list of 19 references to the literature, experimental work is reported upon.

Comparative tests of the rapid blood drop, rapid serum, and tube methods were found to give very slight variations between the total average positive and negative reactions. There were 31 individual variations between the results of the rapid blood drop and tube, 31 between the rapid serum and tube, and 24 between the rapid blood drop and rapid serum methods. Colored antigen gave a much more conclusive or positive test than clear antigen. The rapid blood drop method was found to be practical and efficient under field conditions and was more economical in time, labor, and money than the tube or rapid serum tests. The rapid blood drop method when applied to the station flock detected five reactors on the first test and no reactors on the second test 6 weeks later. The mortality of chicks from these flocks has been 5 percent with no indications of white diarrhea. In view of the fact that the rapid blood drop method was found to be practical, efficient, and economical, it appears that this method should be given recognition by being placed on a parity with the tube and rapid serum methods, and that it might be recommended to poultry breeders as a reliable, practical method.

The use of pigeon pox virus against fowl pox [trans. title], J. BASSET (*Rev. Vét. [Toulouse], 87 (1935), Oct., pp. 553–559, pl. 1*).—In considering pathogenicity, it is pointed out that even the young of galliform fowl when inoculated with large doses of the pigeon pox virus recover in 2 weeks, while a light form of fowl pox lasts twice that time. It was found that although a small dose of fowl pox virus—very pathogenic for gallines—is sufficient to confer an absolute immunity for a long period of time, 20 times as large a dose of the pigeon pox virus—but slightly pathogenic for gallines—induces only a partial immunity. The work with fowl pox and pigeon pox viruses has shown that the immunity conferred is in direct proportion to the pathogenicity and the dose of the virus employed.

The effect of certain dressings on worm-infested poultry runs, H. F. NEWBIGIN and D. O. MORGAN (*Scot. Jour. Agr., 19 (1936), No. 2, pp. 162–166*).—The experiment reported, in which infested plats 36 × 30 ft. square were treated with (1) agricultural salt 600 lb., (2) ground lime 200 lb., (3) sulfate of ammonia 200 lb., and (4) 50 gal. of 1¾-percent solution of sulfuric acid, respectively, has shown that these treatments are not effective against the eggs of nematodes. It has also shown that heavy infestations with *Heterakis gallinae* and *Capillaria* spp. can take place from runs that have been rested for 8 mo.

Salmonella isolated from baby quail, R. GRAHAM (*Jour. Amer. Vet. Med. Assoc., 88 (1936), No. 6, pp. 763, 764*).—A study of the high mortality in baby quail experienced during the summer of 1935 at one of the Illinois State game farms resulted in the isolation of a *Salmonella* organism which possesses cultural characteristics resembling *S. newport* and, serologically, possesses a group relation to *S. newport*. In this outbreak baby quail that appeared healthy in the evening were found dead the following morning. In some brooders the mortality was as high as 75 percent, and it was estimated that 60 percent of all quail hatched succumbed.

AGRICULTURAL ENGINEERING

The engineering reorganization of farms, N. A. KESSLER (*Agr. Engin., 17 (1936), No. 4, pp. 153, 154, fig. 1*).—This is essentially a brief progress report of studies being conducted by the U. S. D. A. Bureau of Agricultural Engineering in the subject.

[Agricultural engineering investigations by the Massachusetts Station], C. I. GUNNESS, L. A. BRADLEY, J. B. BELKNAP, and C. F. CLANCY (*Massachusetts Sta. Bul. 327 (1936), pp. 8, 9, 22*).—The progress results are briefly presented of investigations on apple storages and stream pollution by private and municipal raw sewage.

[Agricultural engineering investigations by the New Hampshire Station], W. T. ACKERMAN, H. C. MOORE, G. M. FOULKROD, T. B. CHARLES, A. E. TEPPER, F. D. REED, and K. W. WOODWARD (*New Hampshire Sta. Bul. 289 (1936), pp. 20–24*).—The progress results are briefly presented of a rural electrification survey in New Hampshire and of investigations on precooling of milk, heat requirements for brooding chicks, pneumatic tractor equipment, and fence post durability.

[Agricultural engineering investigations by the North Dakota Station], H. F. MCCOLLY (*North Dakota Sta. Bul. 286 (1935), pp. 60–62*).—The progress results are briefly presented of investigations on the ice well and kerosene-burning mechanical refrigerators, and temporary silos.

Surface water supply of the United States, 1934, Parts 5, 6, 9 (*U. S. Geol. Survey, Water-Supply Papers 760 (1936), pp. VIII+250, fig. 1; 761 (1935), pp. IX+340, fig. 1; 764 (1936), pp. VI+151, fig. 1*).—These papers present the results of measurements of flow made on streams during the year ended September 30, 1934, No. 760 covering the Hudson Bay and upper Mississippi River Basins, No. 761 the Missouri River Basin, and No. 764 the Colorado River Basin.

The Thiem method for determining permeability of water-bearing materials and its application to the determination of specific yield, L. K. WENZEL (*U. S. Geol. Survey, Water-Supply Paper 679–A (1936), pp. IV+57, pls. 6, figs. 7*).—This report was prepared in cooperation with the University of Nebraska.

The Thiem method for determining permeability of water-bearing materials consists of pumping a well, or, where the ground water is confined under pressure, allowing the well to flow and observing the decline of the water table or piezometric surface in nearby observation wells. The coefficient of permeability is computed by the formula

$$P=\frac{527.7\,q\log_{10}\frac{a_1}{a}}{m\,(s-s_1)}$$

where P is the coefficient of permeability, q the rate of pumping in gallons a minute, a and a_1 respective distances of two observation wells from the pumped well in feet, m for artesian conditions the vertical thickness of the water-bearing bed in feet, m for water-table conditions the average vertical thickness at a_1 and a of the saturated part of the water-bearing bed in feet, and s and s_1 the draw-downs at the two observation wells in feet. This formula is mathematically developed by assuming ideal geologic and ground water conditions, such as a uniform permeability, a uniform thickness of water-bearing bed, a horizontal water table or piezometric surface, and a cone of depression that has reached equilibrium in form. As these conditions are rarely approached, the applicability of the formula and hence of the method has been regarded as questionable.

Two rather elaborate pumping tests were made in 1931 near Grand Island, Nebr., in which the behavior of the ground water was observed over a large area around the pumped wells by measuring the fluctuation of the water table in 81 observation wells during the period of pumping and after pumping was stopped. A study of the data obtained from these tests indicates that the Thiem method is applicable to conditions that are found in nature, but to obtain consistent and accurate determinations of permeability it is necessary to employ an arbitrary procedure in computing the coefficient. The draw-down of the water table at any distance from the discharging well should be taken as the average of the draw-down at that distance up-gradient and down-gradient from the well. In the first test described in this report the cone of depression reached approximate equilibrium in form out to about 200 ft. from the pumped well after 48 hr. of pumping and was affected by irregular conditions near the well as far as 40 ft. from the well. Hence the draw-downs that were used for computations of permeability were selected from that part of the cone between 40 to 200 ft. from the pumped well. In the second test pumping was stopped several times and the cone of depression did not reach approximate equilibrium in form.

Computations were made to determine the specific yield of the water-bearing materials from the data obtained in the pumping tests. The results show that the specific yield can be readily determined by this method. Samples of the material were analyzed in the laboratory for specific yield, and the results obtained compared favorably with those determined by the pumping method.

Readjusting Montana's agriculture.—VI, Montana's irrigation resources, P. L. SLAGSVOLD (*Montana Sta. Bul. 315 (1936), pp. 18, figs. 4*).—This bulletin presents an inventory and analysis of the irrigation water resources of Montana in relation to agricultural adjustment in the State. It is pointed out that at present the irrigated area embraces about 2,000,000 acres of land scattered throughout the entire State. Much of this land is watered from seepage or from occasional floods, which makes it suitable only for hay. A large proportion of the remainder is subject to periodic or occasional water shortage, which prevents development of intensive farming. Without supplementary storage,

much of the land cannot be put to its best use. The available water in readily accessible streams has been appropriated by private users or companies. In many cases these rights to water are distributed in such a way as to cause a wasteful and often detrimental use. Some areas could solve their water problem best by pooling the rights and making a complete change in the distribution system. Other areas need storage.

Where large irrigation works have to be constructed, either for new or supplemental development, the problems of costs, returns, and financing are significant, as are also the questions of the best method of assessing the costs in accordance with benefits received. Montana at present has no law which provides for spreading the burden of irrigation developments over the entire community.

The belief is expressed that much of the irrigation development in Montana in the next few years probably will take the form of greater intensification in the use of existing irrigated land, either through the development of supplemental water on major irrigation projects, reviving defunct irrigation districts and companies, or more intensive agriculture on a few large irrigated stock ranches.

Farm irrigation pumping plants, A. S. CURRY (*New Mexico Sta. Bul. 237 (1936), pp. 44, figs. 21*).—Technical information of a generally practical character is presented on the development and sinking of wells for farming irrigation pumping and the selection and installation of pumping plants and necessary equipment. An appendix gives the text of the New Mexico law relating to underground water.

The Parshall measuring flume, R. L. PARSHALL (*Colorado Sta. Bul. 423 (1936), pp. 84, figs. 30*).—A description is given of this flume, together with the results of laboratory and service tests and tabular discharge data.

The Parshall measuring flume has shown in field operation that it is practical under conditions which make a standard weir or rating flume impractical, either because of silting trouble or insufficient grade. As to the accuracy of measurement with this device, the observed discharge, free flow, was within 3 percent of the computed amount in 89 percent of the tests, while for the submerged flow, 85 percent of the observed discharges were within 5 percent of the computed amounts. The range of capacity of discharge from a minimum of less than 0.1 sec.-ft. through the 3-in. flume to a maximum of 1,500 sec.-ft. through the 40-ft. flume, as limited by present investigations, is sufficient to meet ordinary requirements. This device operates successfully with relatively small loss of head, and for free flow this loss in a standard weir is approximately four times that in the flume. The flume will withstand a high degree of submergence without affecting the rate of free-flow discharge, and for this reason it is recommended that the throat-gage stilling well be provided to obtain the full efficiency of the flume. Because of the increased velocity of the water it will operate successfully in sand- or silt-laden streams. Since the floor of the structure is constantly swept clean of all deposit, constancy of condition is maintained.

Operation is simple because it has no adjustable or moving parts. Its dimensions are not easily altered so as to cause wilfully unfair measurement of the discharge. The filling of the weir box upstream from the crest, by natural deposit from the stream, causes the weir to over-register, and consequently there is no incentive on the part of the water user to correct this condition. Discharge through rating flumes may be changed to the advantage of the user by altering downstream conditions. Velocity of approach of the stream to the entrance of this device has little or no effect upon the rate of

discharge. Plane surfaces in the structure make it easy to construct. For moderately large flows the upper ends of the converging section should be rounded off by means of sheet metal pieces rolled to a radius of 4 or 5 ft. The structure may be built of wood, concrete, or sheet metal. Precast concrete members may be made and assembled in the field for the small-sized flumes. Sheet metal flumes, portable because of their light weight, are entirely practical for the small sizes.

Recording instruments may be operated in connection with this device to register heads or total discharge. Where the degree of submergence exceeds about 95 percent, the indicated discharge through the flume is not wholly dependable. If conditions permit, the discharge should be free flow or with the least possible degree of submergence. For free flow, the flume's measurement of discharge depends upon a single head or depth only, it being similar in this respect to a standard weir or rating flume. The upper head in the converging section, or the throat head, may be read on either side of the flume with equal accuracy. Scales or gages attached to the inside of the flume for the purpose of determining the head are not recommended except for small flows or moderate depth and free-flow condition. Better results are obtained if the heads are observed in stilling wells outside the structure. For free flow the exit velocity is relatively high, and bottom as well as bank protection must be provided to prevent erosion. Where the materials are of such a nature as to withstand a high velocity, such as heavy gravel or rock, no attention need be given to protection.

The Parshall measuring flume has the advantage over the old type of Venturi flume in that the angles of convergence and divergence are such as to eliminate the effect of the switching of the current in the diverging section, which, in the old flume, affected the discharge.

Public Roads, [April, May, and June 1936], (*U. S. Dept. Agr., Public Roads, 17 (1936), Nos. 2, pp. 21–43+[1], figs. 21; 3, pp. 45–68+[1], figs. 23; 4, pp. 69–88+[2], figs. 17*).—These numbers of this periodical contain data on the status of the various highway projects, receiving Federal funds, as of March 31, April 30, and May 31, 1936, respectively, and the following articles:

No. 2.—The New Hampshire Financial Survey, by E. Church (pp. 21–37, 40), and Dimensions of Testing Equipment Affect Hubbard-Field Stability Values, by J. T. Pauls (pp. 38–40).

No. 3.—Stabilized Soil Roads, by C. A. Hogentogler and E. A. Willis (pp. 45–65).

No. 4.—Circular Track Tests on Low-Cost Bituminous Mixtures, by C. A. Carpenter and J. F. Goode (pp. 69–82), and Indexes of Highway Construction Costs (pp. 83–85).

Loaded spoked vehicle wheels, J. B. Reynolds and F. L. Ehasz (*Agr. Engin., 17 (1936), No. 4, pp. 155–161, figs. 5*).—In this contribution from Lehigh University the fundamental formulas upon which the analysis of loaded spoked wheels is based are presented, together with an exposition of the manner of their use.

Additional formulas for rim, spoke, and center deflections applicable for the two critical positions are derived. Detailed applications of the general theory to a 4- and 6-spoked wheel for the first position have been worked out, and the former are presented. The method for any number of spokes is outlined. Simplified solutions for both critical positions are given for 4 and 6 spokes and indicated for any number. Finally, experimental checks on the theory made by the photoelastic method are presented.

The mathematical theory of elasticity is utilized in developing general and simplified methods of analysis for vehicular wheels with an even number of

spokes. Critical rim and spoke moments are developed with the two lowest spokes of the wheel assuming an equal angle with the vertical. When two spokes are vertical, the lower spoke takes over 90 percent of the load. It is desirable, therefore, to design spokes so that they will carry the entire load in this position. Contrary to the opinion of a former investigator, both the analytical and photoelastic results confirm the fact that the two lower spokes of the 4-spoked wheel, with spokes at 45°, develop higher stresses than the upper spokes. The upper half of the 6-spoked wheel in both critical positions had relatively small stresses. Although there was some lack of agreement between the analytical and experimental results, the critical conditions which are most important from the practical viewpoint were approximately similar, with the analytical solution practically always on the safer side.

It is felt that the graphical method of analyzing stresses in this problem leads to erroneous results. The present investigation takes into account the elasticity of straight and curved rods, and as a consequence approaches actual stress conditions more closely.

A nursery thresher for sorghum heads, R. O. SNILLING (*Jour. Amer. Soc. Agron., 28 (1936), No. 3, pp. 253, 254, fig. 1*).—A nursery thresher particularly adapted to individual heads of sorghum, constructed at the U. S. D. A. Dry Land Field Station, Lawton, Okla., is described and illustrated.

The vertical drier for seed cotton, C. A. BENNETT and F. L. GERDES (*U. S. Dept. Agr., Misc. Pub. 239 (1936), pp. 22, figs. 16*).—This publication supersedes Miscellaneous Publication 149 (E. S. R., 68, p. 106). It describes the vertical drier for seed cotton developed by the Bureau of Agricultural Engineering for carrying out the Government process of artificially drying seed cotton.

In this drier the drying chamber contains no moving parts, and the seed cotton is carried through it by the blast of drying air. Because of the simplicity of this design it is more economical to construct and to operate than the earlier types. Moreover, to an appreciable degree this type automatically adjusts the period of exposure in the drying chamber to the degree of dampness of the cotton, because that which has little moisture moves through the chamber more quickly than that which has much moisture. This drier has proved satisfactory in actual service under wide variations in conditions.

Very wet cotton can be dried by passing it through the drier a second time. The apparatus will condition seed cotton for ginning in any kind of weather, provided the dried cotton is conveyed from the drier directly to the gins in the heated air.

Information on installation and operation is included.

Burr mill design and performance, H. D. BRUHN (*Agr. Engin., 17 (1936), No. 3, pp. 101–107, figs. 18*).—Studies conducted at the Wisconsin Experiment Station are reported, the purpose of which was to determine some of the fundamental principles involved in the design and performance of the burr type feed mill and the relation of the numerous factors to each other. Data from over 600 tests conducted over a period of 3 yr. are summarized.

It was found that to obtain high grinding efficiency in the small burr type mills, the speed must be high and the rate of feeding must be regulated to eliminate crowding of the burrs. Therefore it is necessary that the mill be equipped with a feeding device which will continue to feed the mill uniformly at any desired rate.

When high speeds are used it is necessary to use rigid burr mountings, good bearings (preferably antifriction), and fixed burr clearance to eliminate vibration and to prolong the life of the burrs and the mill. It is also essential that the mill be equipped with a safety release to obviate damage due to foreign material in the grain.

The permissible rate of feeding the mill is almost directly proportional to the speed. Therefore, when the most efficient rate of grinding at any speed is found for a particular burr, it is possible to predict very closely the most desirable rate of grinding for any other speed or to predict the proper speed for any other rate of grinding desired.

A burr mill, if operated at fairly constant speed and rate of feeding, will grind to nearly the same fineness modulus for a long period of time at a given burr clearance. Burr design is a very important factor in the performance of a mill. It has been demonstrated that in the small size the burr mill will perform equally as well as the hammer mill.

New Jersey laying houses, E. R. GROSS (*New Jersey Stas. Hints to Poultrymen, 23 (1936), No. 4, pp. 4*).—Practical information is given on poultry house planning and construction for New Jersey conditions, including data on lighting, wall and floor construction, insulation, and ventilation.

AGRICULTURAL ECONOMICS

[Papers presented at the twenty-sixth annual meeting of the American Farm Economic Association] (*Jour. Farm Econ., 18 (1936), No. 2, pp. 229–420, figs. 2*).—Papers with discussions thereon, in addition to those previously noted (E. S. R., 75, p. 268), are included as follows: The Agricultural Adjustment Act and National Recovery, by C. C. Davis, with discussion by J. D. Black (pp. 229–243); Fundamental Significance of the Agricultural Adjustment Concept, by E. G. Nourse, with discussion by J. I. Falconer (pp. 244–256); The Social and Economic Implications of the National Land Program, by L. C. Gray, with discussion by N. Clark(pp. 257–280); A Future Pattern of Research in Agricultural Economics, by E. Englund, with discussion by F. F. Hill (pp. 281–295); Research in Agricultural Economics From the Standpoint of the States, by T. W. Schultz, with discussion by F. P. Weaver (pp. 296–310); Agricultural Policy and the Economist, by A. G. Black (pp. 311–319); A Classification and Summary of Research Projects in Dairy Marketing, by S. C. Hudson (pp. 320–329); Research in the Consumption and Demand for Milk, by W. C. Waite (pp. 330–337); Research in Costs of Distributing Milk, by L. Spencer (pp. 338–351); Transportation of Milk in the St. Louis Milkshed, by R. W. Bartlett (pp. 352–362); Marketing Research Needs of the Dairy Industry, by H. A. Ross (pp. 363–368); Research in Marketing Fruits and Vegetables, by N. L. Allen (pp. 369–371); The Motor Truck in Relation to Fruit and Vegetable Marketing, by M. P. Rasmussen, with discussion by H. H. Bakken (pp. 372–387); New York Foods Consumption Survey, by A. Sturges, with discussion by E. R. French (pp. 388–392); Research as a Basis for Grading Fruits and Vegetables, by C. W. Hauck, with discussion by W. G. Meal (pp. 393–404); and Urgent Needs for Research in Marketing Fruits and Vegetables, by F. V. Waugh, with discussion by W. C. Hopper (pp. 405–420).

[Notes on agricultural economics] (*Jour. Farm Econ., 18 (1936), No. 2, pp. 421–430*).—Included are California Agricultural Prorate Act Constitutional, by E. A. Stokdyk; Can Counties be Reorganized—Consolidated?, by H. L. Euler; Results of the Czechoslovakian Land Reform, by S. Borodaewsky; and Developments Affecting the International Trade of the United States in Agricultural Products, by J. D. Black.

[Investigations in agricultural economics by the Massachusetts Station, 1935] (*Massachusetts Sta. Bul. 327 (1936), pp. 5–8*).—Included are (1) a brief summarization of conditions as to rural real estate tax delinquency, tax sales, redemption, etc., during the period 1928–32, found by R. L. Mighell in a study

made in cooperation with the Bureau of Agricultural Economics, U. S. D. A., and (2) a few facts as to municipal control of milk in New Zealand and two small areas in the United States, found by Mighell in a study of milk as a municipal utility.

[Investigations in agricultural economics by the New Hampshire Station, 1935] (*New Hampshire Sta. Bul. 289 (1936), pp. 8–10*).—Included are (1) a table showing the receipts from agricultural products, forest products, outside work, and pensions, gifts, etc., on 255 southern Grafton County farms, as found in a study of land utilization by H. C. Woodworth and M. F. Abell; (2) data by L. A. Dougherty as to grading percentages on over 11,000 cases of large brown eggs handled by the New Hampshire Auction during its first year; and (3) some results of the type of farming area study made in cooperation with the U. S. D. A. Agricultural Adjustment Administration by H. C. Grinnell, Woodworth, E. H. Rinear, Dougherty, and A. J. Hangas.

[Investigations in agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Bul. 180 (1936), pp. 80, 81*).—The table of index numbers of production, prices, and income by J. I. Falconer (E. S. R., 75, p. 269) is brought down through February 1936. A table by Falconer shows by years 1929–35 the estimated tons of different commercial feeds reaching the retail trade in Ohio.

[Investigations in agricultural economics by the Wisconsin Station, 1934–35] (*Wisconsin Sta. Bul. 435 (1936), pp. 134–144, figs. 3*).—Included are (1) chart, table, and text showing the average retail margins on different kinds of cheese, as found by M. A. Schaars in a study of 74 independent stores throughout the United States; (2) a table and other data by Schaars comparing the rail and truck costs in shipping hogs; (3) some data as to the value of and kinds of commodities purchased in 1934 through farmers' cooperative purchasing associations, as found in a study of such associations by R. K. Froker, M. A. Abrahamsen, W. F. Finner, and J. G. Knapp; (4) a table by H. H. Bakken showing the production costs—raw material, direct operating, marketing, and administration—and the selling price per case of 48 cans of condensed and evaporated milk by years 1929–32, as found in a study of two large Wisconsin plants; (5) a chart showing the annual State, county, and local direct tax levies for school support, 1921–35, in a typical low property value county, as found in a study of the distribution of State aids by B. H. Hibbard and K. H. Parsons; and (6) a map dividing the State into six type-of-farming regions and 15 type-of-farming areas, and a table showing the percentages of crop land in each region intertilled, in small grain, and in hay in 1929, as determined in a study made by the station, the Wisconsin Crop and Livestock Reporting Service, and the U. S. D. A. Agricultural Adjustment Administration and Bureau of Agricultural Economics.

Income parity for agriculture, L. H. Bean (*U. S. Dept. Agr., Agr. Adjust. Admin., 1936, pp. [15], figs. 3*).—This is "a brief discussion of (a) price or income as a standard for agricultural recovery, (b) a measure of income parity, and (c) the ratio of the purchasing power of net income per person on farms and the purchasing power of income per person not on farms."

Western land policies and recent ownership trends, R. R. Renne (*Jour. Land and Pub. Util. Econ., 12 (1936), No. 1, pp. 33–43, figs. 5*).—This in a contribution from the Montana Experiment Station. Maps and a table are included and discussed, showing the total percentages in 1934 of the total land area of the State owned by the Federal Government, the State, counties, miscellaneous public agencies, railroads, investment and mortgage companies, lending agencies (commercial banks, insurance companies, Federal Land Banks, and joint stock land banks), miscellaneous corporations, individuals resident in the State,

and individuals nonresident in the State. The changes from 1925 to 1934, the causes for the changes, and the possible methods for correcting the present maladjustments are discussed.

Rural real estate tax delinquency in New Hampshire, H. C. GRINNELL (*New Hampshire Sta. Bul. 290 (1936), pp. 19*).—This bulletin presents a general summary of the data collected in New Hampshire for the period 1928–33 in cooperation with the Bureau of Agricultural Economics, U. S. D. A. The irregularities in the local tax collection practices are discussed. Analysis is made of the extent and trends in tax delinquency 1928–32 and the extent of tax sales, their relation to delinquency, and tax sale redemptions 1929–32.

Tax advertisements nearly doubled from 1928 to 1931 and then declined in 1932 due to a lower average tax rate. More than 75 percent of the delinquent properties were classed as farm land with buildings. Two-thirds of the advertisements for the 1931 levy went to sale in 1932 as compared with about 56 percent for other years. The value of tax sales in 1932 was 232 percent of that in 1929, indicating that sales were increasing faster than advertisements and that a smaller percentage was being discharged before sale.

"Much of the tax delinquency and sale of rural real estate was of short duration, being repeatedly delinquent or sold for more than one year, but only for one year at a time. Thus the increase in each year's delinquency or sales over the previous year's figures are of major importance in that they more nearly represent a new delinquency and indicate the increasing burden of property taxes on rural people. . . .

"The officials of many towns have been found to be negligent in the administration of tax laws. Irregularities in local practices with respect to the collection of taxes, more particularly those concerned with the advertisement and sale of delinquent properties, affect the comparability of the data assembled for this project."

The production credit system of 1933, J. K. GALBRAITH and J. D. BLACK (*Amer. Econ. Rev., 26 (1936), No. 2, pp. 235–247*).—"This paper describes briefly the structure of the system and outlines the scale of loaning operations to date. At the end of 1934 it seems probable that the system had approximately one-tenth as many loans outstanding for agricultural purposes as did the commercial banks. The competitive position of the system, particularly in relation to country banks, is discussed in some detail. Attention is also given to the perplexing problem which the system faces in its efforts to maintain a uniform loan rate for all parts of the country."

Agricultural labor in the United States, 1915–1935, compiled by E. M. COLVIN and J. C. FOLSOM (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 64 (1935), pp. VII+493*).—This mimeographed bibliography includes 1,746 selected annotated references grouped under the following headings: General agricultural labor, agricultural ladder, child labor, contract labor, cost and standard of living, efficiency, employment and unemployment, employment agencies and services, farm laborers' allotments, hired man, history, hours of labor, immigrant labor, insurance, labor displacement, labor management, labor unions, legislation, migration to cities, migratory labor, mobility, occupational hazards, overtime pay, profit sharing, sharecroppers, statistics, strikes and labor unrest, supply and demand, training, wages and perquisites, women as agricultural laborers, and workmen's compensation.

An economic study of hog production and marketing in South Carolina, M. GUIN (*South Carolina Sta. Bul. 305 (1936), pp. 27, figs. 9*).—The purposes of this study were to ascertain the present cooperative position of the hog enterprise in South Carolina and its relation to crop enterprises, other livestock

enterprises, and other corn-hog producing areas of the United States; to determine the economic influences of the AAA corn-hog production program upon corn-hog production in South Carolina especially in regard to the parts of the State in which reduction took place and the crops planted on land taken out of corn; and to determine the prospective status of the hog enterprise in the State. The author concludes as follows:

"While swine production is responsive to a number of influences, the corn enterprise is the dominant influence. The yearly changes in corn acreage in South Carolina give a good explanation of the annual changes in number of hogs on farms on January 1 of the following year. Corn acreage is greatly affected by changes in cotton acreage. When cotton acreage is increased, corn acreage is decreased, and vice versa. Crops other than cotton have only a small effect on corn acreage and hog production.

"The AAA corn-hog program in South Carolina did not have a great influence on hog production. This was due largely to the fact that South Carolina is a deficit corn and hog producing State. More farmers would have signed corn-hog contracts in 1934 had they cared to reduce corn acreage. Most of the farmers do not produce enough corn for home consumption. Forage crops were the usual crops grown on the land taken out of corn production in 1934.

"With the use of more home-grown feed, the hog enterprise is likely to increase slowly during the next several years in South Carolina, at least to the extent of supplying home needs for pork. A number of the present disadvantages of hog production can be overcome."

An economic study of poultry farming in Virginia, J. L. MAXTON (*Virginia Sta. Bul. 300 (1936), pp. 58, figs. 10*).—Data were collected by the survey method from 164 farms in 1931 and 213 farms in 1932. The farms in 1931 ranged from 1 to 700 acres in size, averaging 112 acres, with an average of 37 acres of crops. The poultry flocks ranged from 235 to 2,596 birds, averaging 737. In 1932 the farms ranged from 1 to 550 acres in size, averaging 108 acres, with an average of 42 acres in crops. The flocks ranged from 159 to 2,962 birds, averaging 656. Analysis is made of the farm capital, receipts from poultry crops, dairy products, livestock and miscellaneous services, expenses, etc.; of the feed, man labor, horse work, and other costs in producing eggs, hatching chicks, and raising pullets; of the returns from eggs; and of the factors affecting labor income on poultry farms. The production per hen necessary to pay for feed, profitable poultry practices, the markets for poultry and eggs, and the outlook for poultry and egg production in Virginia are discussed.

The average capital investment for the farms studied was $13,124 in 1931 and $12,299 in 1932. The average net cost of producing eggs was 25.2 ct. per dozen in 1931 and 20.8 ct. per dozen in 1932. Labor incomes averaged $280 in 1931 and $56 in 1932.

Higher than average number of hens, better than average hens, increased labor efficiency, increased feeding efficiency, low mortality in flocks, and high egg production in the fall months gave lower than average cost of producing eggs. Early hatching of chicks, maintenance of good body weight of layers by proper feeding, year-round feeding of some form of milk and green feed, and a high quality of hens resulted in a high egg production per hen. In general, there was a close correlation between low cost of egg production and high labor income. Farmers selling baby chicks, pullets, breeders, and broilers in addition to eggs were generally more successful than those specializing in intensive egg production.

Egg production, monthly costs, and receipts on New Jersey poultry farms, November 1934–October 1935, L. M. BLACK and J. C. TAYLOR (*New Jersey Stas. Hints to Poultrymen, 23 (1936), No. 2, pp. 4*).—This is a summary of detailed costs of egg production compiled from the records of 21 cooperators representative of all sections of the State and including flocks of various sizes.

Seasonal costs and returns in producing milk in Orange County, New York, L. C. CUNNINGHAM ([*New York*] *Cornell Sta. Bul. 641 (1936), pp. 41, figs. 7*).—Detailed records relative to farm receipts, expenses, inventories, cropping systems, and other farm practices, with special reference to the seasonal costs and returns in producing milk, were obtained from 111 dairy farmers for the year ended April 30, 1931. The area and the farms studied are discussed. Analysis is made of the yearly costs and returns in producing milk and the effects of costs per 100 lb. of milk, rates of production, size of herd, labor efficiency, and other factors on the costs and returns. Some analysis is also made of seasonal and monthly costs.

The average capital per farm was $16,000. Labor income averaged $270 per farm. About 40 percent of the farmers showed losses, but 10 percent had labor incomes of $2,000 or more. Cost of feed constituted 52.1 percent of the total yearly costs of milk production, man labor 26.3, and depreciation 9.3 percent. No other item of the 10 studied amounted to as much as 5 percent. The average net cost of producing milk was $2.70 per hundredweight and the average price received $2.72 per hundredweight. The average return to labor from the cow enterprise was 30.5 ct. per hour. The net cost per hundredweight of milk fluctuated from 67 percent of the yearly average in June to 117 percent in April. Rate of milk production was the most important factor affecting costs and returns. Feeding practices and season of production had a decided effect on milk production per cow. Large-sized herds made possible low unit cost of production. In general, the highest incomes were obtained by dairymen who kept good cows and a sufficient number of cows to use the available labor force efficiently.

Analysis of open commitments in wheat and corn futures on the Chicago Board of Trade, September 29, 1934, D. B. BAGNELL (*U. S. Dept. Agr. Circ. 397 (1936), pp. 20, figs. 8*).—Examination was made of the records of 111 clearing firms and 507 nonclearing commission firms, and information was obtained by correspondence from three domestic and 11 foreign firms. Analysis is made of the number of accounts and volume of open commitments, distribution of accounts and open commitments between speculators and hedgers, size of accounts, and geographic distribution and occupation of traders.

At the close of business September 29, 1934, 18,364 individuals, firms, and corporations held future contracts in wheat or corn or both on the Chicago Board of Trade. Of the 13,194 wheat accounts, 88 percent were speculative. Of the 8,089 corn contracts, 89 percent were speculative. Approximately 48 percent of those in wheat were for less than 5,000 bu. and 92 percent for less than 25,000 bu. Forty-seven percent of the long speculative accounts in corn held less than 5,000 bu. and 91 percent less than 25,000 bu. Speculators held 75 percent of the long contracts in wheat and 74 percent of those in corn. Hedgers held 82 percent and 79 percent, respectively, of the short interest. Every State in the United States was represented in the accounts but nearly 90 percent originated in the 18 States located mainly in the grain-growing area of the Middle West. There was a considerable participation from Canada, Europe, and the Orient. The larger occupational groups having accounts were farmers, who had 1,492 contracts in wheat and 1,047 contracts in corn, and housewives with 802 contracts in wheat and 496 contracts in corn.

"The hedging burden was about equally divided between two groups, one consisting of farmers, clerks, small merchants, and others of apparently limited means, and the other made up of professional traders, executives, financiers, and the like.

"Information obtained by the Administration as the result of special studies, surveys, and investigations shows conclusively that the small speculators play a most important part in the merchandising of the Nation's grain. They are nearly always on the long side, in contrast to the large professional traders who are as likely to be sellers as purchasers. If not subjected to periodic 'shaking-out' processes, these small traders would doubtless be an even more dependable group of hedge carriers."

The production-consumption balance of agricultural products in Michigan.—Part 2, Livestock and animal products, G. N. MOTTS (*Michigan Sta. Spec. Bul. 269 (1936), pp. 40, figs. 10*).—This is the second bulletin in the series previously noted (E. S. R., 74, p. 558). Charts and explanatory text show the production in the State, shipments to and from other States, and estimated consumption or utilization in the State, the figures used being the averages for the following years: Livestock and meats, 1928–32; wool, 1932–33; and dairy products and poultry and eggs, 1929–33.

The ratios of production in the State to the consumption within the State were found to be as follows: Beef 45 percent, veal 134, pork 45, lamb and mutton 124, wool 480, milk and cream 101, butter 100, cheese 69, condensed and evaporated milk 166, dried and powdered milk 171, poultry 59, and eggs 78 percent. The percentages of State consumption from the Michigan production were beef 40, veal 75, pork 35, lamb and mutton 50, wool 24, milk and cream 99.3, butter 17.4 to 17.8, cheese 41, poultry 57, and eggs 70 percent.

A study of the demand for potatoes in the Twin Cities, L. F. GARREY (*Minnesota Sta. Bul. 324 (1935), pp. 24, fig. 1*).—This study is based on data obtained during March and April 1935 from 1,356 retail stores, 20 hotels, 128 restaurants and cafeterias, and 21 hospitals in Minneapolis and St. Paul, Minn. About 43 percent (959,410 bu.) of the consumption of potatoes in the two cities was covered. Analysis is made for the stores of the kinds and quantities of potatoes sold in the different types of stores, methods of sale, unit of sale, source and frequency of purchase, grades purchased, the relation of income of consumers to kind of potatoes used and prices paid, etc. For the hotels, eating places, and hospitals analysis is made of the kinds and quantities of potatoes used, prices paid, size preferences, methods of cooking, sources of purchase, etc. The objections made to Minnesota potatoes are also analyzed.

About 30 percent of the potatoes used in the two cities were grown outside the State. About 50 percent of the objections to Minnesota potatoes were on the grounds of disease, poor quality, and lack of uniformity. There was found to be a considerable demand for the very best quality of potatoes, and the large proportion of russet potatoes from the western States used indicates that Minnesota-grown potatoes do not possess all the qualities required by this rather select trade.

Ninety percent of the potatoes shipped out of Minnesota were found to go to 20 cities, chiefly southeast of the State, where the State was at some disadvantage in competing with Wisconsin and Michigan potatoes. This disadvantage, however, could be offset, the author believes, by producing and marketing potatoes of a higher quality and greater uniformity.

World consumption of wool, 1928–35 (*London: Imp. Econ. Com., 1936, pp. 306, [pls.] 9*).—This is an analysis of the consumption and trade in wool and wool products in the British Empire and other countries of the world.

"The plan adopted for each country has been to open with a brief introductory paragraph, followed by a statement of the machine equipment and labor supply; then to estimate from trade and wool production statistics the available supplies of raw wool; to summarize the available information on production and trade in semimanufactures; and to conclude with the output and trade in finished goods—more particularly clothing tissues. The hosiery and carpet industries have been included only where their consumption of wool is sufficiently high to render them a factor of major importance. The highly complicated and technical nature of tariff and quota regulations preclude any but the briefest references."

A chapter (pp. 258–293) discusses the prices of raw wool, wool rags, semimanufactures, and tissues.

Crops and Markets, [April–May 1936] (*U. S. Dept. Agr., Crops and Markets, 13 (1936), Nos. 4, pp. 113–144, figs. 3; 5, pp. 145–176, figs. 3*).—Included are tables, reports, summaries, charts, etc., of the usual type. No. 5 also includes tables showing by States and by years 1920, 1925, and 1930–36, inclusive, the estimated value per acre of farm real estate on March 1 in terms of pre-war average (1912–14) value.

RURAL SOCIOLOGY

[Investigations in rural sociology by the Wisconsin Station, 1934–35] (*Wisconsin Sta. Bul. 435 (1936), pp. 145–150*).—Included are (1) a brief statement of findings as to the occupation and earnings of young people in a study in Wood and Waushara Counties by E. L. Kirkpatrick; (2) data regarding the reasons for households receiving relief and the rehabilitation possibilities and needs of the relief households, as shown by a study by Kirkpatrick in cooperation with the Rural Resettlement Administration in the Central Wisconsin Nesting and Phelps-Crandon areas of Wisconsin submarginal land purchase tracts; (3) findings as to the cost of living of farm, nonfarm, open country, and village groups in the Forest County section of the Crandon land purchase area, in a study of 290 families, by Kirkpatrick, A. Mucks, and M. L. Cowles; and (4) data as to the changes in the number of rural families receiving relief in 1934 and 1935 and the types of households—farm, owner-operator, tenant, and nonagricultural.

The libraries of Missouri: A survey of facilities, E. L. Morgan and M. W. Sneed (*Missouri Sta. Res. Bul. 236 (1936), pp. 94, figs. 17*).—"This is a statistical study of the library facilities in Missouri. The location and resources of all public libraries and for most of the other types are analyzed and compared. Particular consideration is given to the comparative distribution of libraries and to the services they render rural as compared with urban population. Here, it is indicated that more than one and one-half million people in Missouri, most of them rural, are not served by public libraries. While revenue for maintenance has declined during the past 5 yr., the total book circulation has materially increased in all classes of libraries."

Farm versus village living in Utah, [II], J. A. Geddes (*Utah Sta. Bul. 269 (1936), pp. 82, figs. 30*).—This, the second of a series of three publications dealing with conditions found in Plain City (E. S. R., 72, p. 127), deals with the use of local community agencies and institutions and of outside community offerings in neighboring towns and cities.

Among other findings, it is concluded that "education increases community participation up to and including completion of high school. . . . There is no evidence that increasing education brings improved balance in the selec-

tion of offerings in the various fields of living. The fields that are emphasized by the well-educated as well as by the uneducated are: Education, recreation, religion, and vocation. Neglected fields pertain to culture, government, family life, and health. . . .

"Community participation increases from 6 to 18 yr. of age where it reaches a high point at 18. After 21 a rapid decline occurs. From 24 to 30 a slight decline continues. Between 30 and 44 up-and-down movements take place, but with little comparative gain or loss. From the 44th to the 59th years attendance increases. After 59, participation definitely declines. If, however, schools and recreation are eliminated, the golden age of community participation lies not alone in youth but also in the 10-yr. period from 50 to 59 yr. and extending on a level above the average up to the 64th year. With advancing age, the two village-farm groups maintain a higher community participation average than do the farm-dweller and nonfarm groups. Community-mindedness continues with advancing age to show greater strength within the village."

Forces affecting participation of farm people in rural organization, D. E. LINDSTROM (*Illinois Sta. Bul. 423 (1936), pp. 77–127, figs. 19*).—This study was undertaken to gain an accurate estimate of the social forces affecting the participation of farm people in rural organization in 4 rural townships in central Illinois. The 250 households studied included 975 individuals, averaging 3.9 persons per household. Eighty-seven percent of the total number were of native parentage. Slightly more than half had less than an eighth-grade education.

About one-fourth of the heads of households were owners or part owners of farms, two-thirds were tenants, and one-sixth were farm laborers. The average farm operator spent more than nine-tenths of his time on the farm, and he and all members of his family of productive age were normally at work on the farm more than one-third of the time. They spent one-fourth of their time in rest and recreation, which left slightly more than one-third of the time for sleep. More off-the-farm time was spent in trading than for any other one purpose.

The farmers in this study normally shipped their livestock through farmer-owned associations or by truck to large marketing centers, such as Chicago or St. Louis. Their grain was delivered to the village or to the country elevators. Most of them patronized local banks.

Voluntary organizations drew their support mainly from the most stable members of the communities. Participation went hand in hand with the development of leaders. All leaders were expected to have such personal qualities as friendliness, honesty, courage, industry, perseverance, faithfulness, and ability to plan.

Rural youth: Activities, interests, and problems.—I, Married young men and women, 15 to 29 years of age, W. A. ANDERSON ([*New York*] *Cornell Sta. Bul. 649 (1936), pp. 55, fig. 1*).—This is a report of the results of a survey conducted by the Tompkins County Development Association to reveal the needs of the rural young people in that county. It shows what married young people are doing and what they would like to do. The facts reported challenge the attention of rural organizations and agencies concerning their responsibility for giving larger services to those who are starting rural homes. They also indicate the importance of such information as the basis for planning programs of work by rural organizations and the desirability of ascertaining similar information by local groups in other counties.

The activities, interests, and problems of 347 married young men and [redacted] who live in the open country and villages of Tompkins County [redacted]

One-third of those interviewed were men and two-thirds were women. Their average ages were 28 and 24 yr., respectively. Most of them had resided 5 yr. or more in rural environments. Of the group, 30 percent lived on farms, 40 percent in villages, and 30 percent were open-country, nonfarm residents.

The schooling of these young people averaged more than 2 yr. of high school. Their occupational backgrounds were farming, skilled work, and unskilled labor. At the time of the study 81 percent of the young men were employed full time at remunerative occupations, 11 percent were employed part time, and 4 percent were unemployed. Of the young women, 86 percent were engaged in housework, 8 percent were gainfully employed all the time, and 5 percent had part-time work. Of the young men, 95 percent had persons dependent upon them. All but 5 percent were responsible, wholly or in part, for the care of other people. Only 3 percent of the young women had others dependent upon them.

Of the young men, 82 percent, and of the young women, 67 percent had received no organized training for any vocation.

Need for occupational guidance and training is emphasized by the number of young men who would like to change their vocations. Leisure time activities engaged in most frequently by both men and women were the indoor, passive type, including reading, card playing, checkers, chess, and other games, and listening to the radio. Outside activities were second in importance, while household activities were third. Hobbies and outdoor sports ranked fourth in importance.

The home was the main center of activities, while schools, churches, and other institutions were used only occasionally for recreation. Of the young men, 56 percent, and of the young women, 48 percent had 2 hr. or less per day for leisure activity. In the leisure program, reading is of major importance to young men and women. Magazines were read in 9 of each 10 of the homes, many of them being of the sensational type. Books were much less regularly read than were the magazines and newspapers.

One-half of the young men and women were members of no formal organization of any kind. The organizations to which the young men and women belonged were the church, the grange, the farm bureau, and the home bureau.

Those interviewed suggested that communities were doing little for the young people, and that provision be made for social and recreational needs. They recognized sociability as a chief need.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Selected list of American agricultural books (*U. S. Dept. Agr., Library, 1936, pp. [3]+41*).—This is a mimeographed selected list of approximately 460 cyclopaedias and books on general agriculture; crops; soils; fertilizers; horticulture; landscape gardening; forestry; animal husbandry; dairying; plant and animal breeding; bees; insect pests; insecticides and fungicides; plant diseases; agricultural science; farm buildings, agricultural engineering, and agricultural machinery; agricultural economics; rural sociology; and agricultural history.

Space and equipment for homemaking instruction (*U. S. Dept. Int., Off. Ed., Vocat. Ed. Bul. 181 (1935), pp. 153, figs. 148*).—This is a guide to the location and arrangement of homemaking departments in vocational teaching. The location, layouts, space requirements, furnishings and equipment, and general storage for activities relating to different types of work, and general considerations—heat, ventilation, light, electricity, floors, etc.—are discussed with numerous illustrations, floor plans, etc. The preparation of teachers and the functions of home economics supervision are also discussed.

Consumer-buying in the educational program for homemaking (*U. S. Dept. Int. Off. Ed. Vocat. Ed. Bul. 182 (1935), pp. XIII+205*).—This bulletin was prepared to serve as a guide for teachers in secondary schools and in the field of adult education principally in determining what to teach to groups at different educational levels, in planning for the more effective types of organization in which to include consumer-buying education, in developing effective methods of teaching, in selecting and using references and illustrative material, in utilizing local facilities for worthwhile consumer-buying programs, and in determining in an experimental way with a given group the solution of certain problems in consumer-buying.

Chapter I discusses the need for education in consumer-buying and its relation to other aspects of homemaking. Chapter II, suggestions for consumer-buying at the secondary school level, discusses the contribution of different high school subjects to consumer-buying and other parts of consumer education and the bases for determining emphasis in consumer-buying, and makes suggestions for programs in consumer-buying. Chapter III, suggestions for consumer-buying education for adults, deals with the planning for the program in the community, the adapting of methods to adult needs, and program possibilities for adults. Part II, outlines and source material, outlines the major objectives, including for each a statement of minor contributing objects, suggestions for content, illustrations of pupils' experiences, and a list of references.

World progress in home economics, 1927 to 1934, I. H. Gross (*Jour. Home Econ., 28 (1936), No. 4, pp. 233–240*).—This is a brief of the General Report, Section I, from the Fifth International Congress of Home Economics held in Berlin in 1934, to which 17 countries sent representatives.

In this brief the likenesses and differences among the countries in the curriculum and teaching methods in the schools, extension, research, special courses, and training of teachers have been considered and particularly compared with that of the United States.

An accompanying list summarizes the points stressed in the reports of the International Congress and the progress made in home economics since 1927.

FOODS—HUMAN NUTRITION

[**Food and nutrition studies by the Massachusetts Station**] (*Massachusetts Sta. Bul. 327 (1936), pp. 35, 36, 37, 59, 60, 62, 63*).—Included in this annual report are summaries of studies, several of them representing extensions of earlier work (E. S. R., 73, p. 711), by W. S. Mueller and W. S. Ritchie on the nutritive values of plain and chocolate-flavored milks (pp. 35, 36); by M. J. Mack in cooperation with C. R. Fellers on the vitamin C content of orange-flavored drinks (p. 37); by H. S. Mitchell and O. A. Merriam on the cause and control of nutritional cataract (pp. 59, 60); by Mitchell and G. M. Cook on the use of banana and milk in diets for weight control (p. 60); by J. A. Clague on the number of micro-organisms on dried food (p. 62); by Fellers, Clague, F. P. Griffiths, W. S. Conway, Jr., and V. K. Watson on the Atlantic whiting, mackerel oil, and crab meat (p. 62); by Fellers, Clague, and W. Stepat on the ascorbic acid (vitamin C) content of raw, cooked, and canned rhubarb (p. 62); by Fellers, A. S. Levine, and W. A. Maclinn on home canning research (pp. 62, 63); by Fellers and J. Miller on the use of corn sugar in manufactured fruit and vegetable products (p. 63); by Fellers and Stepat on frozen food investigations (p. 63); by Fellers and Clague on the utilization of cull [illegible] (p. 63); by Merriam, Fellers, and P. D. Isham on nutritional studies on [illegible]

berries (p. 63); and by Fellers, Isham, W. B. Esselen, and R. E. Buck on vitamin D investigations (p. 63).

[Studies in foods and nutrition by the North Dakota Station], E. LATZKE and D. BERRIGAN (*North Dakota Sta. Bul. 286 (1935), pp. 68–72*).—This progress report includes summaries of studies on cooking methods for veal and edible meat byproducts, meat canning, the influence of cooking and canning on the content of vitamins B and G in meat, the effect of pasturage shortage on the quality and palatability of beef, the utilization of rhubarb for jelly and squash for sirup, the vitamin G content of Buttercup squash, and the use of lard in cake making.

[Studies in foods and nutrition by the Wisconsin Station] (*Wisconsin Sta. Bul. 435 (1936), pp. 56–67, 81, 82, 150, 151, figs. 2*).—Included in this progress report are summaries of studies, several of which represent extensions of earlier work (E. S. R., 74, p. 568), by G. O. Kohler, C. A. Elvehjem, and E. B. Hart on the availability of iron in common foods (p. 56); by M. O. Schultze, Elvehjem, and Hart on the availability of copper from natural sources (pp. 56, 57); by Elvehjem, D. R. Mendenhall, A. Siemers, and L. Willis on the response of children to iron and copper combined as compared with iron alone (p. 57); by H. J. Deobald and Elvehjem on the development of rickets through overdosage of iron (pp. 57, 58); by H. Steenbock in cooperation with M. H. Irwin, J. H. Weber, and E. Lease on the effects of feeding rancid fats to experimental animals (pp. 58, 59); by M. A. Ingraham and Steenbock on the synthesis of carotene from carotenoids in plants, including algae (pp. 59–61); by O. L. Kline, A. Arnold, Elvehjem, and Hart on the attempt at isolation of the growth factor of liver (pp. 61, 62); by H. Parsons, J. Lease, and E. Kelly on attempts to isolate the toxic factor of raw egg white (p. 62); by D. Husseman on the home canning of tomato juice to preserve its vitamin C content (pp. 62, 63); by Elvehjem and Arnold on the vitamin B_1 content of animal tissues and the stability of this vitamin during the canning of meat at different temperatures (pp. 63, 64); by Elvehjem and C. J. Koehn on the separation of flavines from vitamin G in liver (p. 64); by Kline, H. R. Bird, Elvehjem, and Hart on the development of a new synthetic ration for the study of vitamin B_4 (pp. 64–66); by F. C. Schoenleber and Steenbock on the stability of vitamin B_1 and the destruction of vitamin C (pp. 66, 67); by C. A. Bauman on the stability of vitamin A in milk during irradiation (p. 67); by R. W. Haman and Steenbock on the relative antirachitic potency (for chicks) of irradiated milk and yeast milk and of irradiated plant and animal fats (p. 67); by P. L. Pavcek, W. H. Peterson, and Elvehjem on factors influencing the growth and vitamin B_1 content of baker's yeast (pp. 81, 82); and by M. L. Cowles a survey of winter dietary deficiencies in 109 farm families.

Some methods and apparatus used in measuring the quality of eggs for cake making, F. B. KING, H. P. MORRIS, and E. F. WHITEMAN (*Cereal Chem., 13 (1936), No. 1, pp. 37–49, figs. 4*).—In this contribution from the U. S. D. A. Bureau of Home Economics, detailed methods are described for measuring the lifting power of eggs, based on quantitative measurements of specific volume, tensile strength, and compressibility of sponge cake. Cake volumes were measured by the planimeter method, as described by Platt and Kratz (E. S. R., 69, p. 462), and also by seed displacement, with preference given to the latter as being more rapid and giving more consistent results. Tensile strength was determined essentially as described by Platt and Kratz except that a special miter box was used for the cutting of the sample. Compressibility was determined by means of a penetrometer similar to that described by Bonney, Clifford, and Lepper (E. S. R., 65, p. 190).

The data reported include pH, total CO_2 in 100 cc, and the total solids of the white, yolk, and magma and the viscosity of the magma of two series of eggs from mature hens and one from pullets, and the physical measurements noted above for a series of sponge cakes made from the same eggs. "Most uniform results were obtained when the cake batter was added to the pans one-third at a time in rotation, followed by making the quantitative measurements on the finished cakes in a room kept at constant temperature and humidity. The measurements of H-ion concentration, total carbon dioxide of white and yolk, viscosity of magma, total solids of white and yolk of fresh eggs do not appear to be definitely related to the quantitative cake measurements."

Utilization of meat by human subjects, II, III (*Jour. Nutr., 9 (1935), No. 6, pp. 677–683, 685–690*).—In continuation of this series of studies at the Kansas Experiment Station (E. S. R., 73, p. 869), two papers are presented.

II. *The utilization of the nitrogen and phosphorus of round and liver of beef*, Z. Long and M. S. Pittman.—As determined by the same methods as in the first study, the nitrogen of the round of beef was found to have almost the same coefficient of digestibility as that of beef liver. A slightly more favorable nitrogen balance was obtained on the round than on the liver. The phosphorus balance was but little lower, in spite of the fact that the diet supplied less than two-thirds as much phosphorus as in the period in which liver was used. As collagen and elastin were higher in the round than in the liver, these constituents could not have affected seriously the utilization of the total nitrogen of the cut.

III. *The utilization of the nitrogen and phosphorus of beef heart*, B. L. Kunerth, I. M. Chitwood, and M. S. Pittman.—The nitrogen of beef heart was found to be utilized at least as well as that of beef round, as judged by practically identical coefficients of digestibility and losses of urinary nitrogen. Slight differences in phosphorus utilization were in favor of the heart. The greater amount of connective tissue in the heart apparently did not prevent good utilization of both nitrogen and phosphorus.

The cooking quality, palatability, and carbohydrate composition of potatoes as influenced by storage temperature, R. C. Wright, W. M. Peacock, and T. M. and E. F. Whiteman (*U. S. Dept. Agr., Tech. Bul. 507 (1936), pp. 20, fig. 1*).—In this investigation, a preliminary report of which has been noted (E. S. R., 65, p. 891), four varieties of potatoes were grown on the Arlington Farm, harvested when practically mature, and stored at controlled temperatures, usually 32°, 36°, 40°, 50°, 60°, and 70° F. for 65 days in 1929 or 124 days in 1931. The potatoes were then steamed, boiled, baked, french fried, and made into chips by a definite procedure for each method of cooking. The cooked products were judged while hot (except for the chips), and without added salt, by eight or nine judges for flavor, texture, and color.

For steaming, baking, and boiling, the best products followed when the potatoes were stored at temperatures of 50°, 60°, and 70°. Those stored at lower temperatures were less acceptable in quality, having an increased yellow color, a soggy or watery texture, and an unpleasantly sweet flavor. The best temperatures for storing potatoes for french fries were found to be 50°, 60°, and 70°, and for potato chips 60° and 70°.

Carbohydrate analyses were made by the described method at three successive periods, one coinciding with the cooking tests. For all varieties the sugar content increased as storage temperatures were lowered. With this increase the quality of the cooked product became poorer. Potatoes stored at 50°, however, showed upon analysis that their sugar and carbohydrate was almost the same as when these were put into storage.

Potatoes stored for 6 weeks at 40° and then moved to 70° for 6 weeks had a sugar content similar to lots when first put into storage. Lots stored at 36° and 32° and moved to 70° showed a relatively high sugar content. Potatoes stored for 6 weeks at 60° and 50° and then moved to 40° for 6 weeks showed an increase of sugar over those remaining continuously in storage at 40°.

Soybeans and soybean products for table use, E. J. KINGSLEY (*U. S. Dept. Agr., Bur. Home Econ.* [*1935*], *pp. 17*).—This mimeographed paper contains general information on field and garden varieties of soybeans, on their nutritive value, and on ways of preparing them for table use, both green and dried. Several recipes and directions for canning green soybeans are given. Soybean sprouts, flour, milk, curd, and a mash made from dried soybeans are described, their method of preparation and uses in the diet are given, with recipes.

Dietary uses of the banana in health and disease, L. J. BOGERT (*New York: United Fruit Co., 1935, pp. 32, figs. 2*).—This compilation of information on the banana includes its composition, its value as a food for adults, infants, and young children, and its use in various diseases and functional disorders.

The nutritive value of fungi, II, III, H. J. GORDICA, W. H. PETERSON, and H. STEENBOCK (*Jour. Nutr., 9 (1935), No. 6, pp. 691–714, figs. 9*).—In continuation of an earlier study at the Wisconsin Experiment Station in which it was shown that dried mycelium of *Aspergillus fischeri* and *A. sydowi* contain sufficient vitamin B complex to promote good growth of young rats and afford complete protection against polyneuritis at a 20-percent but not at a 5 percent level, further work was undertaken as noted below.

II. *The vitamin B, G, and B_4 content of the mycelium of Aspergillus sydowi* (pp. 691–700).—The addition of 10 percent of the mycelium of *A. sydowi* to a vitamin B-(complex) deficient diet furnished enough of the vitamin B complex to support good growth in rats, although better growth and performance were secured on 20 percent of the mold.

The mold at a 10-percent level furnished complete protection to chicks against polyneuritis, and at a 1-percent level prevented symptoms of pellagra in chicks on a ration low in vitamin G. On this diet good growth was not secured at levels below 3 percent. Mold added at a level of 30 percent to a diet deficient in vitamin B_4 completely prevented the onset of paralysis in chicks.

III. *The growth of rats on supplemented and unsupplemented mold proteins* (pp. 701–714).—The proteins of ground fresh mycelium from *A. sydowi* grown on a synthetic medium of inorganic salts and glucose were found insufficient to promote more than a slight amount of growth or to sustain life in young rats for a period longer than from 7 to 9 weeks when fed in amounts constituting 50 percent (dry basis) of the basal ration.

The most effective supplements to the mold proteins were the proteins of whole wheat and gluten feed, which supported very good growth when added to the basal ration at a 2.5- or 5-percent level. Good growth was secured with casein, skim milk protein, egg white, and yeast protein fed at levels of 2.5 and 5 percent as supplements to the mold protein, with better growth at the higher level. Gelatin at the same levels did not improve the growth-promoting power of the mold protein, nor was there any improvement in growth on the addition of 0.5 percent cystine, 0.5 percent histidine, 1 percent tyrosine, or 0.5 percent cystine plus 1 percent tyrosine to a ration containing 18 percent mold protein.

Proper processes for home canners, F. W. TANNER (*Jour. Amer. Dietet. Assoc., 11 (1935), No. 1, pp. 18–27, fig. 1*).—This is a further discussion (E. S. R., 73, p. 714) of various methods of canning in the home and of the dangers

involved in the use of any method other than steam pressure cooking in the processing of nonacid foods. In answer to the question "Must home-canned foods be sterile?" the statement is made that "spores of *Clostridium botulinum* should be destroyed and procedures should be used which will insure this. Other spoilage is the individual's problem. Home canners may perhaps accept much larger percentages of spoilage than factory canners."

The iodine content of foodstuffs [trans. title], R. BALKS (*Ztschr. Untersuch. Lebensmtl., 71 (1936), No. 1, pp. 76–93*).—Data are reported on the iodine content of samples of drinking water and milk from all of the districts of Westfalen (Westphalia); of potatoes, cabbage, carrots, and spinach grown on typical light and heavy soils in the same climatic zone; of carrots and spinach grown on soils fertilized with varying amounts of iodine; and of soils and various foods from goiter-free and goiter-endemic districts of Westfalen.

On the average, the iodine content of the water was within normal range and the content in the milk high. The vegetables grown on light and heavy soil types showed no characteristic differences in iodine content. The iodine content of spinach varied in proportion to the content of the soil in which it was grown and increased with iodine fertilization of the soil. Corresponding variations in the iodine content of carrots were found, but in contrast with spinach the addition of iodine to the soil increased the iodine content to only a slight degree. In the spinach samples grown with and without iodine fertilization, the iodine appeared to be in the same bound form. In endemic goiter regions the iodine content of the soils and vegetables grown thereon was smaller than in the goiter-free localities.

The copper content of urine of normal children, A. ROSS and I. M. RABINOWITCH (*Jour. Biol. Chem., 111 (1935), No. 3, pp. 803–805*).—An earlier study of the copper content of the urine of normal adults (E. S. R., 70, p. 130) has been extended to 50 boys between 8½ and 17½ yr. of age and normal except for noninflammatory orthopedic conditions.

The copper content of the urine ranged between 0.04 and 0.52 mg, with an average of 0.3 mg per liter and between 0.026 and 0.62 mg, with an average of 0.16 mg per day. In comparison with the figures obtained for adults, the concentrations of copper in the urine were similar, but the average amount excreted daily was appreciably smaller.

Blood buffer values in mineral deficiency, I. N. KUGELMASS (*Amer. Jour. Digest. Diseases and Nutr., 2 (1936), No. 12, pp. 730–732, fig. 1*).—The buffer values of the blood serum obtained from normal and rachitic infants have been determined electrometrically for the entire pH range. When plotted against the values of a nonbuffered solution, the curves obtained showed a marked diminution in the blood buffer capacity in rickets. This is thought to explain the relative instability of the acid-base mechanism in rickets and to indicate the importance of emphasizing base-forming foods such as milk, fruits, and vegetables in addition to vitamin D in the treatment of rickets.

The intermediary metabolism of fructose and galactose, H. J. DEUEL, JR. (*Physiol. Rev., 16 (1936), No. 2, pp. 173–215*).—"In the present review, the fate of fructose and galactose has been compared with that of glucose through the various stages in their intermediary metabolism. Absorption, transportation in the blood, glycogen formation, oxidation, ketolysis, and tolerance have each been considered in turn. The site of transformation to glucose, as well as the action of insulin on various processes, have been discussed."

An extensive list of literature references is appended.

The nutritive value of lactose in man, A. E. KOEHLER, I. RAFFETY, E. HILL (*Jour. Nutr., 9 (1935), No. 6, pp. 715–724, fig. 1*).—Lactose in

of 1.5 g per kilogram of body weight was given to 18 normal, 16 obese, and 18 diabetic subjects in the morning in a fasting state, and venous blood and urine samples were collected hourly for 4 hr. for glucose determinations. If the urine specimens gave a positive reduction test, the fermentability of the sugar was determined. In a small group of the normal subjects the blood inorganic phosphate changes after lactose ingestion were also studied. For purposes of comparison the blood sugar and urinary excretion were studied in 26 apparently normal subjects after glucose ingestion and in 6 normal subjects after starch ingestion. The recovery in the urine of lactose administered intravenously was also studied in 5 normal, 3 obese, and 3 diabetic subjects.

The average blood sugar values of normal subjects showed no important change after lactose ingestion, although individual variations were noted. The ingestion of starch caused nearly as great a rise in blood sugar as that following the administration of glucose and with a much greater total hyperglycemia. In the obese subjects there was a slight but definite elevation in blood sugar values after lactose ingestion, and in the diabetic subjects nearly as marked changes as after glucose ingestion.

The average recovery in the urine of intravenously injected lactose was approximately the same (89.3–93.2 percent) in the three groups of subjects. Ingested lactose caused a small fall in the inorganic phosphate content of the whole blood. In the normal subjects there was frequently a lactosuria after the ingestion of lactose, but this was never noted in the diabetic subjects.

In commenting upon these findings the authors suggest the possibility of a difference in the alimentary assimilation of lactose by the normal and diabetic subjects. They also call attention to the rapid rate of passing of lactose through the small intestines in the normal subject. "Such a rapid rate could easily interfere with hydrolysis and absorption even though lactase were present. Not only could the increased intestinal rate caused by lactose delay its absorption, but it could also interfere with the absorption of other foodstuffs."

Some normal variations in the emptying-time of the human stomach (using a carbohydrate meal), E. J. VAN LIERE and C. K. SLEETH (*Amer. Jour. Digest. Diseases and Nutr., 2 (1936), No. 11, pp. 671, 672*).—Data are reported on the emptying time of the stomach, as determined with the fluoroscope, following the consumption of a standard farina meal. Nine subjects, all normal young male medical students, were used in a total of 77 tests.

The emptying time of the stomach of any individual remained strikingly uniform from day to day, but great variations were found among the different individuals. The extremes of the individual averages were 1.03 and 2.81 hr., and the minimum, maximum, and average values for the separate tests 0.75, 3.5, and 2.08 hr., respectively.

The effects of prolonged muscular exercise on the metabolism, F. C. GOODHART and C. G. DOUGLAS (*Roy. Soc. [London], Proc., Ser. B, 119 (1936), No. 815, pp. 381–439, figs. 12*).—The authors served as subjects in this investigation of the effects of a long walk on the general metabolism of subjects not in athletic training. In most of the experiments the exercise, which was taken for the most part in the postabsorptive state after a normal diet, consisted in walking 10 miles on practically level gravel paths at a rate of 4.5, and in a few instances 3.5, miles per hour.

For both subjects the respiratory quotient during the work rose somewhat above the preliminary resting values in the early stages and fell gradually as the work continued. These changes could not be ascribed to accumulation of excess lactic acid in the blood, to a rise of body temperature, to changes in the CO_2-combining power of the blood, or to a developing ketosis. During

rest after exercise the respiratory quotients fell to average figures of 0.76 and 0.73 for the two subjects, respectively, and remained at these low figures for from 3 to as long as 9½ hr. The fall in respiratory quotient was accompanied by a definite excess of ketone bodies in the blood and by a progressive fall in the CO_2-combining power. Ketosis never developed during an uninterrupted walk, but appeared very soon after the beginning of the rest period and was associated with the total amount of muscular work done previously rather than with the rate at which the work had been done.

In experiments in which a high carbohydrate diet had been taken on the previous day, the general course of the respiratory exchange was about the same as following the normal diet, although the respiratory quotient was at a higher level. However, no ketosis developed after the exercise, nor was there a progressive fall in the CO_2-combining power of the blood. On the other hand, when the exercise was taken after a normal diet on the previous day and a normal breakfast, or 50 g of fructose or glucose with from 20 to 40 g of bread just before the exercise, postexercise ketonuria developed in the majority of the experiments, and the respiratory quotient fell nearly as low as in the normal postabsorptive state. "Confirmation has, therefore, been obtained of the view that a diet rich in carbohydrate taken on the day preceding the exercise may in certain respects have a greater influence than the ingestion of a quantity of easily assimilable carbohydrate shortly before beginning the work."

The economy of muscular exercise, D. B. HILL (*Physiol. Rev., 16 (1936), No. 2, pp. 263–291, figs. 2*).—In this review the term moderate work is used for activity which is less than three times, and maximal work for activity more than three times, the basal rate. Any activity between these limits is considered hard work. "In the first category the amount of energy transformed is small, the effects of the physical environment almost negligible, and if fatigue occurs it is of remote rather than of direct interest to the physiologist. With work approaching the limit of capacity, environmental conditions become more important. Fatigue appears to depend on the ratio of the work done to the capacity for work. In maximal work a temporary steady state may be attained, but a break-down eventually occurs for which any one of several functions may be responsible. The most intense work is chiefly anaerobic, and here no steady state is reached. Fatigue increases with the rapid depletion of energy reserves and the accumulation of unoxidized end products."

A modification of the Sherman method of studying the multiple nature of vitamins, with an application to vitamin G, T. S. HAMILTON and H. H. MITCHELL (*Jour. Nutr., 10 (1935), No. 2, pp. 117–128*).—The technic for determining whether or not a given vitamin has a multiple nature, first described by Sherman and Axtmayer (E. S. R., 58, p. 295) and later used by Stiebeling (E. S. R., 68, p. 568) and by Page (E. S. R., 71, p. 731), has been modified by using the paired feeding method of Mitchell and applied to the problem attacked by Page relative to the multiple nature of vitamin G. The results led to the conclusion that two vitamin G fractions prepared from skim milk powder according to the directions of Page show no evidence of the multiple nature of the vitamin. It is emphasized that "both the precision and the clarity of vitamin assay methods are improved by controlling the consumption by the experimental animals of the basal diet, as well as of the vitamin supplements."

Relation of castration to vitamin A-deficiency in the rat, K. H. MASON and J. M. WOLFE (*Jour. Nutr., 9 (1935), No. 6, pp. 725–734, figs. 2*).—Data are presented which confirm previous observations of Evans and Bishop (E. S. R., 50, p. 163), Baumann and Steenbock (E. S. R., 69, p. 630), Aberle [illegible]

p. 759), and others as to the sensitivity and reliability of continuous vaginal cornification as a criterion of early vitamin A deficiency. It is shown further that complete castration causes no significant difference in the time of appearance of continuous vaginal cornification or xerophthalmia in vitamin A-deficient rats of either sex, but that the castrate rat is less satisfactory than the noncastrate in following the repair of vaginal cornification during vitamin therapy.

Changes in the vaginal epithelium of the rat after vitamin A-deficiency, K. E. MASON and E. T. ELLISON (*Jour. Nutr., 9 (1935), No. 6, pp. 735–755, pls. 2*).—The changes occurring in the dry stain vaginal smears of castrate, noncastrate, and pregnant rats during the development of vitamin A deficiency and subsequent therapy are described in detail as observed in the examination of more than 52,000 vaginal smears.

In discussing the value of the test as a method for the biological assay of vitamin A, the authors state that "the vaginal smear test seems best applicable to the measurement of the interval elapsing between the repair of, and the return of, vaginal cornification following administration of single doses of vitamin A-containing substances. Unlike the other criteria of A deficiency (xerophthalmia and growth plateau), vaginal cornification is not significantly influenced by other factors (differences in inherent growth capacity of the test animal, general debility, extraneous causes of ocular irritation and infection) which may alter the reparative response when measured by other methods of assay. The lesser degree of A depletion required in the test animal, and the utilization of the same animal for repeated tests at intervals of a few weeks, offer additional advantages."

Attention is also called to recent clinical observations by J. W. Simpson (personal communication) showing the efficacy of a high intake of vitamin A in the treatment of senile vaginitis, thus suggesting that vitamin A is essential for the maintenance of a normal healthy state of the vagina in the human.

The demonstration of oestrus in the vitamin A-deficient rat by supravital study of the vaginal smears, K. E. MASON and E. T. ELLISON (*Jour. Nutr., 10 (1935), No. 1, pp. 1–11, figs. 2*).—In this further study of the vaginal smear test for detecting vitamin A deficiency, the supravital vaginal smear modification was used to demonstrate oestrus cycles in vitamin A-deficient animals in which abnormal cornification was too severe to permit their identification by dry stain smears. With the use of this method it was possible to differentiate between the effects of vitamin A deficiency and inanition on the vaginal epithelium. "The excessive keratinization, which more or less masks the underlying cyclic changes, is a primary response of the vaginal epithelium to lack of vitamin A. The increased lengthening of the cyclic change is indirectly due to associated growth retardation and decline."

The importance is emphasized of using for this test animals which show unusually good growth and vigor during the weaning period.

The vitamin contents of Philippine foods.—IV, Vitamins A and B_1 in various fruits and vegetables, A. J. HERMANO and P. J. AGUILA (*Philippine Jour. Sci., 58 (1935), No. 4, pp. 425–433*).—In this continuation of the series of papers noted previously (E. S. R., 73, p. 423), data are reported on the vitamin A content of 14 samples and the vitamin B_1 content of 10 samples of Philippine fruits and vegetables purchased on the open market. The samples were usually dried in an electric oven at 80° C. and fed in powdered form mixed with the basal diet to the extent of 10 percent of the diet. In the case of some of the fruits the samples were fed in 2-g amounts daily as a supplement to the basal diet.

Among the materials reported to be good sources of vitamin A were the lemosa fruit (*Artocarpus champeden*), the leaves of pechai or Chinese cabbage (*Brassica chinensis*), fern (*Ceratopteris thalictroides*), saluyot (*Corchorus olitorius*), squash (*Cucurbita maxima*), sweetpotato or kamote (*Ipomoea batatas*), pods of segadilla (*Psophocarpus tetragonolobus*), and frozen mango (*Mangifera indica*).

Of the samples tested for vitamin B_1 the tender leaves and tops of squash gave the best results, followed by the leaves and tops of mustard, saluyot, and sweetpotato, and the fruit of santol (*Sandoricum koetjape*).

The effects on the gastric juice of man of six weeks' deprivation of vitamin B_1, W. C. ALVAREZ, F. PILCHER, M. A. FOLEY, A. MAYER, and A. E. OSTERBERG (*Amer. Jour. Digest. Diseases and Nutr., 3 (1936), No. 2, pp. 102–107, figs. 3*).—Two adult subjects subsisted for 6 weeks and 1 for 2 weeks on a diet markedly deficient in vitamin B_1. Gastric analyses were made nearly every day, and the hemoglobin content and erythrocyte count of the blood were determined frequently.

One of the 2 subjects remaining on the experiment for 6 weeks developed a sore throat and later a cold, both of which were followed by a decrease in the acidity of the gastric juice but not in its pepsin content. In the other 2 there were no definite changes in the gastric juice throughout the experiment. The most striking change observed in all 3 subjects was in the hemoglobin content of the blood, which fell about 11 percent in spite of the fact that the iron content of the diet approached the Sherman standard for minimal requirement. There was also a drop of 7 or 8 percent in the erythrocyte count.

Vitamin C, ascorbic acid, C. G. KING (*Physiol. Rev., 16 (1936), No. 2, pp. 238–262*).—This review of the literature on vitamin C since 1932 is presented under the following headings: Identification and isolation, synthesis and general chemical properties, methods of analysis, biological methods of assay, physiological functions, and studies in relation to the general food supply.

An extensive list of literature references is appended.

Ascorbic acid (vitamin C) in sprouted oats, R. BOGART and J. S. HUGHES (*Jour. Nutr., 10 (1935), No. 2, pp. 157–160, figs. 2*).—In this contribution from the Kansas Experiment Station, the authors call attention to the fact that sprouted oats has proved a satisfactory winter source of vitamin C for guinea pigs. The method of sprouting is described, and data are given on the vitamin C content, as determined chemically by the technic of Bessey and King (E. S. R., 71, p. 137), of oats at different stages of sprouting from the first to the thirteenth day. A steady increase in vitamin C was shown up to the tenth day, after which there was a slight decrease. There was but little difference between the vitamin C content of oats sprouted in the light or dark.

A study of the distribution of the vitamin in the various parts of the plant at the seventh day of sprouting showed that over 90 percent of the vitamin was contained in the epicotyl. The remainder was distributed fairly evenly between the root and the kernel, with slightly more in the kernel. The quantity of vitamin C in 40 g of sprouted oats (the amount customarily included in the ration) was estimated to be between 6 and 7 mg, or considerably in excess of the requirement.

Vitamin content studies.—XVII, Apple marmalade enriched and not enriched with a concentrate of pine needle infusion as a source of vitamin C [trans. title], N. JARUSSOWA (*Ztschr. Untersuch. Lebensmtl., 70 (1935), No. 6, pp. 538–540*).—A commercial apple marmalade showed no antiscorbutic potency when fed to guinea pigs in daily doses of 1.5, 3.8, and 6 g, but the same marmalade enriched by the addition of 10 percent of a pine needle [illegible]

concentrate was protective in 3.8-g doses. It is calculated that such a marmalade would furnish sufficient vitamin C for man in amounts of 60 g daily.

Observations on the estimation of ascorbic acid by titration, E. W. McHENRY and M. GRAHAM (*Biochem. Jour., 29 (1935), No. 9, pp. 2018–2019, fig. 1*).—This paper describes a series of modifications in the titration procedure of Harris and Ray (E. S. R., 70, p. 426) and two methods of removing plant pigments before the titration. Data are then reported showing the rapid destruction of the vitamin in shredded or minced vegetables, a higher concentration in the parts of plant tissues in which photosynthesis is most active such as the top v. the lower part of head lettuce and the skin v. the inner edible portion of cucumbers, and an inverse relationship between size and vitamin content of ripe tomatoes. A more complete report is also given of previously noted studies on the quantities of reduced and reversibly oxidized ascorbic acid in various tissues (E. S. R., 73, p. 745) and the effect of cooking on the titration value (E. S. R., 73, p. 746).

TEXTILES AND CLOTHING

Application of the seed cotton fibrograph to lint cotton, K. L. HERTEL (*Jour. Tenn. Acad. Sci., 11 (1936), No. 2, pp. 147–152, fig. 1*).—Results of research at the University of Tennessee show that optical analysis may be applied advantageously to a cotton sample that contains parallel fibers in proportion to both their length and their length-frequency, and that has the fiber ends distributed at random, a distribution occurring in slivers, rovings, and yarns. The sample may be obtained by clamping a sliver or roving on a transverse line and combing out all fibers not held by the clamp. The resulting fibrogram pictures the arrangement of fibers as they appear in the yarn, and is also equivalent to the integral of the length-cumulative frequency curve of the cotton, or to the second integral of the length-frequency distribution curve.

A tangent to the curve at a point $l=l_1$ intercepts the length-of-fibers axis at the mean length of all fibers longer than l_1, and it intercepts the frequency axis at a distance from the origin proportional to the relative weight of the same fibers. A tangent at $l=0$ has an l intercept equal to the mean length of all the fibers in the sample.

The influence of position isomerism (structural differences) in azo dyes upon their fastness to light and washing, M. E. GRIFFITH and W. R. BROWN (*Ohio Sta. Bul. 565 (1936), pp. 19, Nos. 4*).—In this study the influence of the position of the sulfonic acid group in a series of isomeric monoazo dyestuffs on the properties of the dyestuffs was determined. Aniline and the ortho-, meta-, and para-sulfonated anilines were coupled to a series of naphthol sulfonic acids. The series of dyes were chosen so as to include a number of commercially important intermediates. Thirty-seven monoazo isomeric dyestuffs were prepared. The formula and properties, percentage of nitrogen, relative solubility in water at 20° C., and color of dye were noted. Other properties studied included visible absorption spectra, exhaustive properties, and the amount and kind of fading produced by light and washing tests.

White wool cashmere samples weighing 3.25 g were used for the application of dyestuff. The washing tests were made in a launderometer at 49°, using 100 cc of a 0.5 percent neutral soap solution. The machine was allowed to run for 30 min., after which the samples were rinsed several times in warm water, then in cold, squeezed, and dried in a current of air at room temperature before a fan. The tests for color fastness to light were made in a fadeometer, using the carbon arc as the source of artificial light. Tests of from 40 to 50

fadeometer hours were usually adequate to determine whether or not a color would fade, although some samples were exposed for 80 and 120 hr. Numerical expression for the loss of color due to washing was obtained by expressing the change in terms of percentage difference in reflectance at any one wave length. The degree of exhaustion varied with the different dyestuffs from 5 to 30 percent.

The position of the absorption band was only slightly affected by the position of the sulfonic acid group in the diazotized nucleus except that when this group was in the para position there was a decided shift of the band toward the red, as well as an increase in intensity. The position of the band fell between 470 and 500 mμ with the ortho- and meta-sulfonated compounds. The α-naphthol dyes had the greatest transmission in the yellow absorption band. The addition of a sulfonic acid group in the 3 position shifted the band to the red, in the 4 position still further to the red, and in the 5 position to the blue. The β-naphthol dyes had a greater absorption of blue than the α-naphthol dyes. The addition of the sulfonic acid group in the 6 position shifted the band to the red and in the 7 position to the blue. The disulfonic dyes showed very little difference, although the β-naphthol-6,8-disulfonic acid dyes showed more absorption of the blue than the others.

The percentage of absorption of the dyestuff by the wool was influenced by the presence of a sulfonic acid group in the diazotized nucleus. The ortho- and para-sulfanilic acid dyes were absorbed to a greater extent by the fiber than the meta-sulfanilic acid dyes. Substitutions in the naphthol ring had little effect upon the percentage of dyestuff absorbed. Color fastness to washing was increased by the presence of a sulfonic acid group in the diazotized nucleus, although the position had little or no effect. Substitutions in the naphthol nucleus did not greatly affect the fastness. Two types of light fading were observed—loss of intensity of color expressed as fading and change in hue called darkening. The ortho-sulfanilic acid dyes, both the mono- and disulfonic acid, were decidedly better than those of the other three series in color fastness to light. The β-naphthol dyes faded less than the α-naphthol dyes. The degree of darkening was little influenced by the presence or position of the sulfonic acid group in the benzene ring, although there was slightly less darkening in the case of the ortho- and para-sulfanilic acid dyes. The combined effect of fading and darkening indicated that the ortho-sulfanilic acid dyes were superior to the other three series. The combined effects of light and washing on the color fastness of the dyestuff, expressed as the utility factor, showed that ortho-sulfanilic acid dyes have greatest fastness, para-sulfanilic acid second, meta-sulfanilic acid third, and aniline dyes least. A comparison of substitutions in the naphthol nucleus relative to fastness of the dyes showed that β-naphthol dyes were superior to the α-naphthol for both the mono- and disulfonic acid substituted dyestuffs.

Cotton fabrics as effected by variations in pressure and in length of exposure during ironing, K. M. DOWNEY and R. E. ELMQUIST (*U. S. Dept. Agr., Tech. Bul. 517 (1936), pp. 32, figs. 14*).—This is an extension of a previous study (E. S. R., 71, p. 428) on three sheeting materials to determine the damaging effect on the fabric of variations in pressure and length of time of exposure. Deterioration was measured by breaking strength tests and by chemical and physical methods sensitive to small amounts of change.

Pressure exerted a considerable damaging influence on the fabric as shown by a decreased reflectance, methylene blue absorption, and breaking strength values and increased copper numbers and fluidity. For temperatures above 284° C., pressures of 4.0 lb. were three times more damaging

pressures. At 242° pressures of from 2.6 to 4.0 lb. were necessary to equal the damage done by 1.3 lb. at temperatures from 242° to 254°. Measurable change with the cool roll was first noted at 208° and 250° for the pressures of approximately 4.0 and 1.3 lb., respectively. The same initial changes were noted with the hot roll at temperatures 25° lower. The change from 1 to 60 sec. in still contact resulted in a small uniform increase in deterioration at 167° and a large rate of change decreasing considerably after 30 sec. at 255°. Exposures of from 5 to 15 sec. at 167° and 1.3 and 4.0 lb. pressure caused no deterioration, but 1.0 and 2.4 sec. caused measurable changes at the same limiting pressure at 255°. The rate of deterioration with pressure was greater for short than for longer exposures. The effect of pressure was comparable with that of time for short exposures, but less damaging for intervals beyond those at which small initial degradations occurred. The materials were scorched at 254.5°–141.5° for exposures from 2.4 and 30 sec., respectively, at the low pressures and 198°–132° for the same interval of exposure at the high pressures. This shows the effect of pressure to be six times as great for the short interval as for the long. After the first 5 sec. of exposure the rate of decrease of scorching temperatures was found to be less than 200°. Microphotographs of the scorched samples showed scorching to first affect the tips of the protruding fibers. The character of the deterioration was further evidenced by the fact that under constant pressure and time conditions small initial changes in reflectance occurred 70° lower than those in breaking strength. Fabrics ironed warpwise with the moving roll at 4 lb. pressure revealed a decrease of 1 or 2 threads to the inch in the filling count as compared with the count when the samples were passed through the ironer at 1.28 lb. pressure. With a filling decrease, an average increase of ½ thread was found for the warp. The thickness of the fabric decreased 4.5 percent. Microscopic observations confirmed this tendency toward displacement of filling yarns. With the still type of contact, the fabrics gave no evidence of displacement. Breaking strength tests showed a measurable change for the cool moving roll at pressures of 1.28 and 4.0 lb. at 321° and 286°, respectively. Corresponding values for the hot roll were obtained at 285° and 254°. For the still roll a continuous loss of strength was noted at 255° for all exposures up to 60 sec. at high pressure and from 5 to 60 sec. at low. An additional loss of 10 percent in strength was noted for samples having an initial reduction of 10 percent after the second ironing process. Tests on the elasticity of the fabrics showed that samples having a decrease in breaking strength of 42 percent had only a loss of stretch at break of 24 percent. Similar changes were noted for fluidity and breaking strength, though fluidity is more sensitive to small initial degradation. A decrease in methylene blue absorption was noted for all conditions of chemical change. The reduction in the copper number after an alkaline boil showed the oxidized cellulose to be of the reducing type, although with severe degradation there was evidence of the acidic type.

Severe scorching showed a greater relative change in reflectance in the red part of the spectrum than in the violet, and the solutions of cottons on which fluidity was determined became similar to truly viscous liquids. The moisture content of such damaged fabrics was considerably less than that of the undamaged fabric. Damage as indicated by the various tests was increased as much as 50 percent of the value when the padding of the roll was hard and unyielding, particularly at low pressure with both types of contact.

The three sheeting materials gave similar changes with the pressure and time-exposure treatments. One, however, designated as Strict Good Ordinary cotton was slightly more resistant to the damaging conditions than the other two representing Good Middling and Middling grades.

A study of children's wardrobes, M. PENNINGTON and I. H. GROSS (*Jour. Home Econ., 27 (1935), No. 10, pp. 647–649*).—Data were collected by the inventory method of interviewing the mothers of 71 families of East Lansing, Mich., who had children between 2 and 7 yr. of age and whose annual incomes ranged from $2,000 to $5,000. Information was obtained on the average number and content of garments found in the wardrobes of boys and girls, with costs at 1931 prices, the number of garments made in the home for girls and boys, and the number of garments handed down from other people.

HOME MANAGEMENT AND EQUIPMENT

A study of farm refrigeration methods, E. LATZKE and D. BERRIGAN (*North Dakota Sta. Bul. 286 (1935), pp. 72, 73*).—This progress report deals chiefly with the kerosene-operated refrigerators of the automatic continuous-burning and refueling types.

MISCELLANEOUS

Directory of field activities, compiled in the Office of Budget and Finance (*U. S. Dept. Agr., 1936, pp. 138; Sup. 1, p. 1*).—This is a geographical directory showing the field activities of the Department by the cities and towns at which employees are located in the States, Territories, possessions, and in foreign countries.

Report on the agricultural experiment stations, 1935, J. T. JARDINE, W. H. BEAL, ET AL. (*U. S. Dept. Agr., Off. Expt. Stas., Rpt. Agr. Expt. Stas., 1935, pp. 160*).—This report is discussed editorially on page 433.

Index to Department Bulletins Nos. 1–1500, M. G. HUNT (*U. S. Dept. Agr., 1936, pp. 384*).—This is a combined author and subject index.

Publications available for free distribution (*Idaho Sta. Circ. 75 (1936), pp. 4*).—A list of the station and extension publications available as of March 1936.

Annual report of the Massachusetts Agricultural Experiment Station, 1935, F. J. SILVERS ET AL. (*Massachusetts Sta. Bul. 327 (1936), pp. 84*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Agricultural research in New Hampshire: Annual report of director of New Hampshire Agricultural Experiment Station for the year 1935, J. C. KENDALL ET AL. (*New Hampshire Sta. Bul. 289 (1936), pp. 31*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. The text of the Bankhead-Jones Act (E. S. R., 73, p. 283) is included.

Experiment station progress: Report of North Dakota Agricultural Experiment Station for four years, July 1, 1931, to June 30, 1935, P. F. TROWBRIDGE ET AL. (*North Dakota Sta. Bul. 286 (1935), pp. 99, figs. 13*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Today's science for tomorrow's farming: Annual report of the director, [Wisconsin Station, 1935], compiled by N. CLARK and N. HOVELAND (*Wisconsin Sta. Bul. 435 (1936), pp. [2]+158+[3], figs. 32*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

NOTES

Connecticut [New Haven] Station.—Dr. Donald F. Jones, head of the genetics department, has returned from a year's absence on a research project at the California Institute of Technology.

Hawaii Station.—A 30-acre tract within easy driving distance has been transferred to the station for use as a substation. Adequate electric power and water for irrigation are available.

New divisions in the station have been set up in horticulture, plant pathology, and parasitology. These divisions are headed, respectively, by Drs. J. H. Beaumont, George K. Parris, and Joseph E. Alicata.

Iowa College and Station.—A brooder house, 30 by 136 ft., is to be built at the poultry husbandry experimental farm. It is planned to insulate this building very carefully and to install an oil heating unit which will maintain a controlled temperature, remove impurities from the air, and provide controlled humidification. In the summer the building may be cooled somewhat by the circulation of air from this unit. The capacity of the house will be approximately 7,000 chicks up to a period of 5 weeks of age.

Dr. R. A. Fisher, Galton professor of the University of London, served during the summer as guest professor in a 6 weeks' series of lectures to the station staff on statistics. At the conclusion of the series he was awarded the D. Sc. degree by the college.

Louisiana Station.—Dr. L. O. Ellisor has been appointed assistant entomologist beginning September 1.

Missouri University.—Dr. C. E. Marshall of the University of Leeds has accepted an appointment as visiting professor in the department of soils for the coming year.

Montana College and Station.—Recent appointments include the following: Vincent E. Iverson, as assistant professor of horticulture and assistant horticulturist; Dr. A. H. Walker, as assistant animal husbandman, vice W. F. Dickson resigned; W. B. Nelson, as instructor in agronomy in the college and assistant agronomist in the station, vice L. P. Reitz resigned to accept a position with the U. S. D. A. Bureau of Plant Industry; Ralph E. McCall, as assistant professor of animal husbandry and assistant animal husbandman, vice Ross H. Miller resigned; and P. S. Eckert, as instructor in agricultural economics and assistant agricultural economist, vice O. L. Mimms resigned to accept a position with the University of Idaho. Frank Barnum, assistant in animal husbandry, has resigned to become a county agricultural agent. J. E. Norton, superintendent of the Judith Basin Substation, has resigned to take up farming and has been succeeded by J. L. Sutherland. George W. Morgan, superintendent of the Northern Montana Substation, has retired and has been succeeded by Martin A. Bell.

New York State Station.—Additional State appropriations have been granted of $10,000 for studies of apple scab and other fruit tree diseases and $5,000 for studies of diseases of hops.

South Dakota Station.—The resignations are noted of Jeanette E. Ross, research chemist in textiles, and R. E. Henderson, assistant in farm management, the latter to accept a position with the U. S. D. A. Soil Conservation Service in Missouri.

EXPERIMENT STATION RECORD

VOL. 75 NOVEMBER 1936 No. 5

EDITORIAL

THE UP-STREAM ENGINEERING CONFERENCE AND THE YOUNG MEN'S CONFERENCE "ON BEHALF OF A CONTINENT"

Following a suggestion by Secretary of Agriculture Henry A. Wallace, two novel conferences were held in Washington, D. C., from September 22 to 24, 1936. The first of these was a 2-day gathering, known as the Up-Stream Engineering Conference. This was followed and supplemented by a 1-day session of the Young Men's Conference "On Behalf of a Continent."

The objectives of the Up-Stream Engineering Conference were outlined by President Franklin D. Roosevelt in a letter of authorization of June 16, 1936. In this letter he pointed out that "upstream engineering will have a major part in efforts to save the land and control floods. . . . The objects . . . are through forestry and land management to keep water out of our streams, to control its action once in the stream, and generally to retard the journey of the raindrop to the sea." "There are indications that a substantial body of technical information on the control of little waters is now available in the scattered records of American experience—Federal, State, and professional. The urgent problem is to bring these data together in a coordinate body of engineering knowledge so that public officials and engineers may have a more definite picture of the upstream engineering as an important field of public and professional activity."

As a committee to organize and promote such a conference, President Roosevelt appointed Mr. Hugh H. Bennett, Chief of the U. S. D. A. Soil Conservation Service; Mr. Morris L. Cooke, Administrator of Rural Electrification Administration; and Dr. F. A. Silcox, Chief of the U. S. D. A. Forest Service. This committee was assisted by a general committee of 73, among whom were representatives of the various bureaus of the Department of Agriculture and other Federal agencies, many of the agricultural colleges and experiment stations, and others, while the cooperating agencies included not only these groups but such bodies as the Association of Land-Grant Colleges and Universities, The American Engineering

91445—36——1

Council, the American Society of Agricultural Engineering, the American Society of Agronomy, the American Forestry Association, the American Meteorological Society, the American Soil Survey Association, the National Grange, the American Farm Bureau Federation, and 35 others interested in one or more phases from a national or regional point of view.

The program dealt broadly with the fundamental principles and considerations of land use and water control. One session, presided over by President H. P. Baker of the Massachusetts State College, considered especially the management and use of lands for forestry, range, and agriculture. The main paper as to agricultural lands was given by Mr. Bennett, and the discussion was opened by Mr. Noble Clark, assistant director of the Wisconsin Experiment Station, who emphasized the human relationships involved and made a vigorous plea for the consistent and symmetrical development of research as an essential foundation and accompaniment of any campaign for erosion control.

Realizing that a program of upstream engineering will be one of long duration, the Young Men's Conference was arranged to interest the potential future leaders in the problems of soil and water conservation. In addition to discussions of the purpose of the conference by its chairman, Dr. H. A. Morgan of the Tennessee Valley Authority, and Hon. Maury Maverick of Texas, as well as by leaders of soils, forest, and engineering activities, a distinctive feature was the presentation of brief reports by representatives of the 4-H Clubs, the Future Farmers of America, the Junior Chamber of Commerce, and the National Grange.

The two conferences brought together several hundred representatives of the hitherto more or less isolated agencies which are interested in the problems involved, and thereby exerted a valuable unifying and coordinating influence. The sessions were also of considerable public interest and appeal, and from this point of view were timely and abundantly worth-while.

DR. MARK FRANCIS (1863–1936)

A PIONEER IN EXPERIMENT STATION RESEARCH IN VETERINARY MEDICINE

A necrological tribute to Dr. Mark Francis, whose death occurred on June 28, 1936, ascribes to the late President William Oxley Thompson of Ohio State University the statement that if that institution had trained no other man in its entire existence it would have given back to the people more than they had ever expended upon it. This statement was doubtless occasioned by the distinctive

contributions of this pioneer in veterinary education and research at the Texas College and Station for nearly half a century.

Born in Shandon, Ohio, in 1863, Dr. Francis was graduated in 1887 from Ohio State University as the first student to receive its degree in veterinary medicine. Subsequently he studied at the American Veterinary College in New York City, the University of Michigan, and in Germany.

Dr. Francis joined the staff of the Texas College in 1888 as professor of veterinary medicine, continuing in this capacity till 1916 when the work was organized as the School of Veterinary Medicine, of which he became and remained dean. He also began work in 1888 as veterinarian of the newly organized Texas Experiment Station, and since the death of the late Dr. R. R. Dinwiddie in Arkansas in 1929 he had had the distinction of the longest period of continuous service in charge of station veterinary work.

The earliest studies which he carried on were with the screwworm, on which he reported in 1890. They were soon extended to other parasites and diseases of livestock, including liver flukes, blind staggers, glanders, and infectious anemia of horses and hog cholera. The work for which he became most widely known, however, was done on Texas fever, or, as he termed it, southern cattle plague. This project was begun under what was probably the first formal interstation cooperative agreement, made in 1888 by the Texas and Missouri Experiment Stations, the latter represented mainly by Drs. Paul Paquin and J. W. Connaway.

The contribution of Dr. Francis to this outstanding problem of its day was mainly in two directions. He sought means of immunizing northern cattle against the disease, treating thousands of head with injections of fresh blood from immune southern cattle and reducing under favorable conditions the prevailing mortality of 50 to 80 percent to approximately 5 or 6 percent. He also built in 1892 a device to spray cattle to destroy the ticks transmitting the disease and tested many dips in connection with this treatment, suggesting the use of the crude mineral oil which was employed almost exclusively from 1903 to 1911.

Dr. Francis was honored on many occasions by stockmen, his colleagues, and the public generally. Miami University conferred upon him the LL. D. degree in 1929, and a building on the Texas campus, which houses a notable collection of fossils of prehistoric animal life which he assembled, is designated Francis Hall. Yet beyond all this, as President T. O. Walton of the college pointed out on his birthday celebration in 1935, "he has built an enduring monument for himself in the hearts of those who know him and have made contacts with him. His State, his nation, the peoples of all the world have profited notably by his life's work."

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Results of work in agricultural chemistry.—I, II, edited by F. HONCAMP; III, edited by F. ALTEN and M. TRÉNEL (*Ergebnisse der Agrikulturchemie. Berlin: Verlag Chem., 1929, vol. 1, pp. VII+281, figs. 38; 1930, vol. 2, pp. 196, figs. 54; 1934, vol. 3, pp. 156, figs.* [17]).—These three volumes constitute the first three reports of proceedings of the agricultural chemistry section of the German Chemical Society.

The contents of volume 1 are: Chemistry and agriculture, by A. Binz, the distribution and cycle of iodine and its significance with relation to agricultural soils, by R. Griessbach; iodine in plant nutrition, by F. Ströbele; the iodine problem in animal nutrition, by K. Scharrer; the working together of the elements potassium and sodium in plant growth, by K. Maiwald; the tillage and fertilizer treatment of soils, by F. Alten; chemical and biological objectives of present methods of handling stable manures, by G. Ruschmann; laws of the decomposition of proteins, by W. Wöhlbier; procedures, practical considerations, and results of phosphoric acid determinations in soils, by E. G. Doerell; the lime reserves of our soils, by W. U. Behrens; the determination of the degree of saturation of soils acording to the newer methods, by H. Kappen; electrodialysis and the problem of mineral soil acidity by M. Trénel; the measurement of soil reaction, influences altering soil reaction, and their biological evaluation for agricultural purposes, by J. Görbing and W. Adolphi; and experiences in the determination of the lime requirement and controlling the degree of saturation of agricultural soils, by E. Pfeil.

Volume 2 deals with the composition of soil solutions and the growth of plants in very dilute solutions, by M. v. Wrangell; the determination of the nutrient content of soils by means of biochemical methods, by H. Niklas; the significance of the condition of the soil with respect to lime and to acidity and its determination by electrometric titration, by S. Goy; the absorption and utilization of phosphoric acid by plants, by Kleberger; the phosphoric acid content of the soil and treatment with phosphated fertilizers, with reference especially to biological relations, by O. Engels; the fertilizer treatment of acid soils, by H. Kappen; on the suspension effect, by G. Wiegner and H. Pallmann; the fertilizer effect of the anions and of the other constituents of potassic fertilizers, by O. Eckstein; the changes of nitrogen in green plants, by G. Klein; some new and noteworthy commercial feeding stuffs and their practical importance, by M. Kling; and the combating of forest damage by means of dusting with "Meritol" and a motor-driven dust sprayer, by H. Schotte.

The contents of volume 3 are divided into four sections—problems of agricultural chemistry, soils and fertilizer treatment, animal nutrition, and agricultural technology. Section 1 contains agricultural chemistry in the new state, by H. Niklas; and section 2 contains the status of soil analysis and its value in agricultural improvement, by F. Alten; the practical cooperation of agricultural chemists in agricultural group research, by R. Thun; the con-

servation of the productivity of soils, by W. U. Behrens; the physiological significance of mineral soil acidity, by M. Trénel and F. Alten; the economic significance of systematic investigations of soil reaction, by L. Schmitt; and the effect of fertilizers on wheat quality, by C. Pfaff. The third section contains comparative investigations of the physiological effect of the continued consumption of food materials grown with and without the use of commercial fertilizers, by A. Scheunert; the significance of the mineral composition of fodders for animal feeding, by A. Jacob; what problems fall to the chemist in the enforcement of the feedstuffs law? by L. Seidler; and the status of the science of animal nutrition in Germany, by W. Wöhlbier. Section 4 discusses whether the preparation of sugars from wood is economically desirable in Germany, by Spengler; and the preparation of fodder yeast from wood sugar, by H. Claassen.

Gmelin's handbook of inorganic chemistry.—IV, Nitrogen, pts. 2, 3 (*Gmelins Handbuch der anorganischen Chemie. System-Nummer 4: Stickstoff. Lief. 2, 3. Berlin: Verlag Chem., 1935, 8. ed., No. 4, pt. 2, pp. X+N283–N506, figs. 32; 1936, 8. ed., No. 4, pt. 3, pp. XIX+N507–N854, figs. 54*).—These two parts of the eighth edition of this well-known reference work (E. S. R., 73, p. 436) deal with the compounds of nitrogen with hydrogen and with oxygen, respectively, each of these topics being systematically taken up under numerous subheads.

Occurrence of selenium in the Colorado River and some of its tributaries, K. T. Williams and H. G. Byers (*Indus. and Engin. Chem., Analyt. Ed., 7 (1935), No. 6, pp. 431, 432*).—The upper parts of the Colorado and Gunnison Rivers were found to contain no selenium in excess of 1 part per billion, but showed increasing selenium content after receiving the drainage waters from seleniferous lands. It is noted in part, in this contribution from the U. S. Bureau of Chemistry and Soils, that "the source of the selenium in the drainage water is clearly evident through consideration of the data. . . . On the banks of the drainage ditches occur salt incrustations and these are in effect seepage deposits. They range in selenium content from 16 to 260 p. p. m. . . . These observations have a practical aspect aside from their scientific interest, in that they indicate clearly the possibility of improvement of seleniferous land by irrigation and drainage where such management is practicable."

Interfacial energy and the molecular structure of organic compounds.—III, The effect of organic structure on absorbability, E. R. Linner and R. A. Gortner (*Jour. Phys. Chem., 39 (1935), No. 1, pp. 35–67, figs. 13; abs. in Minnesota Sta. Rpt. 1935, pp. 27–29*).—The experiments here reported (E. S. R., 73, p. 740) were carried out at the Minnesota Experiment Station in order to elucidate the effect of substituent groups on adsorption. Adsorption studies were carried out with a series of structurally related compounds on a single and comparable substrate. For this study a large sample of decolorizing carbon, norite, was used. Members of the homologous series of fatty acids used were formic, acetic, propionic, butyric, valeric, caproic, and caprylic acids; members of the homologous series of dicarboxylic acids used were oxalic, malonic, succinic, glutaric, and adipic acids. To demonstrate the effect of various groupings in the molecules, compounds were chosen and adsorption studies made as follows: For the grouped chain, isobutyric, isovaleric, and methyl succinic acids; for the hydroxyl group, glycolic, lactic, glyceric, malic, and tartaric acids; for the carboxyl group, acids of the two homologous series listed above and citric acid; for aldehyde and keto groups, glyoxylic, pyruvic, and levulinic acids; for the double bond and variations due to cis- and trans-

isomers, fumaric, maleic, mesaconic, itaconic, and citraconic acids; and for halogen substitutions mono- and di-bromosuccinic acids.

Generalizations and conclusions drawn by means of various well-known physicochemical equations from the data obtained are also shown.

Electrokinetics.—XIV, A critical comparison of electrophoresis, streaming potential, and electrosmosis, H. B. BULL (*Jour. Phys. Chem., 39 (1935), No. 5, pp. 577–583, fig. 1; abs. in Minnesota Sta. Rpt. 1935, p. 24*).—This contribution from the Minnesota Experiment Station (E. S. R., 73, p. 740) describes a new electrophoretic cell and reports experiments in which the electrophoretic, electrosmotic, and streaming potential methods of measuring the electrokinetic potentials were compared, with the use of the same solution and surface. "Good agreement was found when dealing with protein-coated surfaces. Poor correspondence was found between electrophoresis and streaming potential for quartz and cellulose surfaces."

Electrokinetics.—XV, The use of inert electrodes in measuring the streaming potential, H. B. BULL (*Jour. Amer. Chem. Soc., 57 (1935), No. 2, pp. 259, 260, fig. 1; abs. in Minnesota Sta. Rpt. 1935, p. 34*).—Continuing this series, the author compared reversible electrodes with nonreversible gold electrodes in the measurement of the streaming potential. The gold electrodes were found to give excellent values.

Investigations on the electrophoresis of cholesterol suspensions [trans. title], L. S. MOYER (*Biochem. Ztschr., 273 (1934), No. 1–3, pp. 122–131, figs. 2; abs. in Minnesota Sta. Rpt. 1935, p. 36*).—The author of this contribution from the Minnesota Experiment Station finds that cholesterol sols, prepared according to the various methods in the literature, show wide divergences in electrokinetic properties, and that the poor agreement of previous workers is to be explained by variations in methods of preparation, not by impurities in the cholesterol. Curves showing the behavior of cholesterol sols prepared by grinding in ice are given, the electrophoretic mobility being plotted against pH. Such curves were found to follow a Langmuir adsorption isotherm and to be best explained by the assumption of an adsorption mechanism as the cause of the ζ-potential of cholesterol suspensions.

Electrophoresis of sterols.—II, Ergosterol, L. S. MOYER (*Jour. Gen. Physiol., 18 (1935), No. 5, pp. 749–753, fig. 1; abs. in Minnesota Sta. Rpt. 1935, p. 45*).—This contribution from the Minnesota Experiment Station, apparently an extension of the paper noted above, takes up the electrophoretic behavior of powdered ergosterol crystals, which was found to be identical with that previously found for cholesterol, within the limits of experimental error. Both sterols were found to have an isoelectric point at pH 3.1. Evidence for an adsorption hypothesis is presented to explain this phenomenon.

The dissimilation of pyruvic acid by Lactobacillus lycopersici, M. E. NELSON and C. H. WERKMAN (*Iowa State Col. Jour. Sci., 10 (1936), No. 2, pp. 141–144*).—Pyruvic acid was found to be fermented by *L. lycopersici* with the production of lactic, acetic, and carbonic acids in equimolecular quantities. One molecule of pyruvic acid undergoes oxidation to acetic and carbonic acids with the simultaneous reduction of a second molecule of pyruvic to lactic acid.

Preparation of white zein from yellow corn, I. D. MASON and L. S. PALMER (*Jour. Biol. Chem., 107 (1934), No. 1, pp. 131, 132; abs. in Minnesota Sta. Rpt. 1935, p. 37*).—Noting that it has not been possible previously to prepare a white zein from yellow corn, the authors of this contribution from the Minnesota Experiment Station report experiments in which a method was worked out whereby perfectly white, pure zein, the principal protein in corn, was prepared from yellow commercial corn gluten meal. The essential new features in the

method consisted in rendering the yellow alcoholic solution of the zein colorless by shaking it with ethylene dichloride in a separatory funnel.

The nature of the pigments of the gasoline extract of wheat, M. C. MARKLEY and C. H. BAILEY (*Cereal Chem., 12 (1935), No. 1, pp. 33–39, figs. 3; abs. in Minnesota Sta. Rpt. 1935, p. 26*).—By means of a modified method, elaborated at the Minnesota Experiment Station, for the separation of the carotenoid pigments by utilizing the differences in the solubilities of carotene and of xanthophyll in hydrocarbons and in aqueous alcohol, "it was found", according to the abstract, "that approximately 95 percent of the pigmentation of the gasoline extract of wheat was due to carotenoid pigments. These carotenoid pigments were found by spectral analysis to be carotene and xanthophyll with no lycopene present. Xanthophyll was found to be the predominating pigment, since it constituted from 65 to 87 percent of the total carotenoid pigments. A number of noncarotenoid pigments as yet unidentified were found in small quantities in the gasoline extract."

The pigments of the dilute alcohol or acetone extract of whole wheat meal, M. C. MARKLEY and C. H. BAILEY (*Cereal Chem., 12 (1935), No. 1, pp. 40–48, figs. 3; abs. in Minnesota Sta. Rpt. 1935, p. 29*).—It was found in an investigation carried out at the Minnesota Experiment Station that upon extracting ground wheat or flour with aqueous alcohol or acetone, extracts which had properties similar to those of the flavones which have been extracted from wheat leaves were obtained. According to the abstract, "these extracts have indicator properties, being pale yellow in neutral or acidic media and intense greenish or brownish yellow in alkaline media. The adsorption spectra of both the neutral and alkaline aqueous alcohol extract of durum wheat was determined in both the visible and the ultraviolet regions. These pigments were found in increasing amounts as the refinement of the flour decreased, indicating a possible location in the fibrous portions of the wheat berry. However, they appear to be distinct from the brownish pigment of the bran of 'red' wheats. Some dark-colored extracts were obtained from wheat by prolonged (2 yr.) extraction with alkaline media."

Determination of the carotenoid pigment concentration of small samples of whole wheat, M. C. MARKLEY and C. H. BAILEY (*Cereal Chem., 12 (1935), No. 1, pp. 49–53, fig. 1; abs. in Minnesota Sta. Rpt. 1935, p. 27*).—Adaptations of method devised at the Minnesota Experiment Station permitted an analysis of the pigments contained in the seed from a single plant of wheat.

According to the abstract, "by the use of special technic it was possible to determine the carotenoid pigment concentration of samples of wheat as small as 0.55 g. The errors in this determination were studied and from replicated tests were found to be represented by a coefficient of variability of 7. This indicates that the method would be sufficiently precise for use in inheritance studies involving the pigmentation of cereal grains."

Factors affecting the diastatic activity of wheat flour, [I], II (*Cereal Chem., 11 (1934), No. 5, pp. 515–522, fig. 1; 12 (1935), No. 3, pp. 268–275; abs. in Minnesota Sta. Rpt. 1935, pp. 23, 24, 34*).—This investigation was carried out at the Minnesota Experiment Station.

In the first paper, by M. C. Markley and C. H. Bailey, it was found "that the substitution of 16XX silk for 10XX silk on the patent sifter of an experimental mill, with the consequent reduction in particle size, increased the diastatic activity of the patent flour by 42 percent when the milling was done at moderate atmospheric humidities (50 percent), but when the relative humidity was increased to 75 percent the increase in diastatic activity due to the finer particle size was only 9 percent. This indicates that granulation is

probably not the principal factor, but that the condition of the surface of the starch granules is of major importance in determining the diastatic activity of a flour.

"The diastatic activity of flour is affected by the tempering of the wheat. When wheat was moistened with water and placed in a closed can for several days, the diastatic activity of the flour was much lower than when the dry wheat was exposed to humid air until the moisture content was appreciably increased. A short temper just prior to milling was of little effect.

"The environment under which the wheat was grown had an effect upon the diastatic activity of the resulting flour. Marquis wheat was found to yield flour 40 percent higher in certain localities than in others during the 1933 crop season. The variety of wheat was also found to be a factor in the diastatic activity of the finished flour. For example, Ceres wheat was found to be significantly higher in diastatic activity in the flour than was Marquis.

"The diastatic activity of flour was found to be correlated with the diastatic activity of the ground whole wheat. The magnitude of this correlation was affected by many factors, namely, varietal influences, environmental influences during the growing, harvesting, and storage of the wheat, and environmental influences involved in the milling technics used for producing both the white flour and the whole wheat meal."

The second paper, by W. R. Steller, M. C. Markley, and C. H. Bailey, gave the results of determining the relative diastatic activity of 19 samples of flour milled from blends of equal quantities of wheat grown during 1933 in the rod row nurseries at each of three locations in Minnesota, used in order to eliminate climatic and soil effects. Blended samples of patent flour, and with nearly the same reliability the blended wheat samples, were found to be as satisfactory a method for the determination of the relative diastatic activity of different wheat varieties as individual sample determinations, if sound, ungerminated wheat samples were used. It was noted that 70 percent of the sugar formed during a 60-min. digestion was converted during the first 15 min. and 83 percent during the first 30 min. Extending the digestion period for another half hour resulted in an average increase of only 9 percent over the first half hour. The digestion period could, therefore, be shortened to 30 min. without serious loss of accuracy. An abundance of saccharifying or beta-amylase was present in all samples. In the enzymic conversion of starch to sugar a limiting factor was found which was associated with starch and which was removed by prolonged dialysis.

Biochemical studies in the nitrogen metabolism of the apple fruit.—I, The estimation of amino-nitrogen by the Van Slyke method in presence of tannin, A. C. HULME (*Biochem. Jour., 29 (1935), No. 2, pp. 263–271, fig. 1*).—The abnormally high figures for the amino nitrogen content of apple fruits as obtained by the Van Slyke method were thought to be due to tannin. Experiments indicated that complete removal of small amounts of tannic acid added to apple extracts could be achieved by precipitation with potassium dichromate, and presumably any present in the extracts themselves is removed by this method, which is shown not to interfere with the amino or acid amide groups.

Based on the above result, a method is described whereby the interference of small amounts of tannin with the Van Slyke amino nitrogen determination is entirely overcome, and tentative suggestions are made for a new method of determining the tannin content of plant extracts.

The acid degradation of wool keratin, M. BARR and R. EDGAR (*Iowa State Col. Jour. Sci., 10 (1936), No. 2, pp. 129–134, figs. 2*).—The degradation of wool

keratin by from 0.25 to 7.87 N hydrochloric acid in 10 hr. at 25° C. and by from 0.25 to 0.75 N hydrochloric acid and from 0.06 to 0.70 N sodium chloride in 1 hr. at 100° was followed by means of determinations of the weight, nitrogen, sulfur, and wet breaking strength of the residual keratin. Acid degradation, much greater at 100° than at 25°, was shown to remove little of the sulfur of wool, to decrease its nitrogen approximately in proportion to its weight, "and to have a sensitive indicator in wet breaking strength." The residual wool was shown to decrease in nitrogen content and increase in sulfur content slowly with increasing concentration of acid.

The acid and alkaline degradation of chlorinated wool, F. and M. BARR and R. EDGAR (*Iowa State Col. Jour. Sci., 10 (1936), No. 2, pp. 145–150, figs. 3*).—At the Iowa Experiment Station the degradation of wool, chlorinated by 0.06 N hypochlorous acid in 1 hr. at 25° C., by from 0.5 to 6 N hypochloric acid in 10 hr. at 25°, from 0.25 to 0.75 N hydrochloric acid in 1 hr. at 100°, and from 0.05 to 0.2 N sodium hydroxide in 10 hr. at 40°, was followed by determining the weight, nitrogen, sulfur, and wet breaking strength of the residual wool.

"Degradation of chlorinated wool by acid in 10 hr. at 25° exceeded that of wool as measured by sulfur or wet strength. At 100° the loss in sulfur was greater than that in weight, nitrogen, or wet strength. Sodium hydroxide in 10 hr. at 40° dissolved the same amount of sulfur from chlorinated wool as from wool but decreased the nitrogen and weight of the chlorinated wool more. The wet strength of chlorinated wool was completely destroyed in 1 hr. at 40° by 0.05 N sodium hydroxide. The residual chlorinated wool has been shown to decrease in nitrogen and sulfur with increasing concentration of acid or alkali."

Effect of sulphur sprays on corrosion of prune cans, E. H. WIEGAND (*Canning Age, 17 (1936), No. 2, pp. 72–74, 89, 90, figs. 8*).—A contribution from the Oregon State College gives a semipopular outline of work in which for all types of tins the effect of sulfur spraying of the fruit in reducing the degree of vacuum in the tins was greatest in the case of thiosulfates. Sulfites and elementary sulfur showed a less marked effect. The type of container also affected the results.

An improved liquid absorption tube, W. D. TURNER (*Indus. and Engin. Chem., Analyt. Ed., 7 (1935), No. 6, p. 444, fig. 1*).—This new unit "consists of the solid absorption tube, to which has been added the familiar Friedrichs gas absorption principle, in the form of a helical coil. This unit possesses all the advantages of the original dry absorber, besides offering a contact path of some 42 cm in length between the gas bubbles and the liquid absorbing medium." Further advantages of the apparatus are enumerated. A dimensioned constructional diagram accompanies the note.

Improvements in design of pressure control assembly, S. PALKIN (*Indus. and Engin. Chem., Analyt. Ed., 7 (1935), No. 6, p. 436, fig. 1*).—In a contribution from the Bureau of Chemistry and Soils, U. S. D. A., the author describes and illustrates an assembly in which pressure control is simplified with respect to manipulative detail by placing parts of the operation under automatic control.

A precision oil gage, S. PALKIN (*Indus. and Engin. Chem., Analyt. Ed., 7 (1935), No. 6, pp. 434, 435, fig. 1*).—Of the apparatus described in this contribution from the Bureau of Chemistry and Soils, U. S. D. A., the author states in part that "the gage is in effect a double U-tube type manometer in which both oil and mercury are employed, the latter serving, however, only as a mobile 'backing' medium for the oil column." Pressure changes of 0.033 mm of mercury could be read accurately.

Continuous production of distilled water free from carbon dioxide and ammonia, F. G. STRAUB (*Indus. and Engin. Chem., Analyt. Ed., 7 (1935), No. 6,*

pp. 433, 434, figs. 2).—A brief contribution from the University of Illinois describes various stages of experimentation whereby a still yielding a distillate from tap water of a specific conductance of 5×10^{-6} reciprocal ohms was made to yield 9 l per hour of a distillate the pH value of which was 6.8 and the specific conductance 0.3×10^{-6} reciprocal ohms. A small quantity of a dilute solution of sulfuric acid and sodium chromate was added continuously with the main feed of condensed steam, and air, free from carbon dioxide and ammonia, was blown through the still.

The determination of soil moisture by means of the carbide method [trans. title], W. Sibirsky (*3 Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 10–13*).—The author describes an apparatus which consists mainly of an ebonite cylinder containing an inner aluminum cylinder and closed by a cone-shaped cap in which a perforated ebonite plate covered by a disk of blotting paper supports a charge of calcium carbide sufficient to prevent any loss of moisture with the gas leaving the apparatus. The conical cap is provided with an exit tube closed by a Bunsen valve which is in turn protected against mechanical damage by a cap. The aluminum cylinder contains two steel balls. Powdered carbide is placed in the bottom of the aluminum cylinder in a quantity amounting to about three times the weight of the sample, and the apparatus is closed and weighed. The soil sample is placed upon a part provided for that purpose at the top of the aluminum cylinder, and the apparatus is again closed, weighed (to an accuracy of about 0.02 g), the apparatus is shaken for 5 min. by hand or by machine, it is again weighed, and the difference in weight, multiplied by the factor 1.47, is taken as the moisture content of the sample.

The author considers that, in view of the rapid oxidation of soil organic matter at 105° C. and the appreciable oxidation occurring at temperatures even as low as 50°, the carbide method gives the more dependable results.

Is the alcohol method for determining the water content in soils reliable? L. C. Smolík (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 13, 14*).—In comparisons involving several hundred determinations, the author found a considerable number of samples giving results by the alcohol method very different from those given by the ordinary procedure, so that he concluded that "the alcohol method cannot be looked upon as reliable." He points out that "it is also very interesting that this difference is not correlated with the nature of the horizons of soil types or with the amount of organic matter.

"Out of 813 determinations [arithmetical means of 2 or 3 analyses], 38, i. e., about 5 percent, showed difference up to 28 relative percent—in some cases the alcohol method gave higher, in the other cases lower results than the ordinary method. Out of 813 samples, 10 soils gave more water by alcohol than by oven drying."

Determination of the phosphate and potash needs of soils by chemical analysis, E. Truog and L. A. Dean (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 106–108*).—A brief discussion contributed from the University of Wisconsin calls attention to the fact that "a terminology which divides the soil phosphorus into an available portion and an unavailable portion is neither logical nor conducive to clear thinking", since all forms of soil phosphorus have an appreciable degree of availability to plants. It is suggested that it would be better to call that portion which can be dissolved easily by a single extraction with a weak solvent as being readily available, and that portion which continues to be dissolved by successive extractions as being slowly available. Also, "in setting up the minimum

levels of adequacy of readily available plant nutrients it should always be recognized that these are influenced by many factors. First, there is the crop factor—as it [is] generally known, certain crops require higher levels, especially of certain nutrients; crops having a very long growing period like sugarcane may make a satisfactory growth when forced to feed entirely on slowly available phosphate, while, under the same conditions, maize in northern United States and wheat in Canada might not make a satisfactory growth. Second, there is the climatic and seasonal factor—the shorter and colder the growing season the higher is the level needed for most nutrients; also a high proportion of cloudy weather during the growing season tends to raise the level of readily available potash needed. There is also a subsoil factor—while most agricultural plants feed largely in the plowed surface layer, deep rooted plants like alfalfa and sweetclover are able to feed vigorously to a depth of 4 or 5 ft. (1.2–1.5 m), and hence the subsoil must be given consideration in certain cases. And, finally, there is the economic factor—when land and agricultural products are high in price, it is profitable to farm at higher levels of readily available plant nutrients than when the reverse is true."

The simultaneous estimation of active chemical factors in plant nutrition through tests of a sodium acetate-acetic acid soil extract, M. F. MORGAN *(3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 103–105).*—This contribution from the Connecticut [New Haven] Experiment Station presents in condensed outline the methods for determining important soil constituents in solutions obtained by means of the author's Universal soil extracting solution and series of colorimetric and turbidimetric estimations (E. S. R., 67, p. 105). Attention is directed to the fact that "in most cases only one drop of a reagent of suitable concentration is sufficient to produce a readable test within 1 or 2 min. Using the above technic it is possible for one operator to make the entire series of tests on as many as 72 soils in a working day."

Report on vitamin A: Determinations with the Hilger vitameter, F. W. IRISH *(Jour. Assoc. Off. Agr. Chem., 19 (1936), No. 2, pp. 244–248).*—The Hilger vitameter is a modified spectrophotometer designed to measure the amount of absorption of ultraviolet light of the wave length of 3,280 a. u. The mechanism of the instrument is described. The amount of absorption at this wave length has been used to measure the potency of vitamin A concentrates, as noted previously (E. S. R., 60, p. 689). To check the procedure and calculations proposed by the instrument maker, 8 collaborators determined the units of vitamin A in 5 samples of cod-liver oil of known potency by strict compliance with the specified manipulations and calculations, by modifications introduced by the collaborator, and by calibration of the vitameter against U. S. Pharmacopoeia reference cod-liver oil. Results obtained from the use of this instrument by the different collaborators deviated considerably from the average for each oil and were not sufficiently concordant to warrant its immediate recommendation as an Official method.

Studies of crystalline vitamin B_1, II, III *(Jour. Amer. Chem. Soc., 57 (1935), No. 3, pp. 517–520, figs. 2; 536, 537).*—The scope of the work recorded in the first paper of this series (E. S. R., 73, p. 437) is extended.

II. *Elementary composition and ultraviolet absorption,* O. Wintersteiner, R. R. Williams, and A. E. Ruehle.—The authors show results in the carbon determination considerably higher than those obtained by others—average 42.75 percent. They point out the considerable difficulty encountered in securing consistent nitrogen determinations, giving 16.26 percent as their average figure. Their

average percentage of hydrogen being 5.35, of sulfur 9.51, and of chlorine 20 88, they find their results to agree best with the formula $C_{12}H_{16}ON_4S\ 2HCl$ for the hydrochloride analyzed (the theoretical percentages being C 42.71, H 5.38, N. 16.62, S. 9.51, and Cl 21.03).

Ultraviolet absorption was found to occur in two bands, at 235 mμ and at 267 mμ, respectively.

III. *Cleavage of vitamin with sulfite*, R. R. Williams, R. E. Waterman, J. C. Keresztesy, and E. R. Buchman.—"Vitamin B_1 is split quantitatively at room temperature by sulfite at pH 5 into two products having the compositions $C_6H_8N_2SO_3$ (I) and C_6H_8NSO (II), respectively. I is a sparingly double acidic product. II is a chloroform soluble base which has been isolated in the form of a crystalline hydrochloride."

An enzymic method for the estimation of true vitamin C, H. Tauber and I. S. Kleiner (*Jour. Biol. Chem., 110 (1935), No. 3, pp. 559–563*).—The authors devised a method for estimating true vitamin C content by determining the reducing power by indophenol titration of a food extract before and after the action of the specific ascorbic acid oxidase isolated by them (E. S. R., 74, p. 442) The technic was applied to oranges, lemons, tangerines, grapefruit, beer, tea, and milk. Certain tissue extracts containing interfering substances were purified with mercuric acetate. The oxidase was prepared by extracting the edible portion of Hubbard or summer squash with 30 percent alcohol.

The interfering action of glutathione in the silver nitrate test for ascorbic acid, J. L. Svirbely (*Biochem. Jour., 29 (1935), No. 7, pp. 1547–1551*).—Experimental results are reported indicating that the silver nitrate reduction test for ascorbic acid depends upon the relative amounts of glutathione and ascorbic acid associated with one another in certain animal organs or extracts and the pH of the silver nitrate. The color ranged in an alkaline medium from yellow to brown to black, depending on the concentrations of the two substances. Failure of the test did not indicate lack of ascorbic acid, but that the content was too low in comparison to glutathione to give a positive reaction. The test was found to be better for qualitative than quantitative analysis.

Reductions of pure ascorbic acid solutions were made in test tubes with acid and alkaline silver nitrate solutions. This method was sensitive to 0.003 mg ascorbic acid in the alkaline solution. It required 0.3 mg ascorbic acid to reduce the acid silver nitrate, pH about 3, in 45 min.

Gold sols formed immediately when ascorbic acid was added to gold chloride without applying heat. The color ranged from purplish-red to deep blood-red, depending upon the amount of ascorbic acid present. The addition of glutathione or cystine to the gold chloride caused the yellow color to disappear, indicating that stable salts formed which prevented the reduction of ascorbic acid. The formation of sols was sensitive to 0.045 mg ascorbic acid.

Determination of reduced ascorbic acid in small amounts of blood, C. J. Farmer and A. F. Abt (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 2, pp. 146–150, fig. 1*).—A micromethod for determining reduced ascorbic acid in small amounts of blood is described. A 0.3-cc sample of blood is deproteinized with metaphosphoric acid solution. The reduced ascorbic acid in the plasma is then titrated with a standardized solution of sodium 2,6-dichlorobenzenoneindophenol. The apparatus used for the determination is described and illustrated.

This method, because of the minute amount of blood required, is recommended in preference to the one previously described (E. S. R., 74, p. 135) in working with infants and in making repeated observations on the same individual.

Determination of chlorine in organic compounds.—I, A rapid lamp method, W. M. MALISOFF (*Indus. and Engin. Chem., Analyt. Ed., 7 (1935), No. 6, p. 428*).—In this method the organic compound is dissolved in a combustible solvent in various concentrations, preferably to produce from 0.2 to 0.3 percent chlorine, and is burned in the standard sulfur lamp following the precautions officially recommended by the American Society for Testing Materials. The titrations are made with precisely the reagents specified by the method with the same indicator. About 1 g of solution is burned. The standard calculation may be used and a correction applied, 1 percent of sulfur being equivalent to 2.216 percent of chlorine.

"The choice of a hydrocarbon solvent should fall on a petroleum fraction relatively free of sulfur and somewhat lighter than gasoline. The material used in this investigation contained 0.018 percent sulfur. . . . The lamp method operates best in solutions less concentrated than 0.5 percent, preferably at the 0.1- to 0.3-percent level, where the determinations are good to 2 to 3 percent. Therefore, since burning about 1 g suffices, a determination can be carried out with only a few milligrams of a substance."

Determination of acetylmethylcarbinol in fermentation liquors, G. L. STAHLY and C. H. WERKMAN (*Iowa State Col. Jour. Sci., 10 (1936), No. 2, pp. 205–211*).—At the Iowa Experiment Station commercial acetylmethylcarbinol was purified by washing with anhydrous diethyl ether and filtering; 1 mol of acetylmethylcarbinol, when subjected to oxidation with $K_2Cr_2O_7+H_3PO_4$ yielded 2 mols of acetic acid; in the periodate oxidation for 2,3-butylene glycol, 1 mol of the carbinol formed 1 mol of acetaldehyde; and acetylmethylcarbinol reduced the Fehling solution, for which reason, in a reducing sugar determination, the cuprous oxide precipitated by the carbinol must be subtracted from the total cuprous oxide to obtain that due to the sugar.

Preliminary observations on the mellowing and stabilization of wine, M. A. JOSLYN (*Fruit Prod. Jour. and Amer. Vinegar Indus., 15 (1935), No. 1, pp. 10–12, 24*).—This contribution from the University of California deals with the following topics: Clarification and stabilization of wines by freezing, rapid aging, or "mellowing"—preliminary observations on the nature of the changes involved, preliminary tests with dry wines, comparison of the effectiveness of oak extract, role of acetaldehyde and peroxide oxidation, and preliminary tests on aging sherry.

Studies on the alkaline pulping processes, S. I. ARONOVSKY (*Paper Indus., 16 (1934), No. 6, pp. 413–419*).—This is a summary of the author's series of papers on the cooking process (E. S. R., 73, p. 743), bringing together in the eight tables accompanying the present paper the principal results of the studies on various pulping reagents and outlining the methods used in the experiments on sodium sulfate, sulfite, thiosulfate, sulfide, bromide, phosphate, carbonate, and hydroxide.

AGRICULTURAL METEOROLOGY

Report of the Chief of the Weather Bureau, 1934–35 (*U. S. Dept. Agr., Weather Bur. Rpt. 1935, pp. III+161, pls. 4*).—This report, like previous reports (E. S. R., 73, p. 155), gives a brief administrative review of activities of the Weather Bureau during the year, a general summary of weather conditions of each month of 1934, brief summaries of data regarding tornadoes, hail, losses from windstorms, sunshine, and excessive rainfall during the year, and detailed tabulations of data for pressure, temperature, precipitation, humidity, cloudiness, wind, and evaporation throughout the United States.

Comparing the weather of 1935 with that of 1934, the report says: "The severe and unprecedented drought of 1934, which seriously affected agriculture in the United States, did not carry over to an appreciable extent into the 1935 crop-growing season. Following the extremely hot, dry summer of last year, the fall months brought timely rains which produced soil moisture sufficient to permit the seeding and to promote the early growth of winter grains in practically all sections from the Great Plains eastward, except in the southwestern plains where moisture continued insufficient. In the western mountains, the winter months had much heavier snowfall than during the preceding winter, assuring a better water supply for irrigation than was available for the summer of 1934. Thus, except in the southwestern plains, the crop-growing season of 1935 began under much more favorable conditions than that of 1934."

Report of the Chief of the Weather Bureau, 1935, W. R. GREGG (U. S. *Dept. Agr., Weather Bur. Rpt. 1935, pp. 13*).—This is a brief administrative account of the work of the Weather Bureau during the fiscal year ended June 30, 1935, dealing briefly with cooperation with other nations, departments, and bureaus in meteorological service; weather conditions in 1935 as compared with 1934; air-mass analysis and its practical applications; airplane observations and their use in forecasting; reorganization of activities at airport stations and in the airway service; reorganization of the hurricane-warning service; improvements in flood forecasting; work in marine meteorology; and the fire-weather service.

Monthly Weather Review, [March–April 1936] (*U. S. Mo. Weather Rev., 64 (1936), Nos. 3, pp. 69–103, pls. 14, figs. 20; 4, pp. 105–158, pls. 10, figs. 20*).—In addition to the usual detailed summaries of climatological data, solar and aerological observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

No. 3.—Determination of Altitudes from the Adiabatic Chart and the Refsdal Aerogram, by P. J. Kiefer (pp. 69–71); Variability Isocrymal Maps for the Great Plains, by E. E. Lackey (pp. 71–76); Intercorrelations between Climatic Variables in the Corn Belt, by J. K. Rose (pp. 76–82) (see below); An Observation of Unusual Ice Crystals, by C. R. Elford (p. 83); Monthly Temperatures, 1925–35, at the Montezuma Station of the Smithsonian Institution, by C. P. Butler (p. 83); Erratum in the Smithsonian Meteorological Tables: Temperature Correction Factor in the Hypsometric Formula (English Measures), by V. E. Jakl (pp. 84, 85); Composition and Origin of Dust in the Fall of Brown Snow, New Hampshire and Vermont, February 24, 1936, by W. O. Robinson (p. 86); Meteorological History of the Brown Snowfall of February 1936, by H. R. Byers (pp. 86, 87); and Duststorms of February and March 1936 in the United States, by R. J. Martin (pp. 87, 88).

No. 4.—On the Relation between Rainfall and Stream Flow—II, by R. T. Zoch (pp. 105–121); Cooling in the Lower Atmosphere and the Structure of Polar Continental Air, by H. Wexler (pp. 122–136); and Duststorms in the United States, April 1936, by R. J. Martin (p. 137).

Meteorological tables, D. A. SEELEY, A. E. WHITE, and H. M. WILLS (*Mich. State Bd. Agr., Ann. Rpt. Sec., 74 (1935), pp. 137–150*).—Data corresponding to those previously noted (E. S. R., 73, p. 444) are reported for the year ended June 30, 1935.

Intercorrelations between climatic variables in the Corn Belt, J. K. ROSE (*U. S. Mo. Weather Rev., 64 (1936), No. 3, pp. 76–82, figs. 7*).—A study is reported which "reveals that rainfall and accumulated temperatures, of the same month and of successive months, correlate to significant extents in parts of the Ameri-

can Corn Belt; and moreover, that the distribution of the areas of significant correlation reveals problems which invite further research that may yield highly important results."

Influence of annual temperature variation on precipitation and the weather [trans. title], L. LYSGAARD (*Met. Ztschr. [Braunschweig], 53 (1936), No. 3, p. 108*).—This article discusses briefly and attempts to evaluate the relation in Denmark of rising temperature and diminishing rainfall in spring and summer to falling temperature and increasing rainfall in autumn.

Origin of warm waves [trans. title], E. DINIES (*Met. Ztschr. [Braunschweig], 53 (1936), No. 3, pp. 81–84, figs. 4*).—It is indicated that winter warm waves in Middle Europe have their origin in highs in the Azores and on the American Pacific coast.

Soil temperatures at Bozeman, Montana, during sub-zero weather, G. A. MAIL (*Science, 83 (1936), No. 2163, p. 574*).—During a period, beginning January 25, 1936, of the coldest and most extended sub-zero weather ever recorded at Bozeman, Mont., the frost line reached 3 ft. in the soil and remained there 23 days. The minimum temperature at the surface of the soil, which was covered with 8 to 15 in. of snow, was —7° C., while the minimum air temperature was —41.7°, thus showing the great insulating effect of snow cover.

Droughts of 1930–34, J. C. HOYT (*U. S. Geol. Survey, Water-Supply Paper 680 (1936), pp. VII+106, pl. 1, figs. 69*).—This report is based on information collected by various Federal and State agencies. It summarizes "some of the more outstanding questions related to droughts, both physical and economic. It outlines the nature and extent of the droughts of 1930–34; compares them with past dry periods in terms of precipitation, run-off, ground water, evaporation, and transpiration; and sketches the effects of droughts on water supplies as related to a variety of human purposes, including agriculture, domestic and industrial uses, health, power, navigation, and recreation and wild life; it also touches upon the relief, political, and economic elements."

It is stated that while nothing can be done to modify the occurrence of droughts, "the economic losses resulting from shortages of water caused by droughts relate to activities that man can control, and it is possible for man to do much toward the alleviation of such losses by the conservation of available water supplies by storage, by efficiency in all uses of water, and by the adjustment of activities that depend upon water to available supplies and to variations in supplies."

SOILS—FERTILIZERS

[Soil and fertilizer studies by the Florida Station] (*Florida Sta. Rpt. 1935, pp. 61, 62, 63, 112–114, 114, 115, 126–128*).—Data are given on the effect of green manures on the composition of the soil, soil moisture studies in relationship to cover crops, and phytometer studies on the comparative rate of decomposition of *Crotalaria striata, C. spectabilis,* and *C. intermedia,* all by R. M. Barnette; the behavior of zinc in soils, by H. W. Jones; the effect of water control on peat and muck soils, by R. V. Allison and B. S. Clayton; the role of copper, manganese, and zinc in peat and muck soils of the Everglades, by Allison, J. R. Neller, and R. E. Robertson; and phosphorus requirements of sugarcane and various grasses on Everglades soils, composition of subsurface waters, chlorine and nitrogen content of soils, oxidation, and effects of green manures, all by Neller.

[Soil and fertilizer investigations by the Idaho Station] (*Idaho Sta. Bul. 220 (1936), pp. 8, 9, 49*).—Brief notes are given on the use of gypsum for the

amelioration of slick spots in soils, potash and nitrogen content of soils from new areas in the State, and rock phosphate v. superphosphate in southern Idaho.

[Soil and fertilizer studies by the Michigan Station], C. S. BRYAN and C. E. MILLER (*Michigan Sta. Rpt. 1935, pp. 180, 235, 236*).—Notes are given on the reproduction of soil bacteria in soils stored at 25° and 7° C., treatment of muck soils with sulfur and salt, fertilizer trials on soils in the Upper and Lower Peninsulas, the phosphorus content of alfalfa, and the unproductiveness of subsoils.

[Soil and fertilizer studies by the New Jersey Stations] (*New Jersey Stas. Rpt. 1935, pp. 85–88*).—Results are briefly noted on studies of availability of nitrogenous fertilizers; lime and soil improvement investigations; phosphorus content of New Jersey soils and its availability; lysimeter, base exchange, and soil profile studies; and the mechanism of humus formation.

Soil sampling tubes for shallow depths, F. HEYWARD (*Soil Sci., 41 (1936), No. 5, pp. 357–360, fig. 1*).—Fully dimensioned working drawings, descriptions, and directions for use are given for three distinct types of sampling tubes designed at the U. S. D. A. Southern Forest Experiment Station. The first of these devices is a tube for collecting samples for moisture determination of the 0- to 7-in. soil depth, the second is a tube for collecting a large number of cores in undisturbed field condition from the 0- to 6-in. soil depth of a size large enough to grow tree seedlings, and the third is a tube for obtaining a large number of samples of constant volume from the 0- to 3-in. soil depth.

A direct method of aggregate analysis of soils and a study of the physical nature of erosion losses, R. E. YODER (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 337–351, figs. 5*).—The "inherent weaknesses" of the elutriation method of aggregate analysis are pointed out, and the use of this method of aggregate analysis is questioned; a mechanism is devised to account for the slaking reaction of soils in the presence of excess water; and a method and apparatus for determining the water-stable aggregate distribution in soils are reported.

"Several soils of the Cecil series with widely varying clay contents were found to have similar distribution of water-stable aggregates. Soils from different series were found to be characterized by different distributions of water-stable aggregates."

The physical nature of the erosion process was studied on controlled field plats of Cecil clay located on several slopes. The losses from this "strongly aggregated" soil were found to occur primarily in the form of water-stable aggregates.

Data presented to show the effectiveness of winter legumes in controlling sheet-erosion losses are included, and the manner in which this type of "vegetative control" functions is reviewed. Results of the use of various widths of strip crop for controlling sheet erosion are presented. "The basic weakness of this type of vegetative control practice" is pointed out.

Field textures and physical composition determined by two methods of mechanical analysis, C. F. SHAW (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 42–46, fig. 1*).—In an investigation carried out at the University of California, using as the two mechanical analysis procedures the ammonia-centrifuge method and a modification of the International method, 64 samples of surface soils from the Lodi and Napa soil survey areas, which had been surveyed by the same two men, working together, were analyzed. To make the comparisons direct, the upper limit of the silt fraction was held at 50μ and of the clay at 5μ in both methods.

From these studies it became apparent that from the standpoint of mechanical analysis the field men were inclined to name the soils of intermediate tex-

tures in one grade too coarse, light clay loams being judged as loams and light clays as clay loams. None of the so-called clay loams, however, fell far outside the clay loam portion of the triangular diagram, whereas several of the loams were well away from the loam section. The clays and sandy loams were consistently named. This "drift" in the judgment of textures appears to be due to a tendency to make the determination comparative. "When working in a region of dominantly heavy soils, the sandier soils are often named in a textural grade that is too light or coarse, whereas in a region of dominantly sandy soils many soils of finer texture are often designated by a grade heavier or finer than their composition would warrant."

Of the dispersion methods used it is noted that "field texture expresses not the actual or ultimate texture of the soil but rather a combination of texture and of the structure or degree of aggregation. The International method in its fundamental purpose aims to break down all structural aggregates and to resolve the soil into its individual particles. Since the structure of the soil depends to a considerable extent upon its chemical composition and on its exchangeable base status, the field texture cannot be expected to be directly reflected by the ultimate texture. Methods of mechanical analysis that are not sufficiently drastic to break down all of the aggregates but which resolve only the less stable aggregates into their ultimate particles will give a better measure of the mechanical composition of the field grades. It is very doubtful if mechanical analysis by the International method will permit an interpretation of textural grades on the basis of a triangular diagram or even in a three-dimensional figure.

"The drift of the analyses . . . would also indicate the grave difficulty in endeavoring to adjust mechanical analysis by the International method with the standards established by the ammonia-centrifuge method. . . . The marked difference in dispersion due to the use of ammonia in one method and the use of a sodium compound following severe pretreatment in the other makes such conversions of results thoroughly unsatisfactory. If a standardization of field texture is to be accomplished by means of the International method, it can only be done by accumulating several thousand analyses of soils whose textural grade has been determined in the field by men working in close cooperation and who have maintained consistent standards for their grade separations. In view of the tendency to drift toward lighter or heavier designations, as shown by the two men working in California, both of whom had years of experience in the field, consistence in textural designations can only be maintained by frequently checking textural judgment by comparing field samples with soils that have been selected as textural standards or by means of mechanical analyses that follow the method of dispersion by use of ammonia without pretreatment, by which the first textural standardizations were established."

Chemical composition of the colloids of the great soil groups, H. G. BYERS (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 76–79*).—In a contribution from the U. S. D. A. Bureau of Chemistry and Soils, the author points out that "in each group a representative soil series contains colloid material characteristic of the series and also of the great group to which the series belong. These characteristics may be brought into high relief by using the analytical data in the form of ratios calculated to express the relative chemical units of the analytical components, pseudo or real. The units used are for the most part the normal oxides of the elements silicon, aluminum, iron, calcium, magnesium, potassium, sodium, and hydrogen," and he gives some silica : sesquioxide, silica : alumina, and silica : total base ratios, together with

relative base-exchange capacities and combined water contents, in illustration of this point. He further notes that with increased data it becomes more and more apparent that "the colloids of each great group are characterized by the presence of a definite complex, or complexes, which are dissimilar in the different groups and essentially alike in each great group. Hence the existence in the field of these great groups." A hypothetical view of the nature of the process of soil genesis is developed on this basis.

Studies on Podzols and Brown forest soils, III, K. LUNDBLAD (*Soil Sci., 41 (1936), No. 5, pp. 383–394, figs. 3*).—The Podsol and Brown forest soil profiles previously dealt with (E. S. R., 75, p. 306) were investigated with respect to their capacity for dye absorption, experiments with artificial aluminosilicates showing that the dye adsorption is comparable to the ion adsorption of colloids.

"The adsorption of acid and basic dyes is a promising method for a rapid and conclusive investigation of the colloidal properties of a soil. . . .

"Methods such as those used in the three parts of this paper will permit a rapid and conclusive comparative study of the soil-forming processes in different soil regions. Acid oxalate determinations of the reactive part of the colloids or the easy methods of investigating the amphoteric properties of the soil colloids—especially determinations of the ultimate pH, the pH of exchange neutrality, the combining capacity at different pH values, and the adsorption of acid and basic dyes—are very valuable in comparative studies where many analyses are necessary. For a thorough knowledge of the soils total chemical analyses are necessary; for many purposes, however, they may be confined to a few type specimens of the soils and the comparative study made with the easy and rapid methods here applied."

Tensiometers for measuring the capillary tension of soil water, L. A. RICHARDS and W. GARDNER (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 352–358, figs. 3*).—Presented as a contribution from the Iowa and Utah Experiment Stations, a part of the work here recorded was carried out at Cornell University.

"The expression 'capillary tension' is used as a name for the negative pressure existing in the water in unsaturated soil, and porous cell-vacuum gage instruments used in its measurement are called tensiometers."

Principles underlying the use of indicating, recording, and differential tensiometers are discussed, and apparatus used by the authors is described.

The establishment of moisture equilibrium in soil, F. SHREVE and W. V. TURNAGE (*Soil Sci., 41 (1936), No. 5, pp. 351–355*).—In an investigation carried out by the Carnegie Institution of Washington at its Desert Laboratory at Tucson, Ariz., layers of soil of known moisture content were firmly tamped into large cans, two or three layers in each can, with differences of 5 or 10 percent between the contiguous layers. The soil, an alluvial clay or "adobe", with a water-holding capacity of 33.2 percent, was sampled in alternate months for 1 yr. and again at the end of the second year. In one of the four cans there was an approximation to equilibrium at the end of the second year, the extreme range of the readings being from 11.8 to 13 percent. In the other three cans a uniform distribution of moisture through the two or three layers was not attained.

"The change in distribution of the moisture during the first 2 mo. was greater than the total of all change in the subsequent 22 mo. in all cases but one. In some of the changes there is evidence of the influence of gravity. The individual layers of soil in a few cases showed the influence of an adjacent layer in the samples taken nearest it and a weaker influence in the sample or samples taken farther from it.

"The evidence of these results, and of those obtained in previous work on the natural moisture changes of soil in place, indicates that the movement at the low percentages prevailing in desert soils is very small, at least in heavy soils. The only rapid changes in moisture content are the increases due to heavy rainfall and the decreases at the surface by evaporation or at lower levels by root absorption. When low moisture contents are concerned and small differences of content are involved, the action of capillarity in the slow distribution of water through the soil and in the establishment of moisture equilibrium is of little importance."

The relation of crystal structure to base exchange and its bearing on base exchange in soils, W. P. KELLEY and H. JENNY (*Soil Sci., 41 (1936), No. 5, pp. 367–382, figs. 2*).—In a joint contribution from the Universities of California and Missouri the authors discuss conditions essential to ion exchange and present the results of experimental work on feldspars; zeolites and permutites; micas; talc; chlorites, pyroxenes, and amphiboles; pyrophyllite and kaolinite; bentonites and soil colloids; and on the exchange power of bentonites and soil colloids. They then take up the nature and strength of attraction forces and discuss other phases of the relation between crystal structure and base exchange. In part, their conclusions are that "it is highly probable that soil clays embrace a complex series of isomorphous minerals and that certain soils contain one general type of clay mineral, whereas other soils contain a second or a third type. The type actually predominating in a given mature soil would be expected to be that which is most stable under the conditions prevailing in that soil. On the other hand, it seems reasonable to suppose that immature soils might contain variable mixtures of clay minerals. At any rate, all of these clay minerals have more or less base-exchange power. It follows, then, that no one single substance is responsible for base exchange in all soils." Again pointing out that they "consider the views developed in this paper to be essentially tentative", the authors express the belief that "the OH of the lattice of clay minerals is an important source of their potential cation-exchange power, but it does not follow that the OH group is the sole cause of their exchange power. Should further investigation definitely establish that Al replaces Si in the clay minerals, and also that Mg replaces more or less Al, the negative charges thus introduced on the lattice would certainly necessitate the introduction of cations, and such cations would probably be potentially replaceable."

The relation between the physical properties of soils and the nature of the absorbed bases [trans. title], L. G. KOTZMANN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 24–26*).—The author examined the effects upon the stability of two soils produced by saturating them with the barium, calcium, magnesium, potassium, sodium, ammonium, and hydrogen ions, respectively. He gave particular attention to the Atterberg constants and mechanical compositions of the treated soils. The entirely different properties of the samples saturated, respectively, with univalent and with divalent bases were found to be especially striking. The soil saturated with the univalent bases, regardless of mechanical composition, formed no stable structural aggregates, the clods formed in the dry soil disintegrating completely when wetted. On the other hand, the clods formed from soil saturated with the divalent bases and the H ion were stable when wetted. Sodium-saturated soil had a distinctly lower rolling-out limit than had the corresponding calcium-saturated soil. The calcium-saturated soil also remained within the plasticity limits optimal for working for a longer time during drying out than did the sodium-saturated soil. In a series of soil preparations in which the absorbed sodium and calcium contents were varied from 0 to 100 percent of saturation,

the stability of aggregates, the plasticity limits, the capillary rise, and other physical properties were all markedly affected when the percentage of saturation with sodium reached from 4 to 5 percent. The effect of absorbed sodium steadily increased with increasing concentrations up to 30 percent of saturation, at which percentage the effect upon the physical properties of the soil was the same as that of complete sodium saturation.

Changes in exchangeable bases in soils as related to fertilizer applications, leaching, and crop removal, M. F. MORGAN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 70–72*).—In an investigation carried out at the Connecticut [New Haven] Experiment Station, four soils of different textural classes and varying in initial base content and degree of base saturation were each treated with sodium nitrate, ammonium sulfate, urea, and cottonseed meal at the rate of 200 lb. of nitrogen per acre per year over a 5-yr. period. The same quantities of phosphoric acid and potash were applied in all cases. The soils were in circular tanks containing a 7-in. depth of surface soil. No crops were grown on this series of tanks, but semiannual analyses of composites of the leachings were made during the 5 yr. At the beginning and end of the experiment determinations of the various exchangeable bases, total base-exchange capacity, and degree of base saturation were made. One of the above soils was also studied in tanks with subsoil to a depth of 18 in. under annual cropping with tobacco.

Leachings from the sodium nitrate treatments contained most of the sodium applied in the fertilizer. Exchangeable sodium increased slightly, in proportion to the base-exchange capacities of the soils, but there was a minimum of losses of other bases in comparison with the other three forms of nitrogen. Much of the potassium applied in the fertilizer was conserved by the soil in the exchangeable form. In all cases there were increases in exchangeable potassium, in proportion to the total base-exchange capacities of the soils. Potassium and sodium represented approximately 15 percent of the total base-exchange capacity at the end of 5 yr. of treatment, and this resulted in some deflocculation of soil colloids. There was some increase in exchangeable calcium on the soil of least base-exchange capacity, but a decrease in this constituent in the other three cases. "Less calcium was leached than could be calculated from the amounts added in the fertilizer and in the change of exchangeable calcium, indicating some retention of this element in nonexchangeable form, probably as tricalcium phosphate." Magnesium was leached in amounts approximating to the fertilizer application. There was no consistent change in total base-exchange capacity and only a slight increase in degree of base saturation.

The ammonium sulfate treatment "greatly depleted all of the exchangeable bases—calcium, magnesium, potassium, and sodium—but to a smaller degree than could be calculated from the difference between bases added and the leaching of nitrates and sulfates. Large losses of aluminum and manganese in the drainage water accounted for part of this discrepancy. However, losses of calcium by leaching were in excess of the sum of the amounts added and the losses of the exchangeable form, indicating a liberation of nonexchangeable calcium. Exchangeable potassium was severely depleted . . . despite a liberal application of this element in the fertilizer." The quantities of potassium in the leachates were significantly higher than for the other treatments.

"Ammonium sulfate depleted exchangeable magnesium to a smaller percentage of the original amounts in the soil than in the case of the other bases. . . . This treatment reduced all four soils to similar degrees of base saturation, although the soils varied widely with respect to initial base satura-

tion and total base-exchange capacity. . . . There was a small but consistent increase in base-exchange capacity. . . .

"Urea was materially less severe than ammonium sulfate in its effect upon soil bases. It consistently depleted exchangeable calcium, magnesium, and sodium, but permitted an increase in exchangeable potassium on two of the four soils. Its net effect in depletion of exchangeable bases was of the same order of magnitude as the calculated effect resulting from its nitrification."

Cottonseed meal produced losses in exchangeable bases similar to those caused by urea.

"Nitrogen recovery in combined crop and leachings from the cropped tanks approximated to the drainage water losses on the uncropped surface soil of the same type. Total removal of bases from the soil (exclusive of aluminum and manganese, which did not appear in the leachates from the deeper tanks) were not significantly different in the two cases. Data as to pH and exchangeable hydrogen on samples taken at the end of 5 yr. indicate slightly greater alkaline effects from the sodium nitrate treatment on the cropped soil."

The use of rapid soil tests in the United States, R. P. THOMAS (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 411–419, figs. 2*).—The conclusions quoted were derived from the answers to a questionnaire sent to all the States.

"The use of rapid tests for determining soil deficiencies is extensive. The Middle Western, East-Central, Central Atlantic, and Northeastern States seem to be the most active in this work. The tests for pH value were used more than any other single determination. Lime requirement determinations were made in many States even though pH determinations were made.

"The estimation for phosphorus deficiency was made in two-thirds of the States. Many of these States used more than one method, which indicated that at the present time no one method is entirely satisfactory. The rapid determination for potassium was much more limited. The Corn Belt States, East-Central, Central Atlantic, and Northeastern States were the centers for these tests. Very few States made separate tests for calcium and magnesium unless it was included in the method used in making other determinations. Organic matter, nitrate nitrogen, alkali, and plant tests were reported as being made occasionally by some States. The Eastern Corn Belt States made the largest number of rapid soil tests, with the Central Atlantic States a close second.

"It is very difficult to determine the cost since the methods of reporting varied considerably. The responsibility of the rapid soil testing fell for the most part on the experiment station and teaching staffs. County agents and agricultural teachers made a large portion of the tests in some States, although many States indicated that this was not very desirable. For the most part this service was financed by the experiment station or college, although in some cases the extension service bore all of the expense, while in others it was cooperative.

"Practically every department which does any soils work reported some work with rapid tests. Due to the unsatisfactory results of the tests often reported by the different workers, the majority believe that centralization of the testing in one or two places in each State would be better. Commercial companies on the whole are not encouraged to offer this service to the farmer. Most States reported the results of their tests in letters or symbols. It seemed to be more desirable to send the interpretations and recommendations based upon all obtainable information rather than the results of the tests alone.

"The results indicated that there needs to be considerable collaboration on the treatment of the soil samples and interpretations of the tests made before a comparison of methods can be made. At the present time the most of the States indicated that the rapid tests have been checked under field conditions only to a limited extent. The demand for the use of these tests is increasing rapidly. Since these tests are based on fundamental research and are limited in themselves, very few workers felt that a state of perfection in rapid soil testing had been reached."

Behavior of replaceable cations in the soil and their availability, J. S. JOFFE (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 66, 67*).—The author of a note contributed from the New Jersey Experiment Stations comments briefly upon the results of experiments on the growth of plants in soils of which the exchange complex had been saturated with the calcium, magnesium, potassium, ammonium, and hydrogen ions. The hydrogen saturated soil was prepared by treatment of the soil with a solution of phosphoric acid, and this soil served, therefore, as a source of phosphorus. Soluble salts were removed by dialysis.

"The data obtained corroborate the general observations that the single cation soil is capable of producing a crop which indicates that plants may use the potential cation and anion resources of the soil outside of those in the exchange complex. The NH_4 soil alone appears to be unfit for plant growth, probably due either to the toxicity of the preponderating NH_4 ion or to the increased OH-ion concentration as suggested by Gedroiz. The original untreated soil is sufficiently well supplied with N, which under favorable conditions becomes available. There is, however, clear-cut evidence of the availability of the N from the NH_4 soil. It is an admirable source of N for plants. Calcium from the complex is readily available, frequently more so than the Ca from $CaCO_3$. The NH_4 and especially K ions in the complex seem to depress the intake of Ca from the H soil, which by itself seems to mobilize Ca. Additions of Ca soil to the K soil increased the yield on the latter. The H soil alone is capable of producing a crop, and the results are explained on the basis of the increased acidoid-basoid ratio due to the PO_4 ions. The total exchange capacity of this soil also increased. The variations in the P content of the plants on the H soil and the inhibitory effects of Ca on the P intake are brought out."

Absorption of potassium by plants and fixation by the soil in relation to certain methods for estimating available nutrients, D. R. HOAGLAND and J. C. MARTIN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 99–103, fig. 1*).—Basing their conclusions upon some 7 or 8 years' study of a considerable number of California soils, carried out at the University of California, the authors "find no reason to believe that any chemical or biological method of a laboratory type will ever be developed by which it will become possible to predict for widely diverse soil, crop, and climatic conditions, with even approximately uniform success, the response of a crop to the application of potassium fertilizers under field conditions. The function of such methods is to be found rather in special investigations of general soil and plant interrelations under highly controlled conditions, and in preliminary field surveys made for the purpose of selecting areas for the establishment of field experiments, possibly eliminating for the time certain areas in which laboratory studies indicate the soil to have an exceptionally high power to supply potassium. The final practical answer in any given case must conform to the results of carefully planned and long continued experiments under field conditions."

Factors affecting the retention of phosphate by clays, R. BRADFIELD, G. SCARSETH, and J. G. STEELE (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935,*

Trans., vol. 1, pp. 74, 75).—This note is a joint contribution from the Ohio State University, the Soil Erosion Service, State College, Pa., and the Alabama Experiment Station.

Phosphate retention was found to be due to at least three distinct mechanisms which overlap under natural conditions but may be separated under suitable experimental conditions.

"At pH values from 2.0–5.0 the retention is due chiefly to the gradual dissolution of Fe and Al and their reprecipitation as phosphates. At pH 4.5–7.5 the phosphate seems to be fixed on the surface of the clay particles. This reaction proceeds very quickly and shows a fairly sharply defined saturation value which is independent of the concentration of the PO_4 added. This saturation value seems to bear no direct relationship to the base-exchange capacity. It is with the clays studied only 20–45 percent of the base-absorbing capacity. At pH 6.0–10.0, if divalent cations are present the phosphate will be fixed largely by the divalent cations."

A simple method of finding the lime status and lime requirement of soils, based on reaction with $CaCO_3$, A. N. PURI and A. S. VANSHYLLA (*Soil Sci., 41 (1936), No. 5, pp. 361–365*).—The authors outline a method of determining the lime status and lime requirement of soils, the procedure to consist essentially in the estimation of exchangeable calcium before and after treatment with $CaCO_3$ by the potassium oxalate method.

It was found that, within limits, the results obtained are independent of the amount of soil, the strength of solution, or the time of shaking. Illustrative results obtained in experiments with some typical Indian soils are shown.

Nitrogen fixation in soybeans as influenced by exchangeable calcium, W. A. ALBRECHT and G. M. HORNER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 140–144, figs. 2*).—Data here reported from the Missouri Experiment Station indicate that "as the soil offered a constant amount of exchangeable calcium, but at different degrees of calcium saturation, the plant growth, the extent of nodule production, and the nitrogen fixation increased with the percentage of calcium saturation. . . .

"For the particular soil colloid used in this study, a constant level of exchangeable calcium at 87.5 percent saturation for this nutrient element was approximately twice as effective in nodule production and nitrogen fixation as it was at 40 percent saturation. The total amount of calcium taken by the crop was also almost doubled. The percentage content of the crop of this nutrient element was increased about one and one-half times by the higher percentage calcium saturation, paralleling the greater calcium exchange that takes place with increasing calcium saturation when the colloid is in equilibrium with a salt solution."

Conditions which favour nitrogen fixation by a blue-green alga, F. E. ALLISON and S. R. HOOVER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 145–147*).—From the results of an investigation carried out at the U. S. D. A. Bureau of Chemistry and Soils, the authors conclude that "blue-green algae are of considerable importance in adding to the earth's supply of fixed nitrogen. Judging by the data obtained with the one species of *Nostoc*, it would seem that these organisms thrive best in neutral soils, preferably partly shaded, and where moisture is abundant. Since *Nostoc* can fix nitrogen in the dark if given a satisfactory energy supply, it is probable that nitrogen fixation would be favored by the presence of an abundance of decaying organic matter, especially if the carbon-nitrogen ratio of the latter is wide. The organism is commonly found growing abundantly in small pools of fresh water, and certainly it must be an important nitrogen fixer under such conditions."

The production of ammonia by Azotobacter and its relation to the mechanism of nitrogen fixation, D. BURK and C. K. HORNER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 148–151*).—Cultures of *A. vinelandii* and of *A. chroococcum* were grown in the Warburg apparatus after various pretreatments at the U. S. D. A. Bureau of Chemistry and Soils. It was observed, in part, that "*Azotobacter* possesses enzymes which enable it to ammonify very great numbers of nitrogenous compounds under both anaerobic and aerobic conditions. It also fixes a large proportion of its nitrogen in a form readily convertible to NH_3 under proper external conditions, which the soil, by virtue of its heterogeneity, is capable of providing at one time or another. Whether *Azotobacter* might fix and liberate a great deal more NH_3 than corresponds to its cell nitrogen derived from N_2 remains to be demonstrated."

The specific catalytic role of molybdenum and vanadium in nitrogen fixation and amide utilization by Azotobacter, D. BURK and C. K. HORNER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 152–155*).—The authors of this contribution from the U. S. D. A. Bureau of Chemistry and Soils express the belief that, "in the light of the present results, some amide is the only compound which would appear so far to have received fairly strong experimental support in connection with being a specific intermediate in the chemical mechanism of nitrogen fixation by *Azotobacter*. Hydroxylamine . . . can scarcely be an intermediate since . . . *Azotobacter* is unable to utilize hydroxylamine as a source of nitrogen. For the same type of reason, or because of relations with respect to temperature, Mo and V, or Ca and Sr, many common nitrogenous compounds, such as urea, ammonia, nitrite, nitrate, hydrazine, asparagine, glycine, and other organic forms . . . do not appear to behave sufficiently like N_2 in the over-all growth process to indicate that they are specific intermediates in fixation."

The function of cellulose and lignin in the preservation of nitrogen in soils and in composts, S. A. WAKSMAN and I. J. HUTCHINGS (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 163–167*).—In a brief discussion contributed from the New Jersey Experiment Stations, the authors present the view that the preservation of nitrogen in a sand medium depends on a number of factors, among the most important of which are the form in which the nitrogen is added and the nature of the organic substances which serve as sources of humus. "The function of the various constituents of the plant residues in the preservation of the nitrogen differs considerably. Carbohydrates supply the readily available energy for the activities of the microorganisms, with the result that the nitrogen is transformed into microbial cell substance. The function of lignin in the preservation of the nitrogen consists in acting as a buffer for the absorption of the ammonia and in the direct fixation of some of the protein."

The response of rhizobia to natural humic acid, F. E. ALLISON and S. R. HOOVER (*Soil Sci., 41 (1936), No. 5, pp. 333–340, fig. 1*).—Experiments carried out at the U. S. D. A. Bureau of Chemistry and Soils with two species of legume nodule bacteria, *Rhizobium trifolii* and *R. meliloti*, show that the addition of natural humic acid to a synthetic medium (sugar, inorganic salts, and nitrate) produces a marked increase in bacterial numbers and oxygen consumption. The growth obtained, over the concentration range of 0–600 p. p. m. dry matter, was nearly proportional to the quantity added. In the absence of humic acid, and in media in which a very pure sugar was used, no appreciable growth occurred. Synthetic humic acids, prepared by boiling sugar in sulfuric acid, failed to produce a corresponding growth response in these rhizobia regardless of the iron content of such preparations.

"The growth response of the clover and alfalfa nodule bacteria to natural humic acid is due almost wholly to the presence of an essential growth substance and not to the available iron content. This substance, coenzyme R, is essential for respiration and growth of these organisms. The iron requirements of rhizobia are small. The stimulating effect of additions of available iron was usually less than 10 percent in a synthetic medium prepared from C. P. ingredients."

Azotobacter chroococcum and *A. vinelandii* showed no growth response to coenzyme R, which is synthesized by the last-named species to an extent such that *A. vinelandii* was used as one of the sources of the coenzyme.

Chemical changes during decomposition of pineapple trash under field conditions, R. K. TAM and O. C. MAGISTAD (*Soil Sci., 41 (1936), No. 5, pp. 315–327, figs. 2*).—In an experiment begun on November 1, 1934, at the Hawaii Experiment Station, the residual leaf material after a 35-week decomposition period was only 9 percent of the original 18.6 tons per acre dry-leaf portion of the trash. Of the original 8.4 tons of stumps (dry basis), 19 percent remained undecomposed.

All of the organic fractions found in trash underwent decomposition to a certain degree, some proceeding at a greater rate than others. In the order of increasing resistance to decomposition, the various fractions were as follows: Water-soluble fraction, ether-soluble fraction, alcohol-soluble fraction, hemicelluloses, celluloses, and lignins. Water-soluble reducing sugars were decreased from 5.94 to 2.61 percent in the leaf material during the first 2 weeks of decomposition. At the end of 7 weeks only traces of reducing sugar were detectable. This loss was also shown to occur in the case of the stump material. Crude protein in trash increased as decomposition proceeded, whereas water-soluble nitrogen decreased. During the last 12 weeks a decrease in crude protein was detected, with a corresponding increase in water-soluble nitrogen.

The original soil carbon-nitrogen ratio was 4.8:1. With the addition of 27 tons of trash (dry basis), approximately 58 percent of which was carbon, the ratio was increased to 10.8. At the end of 35 weeks of decomposition the carbon-nitrogen ratio was reduced to 5.9, 3.2 tons of residual trash held on a 16-mesh sieve being taken into consideration. The carbon-nitrogen ratio of 16-mesh soil was 5.2. Available nitrogen in soils decreased during the first 23 weeks of decomposition but increased during the last 12 weeks.

Replaceable potassium in the soil continually increased from 0.31 to 1.03 milliequivalents of K_2O in each 100 g of soil, or from 350 to 1,160 lb. per acre-foot, during the 35-week period. This was released from the incorporated trash during decomposition.

Easily soluble phosphorus decreased during the earlier stages of decomposition, regaining its former level in the soil toward the end of the decomposition period.

AGRICULTURAL BOTANY

[Phytophysiological studies by the New Jersey Stations] (*New Jersey Stas. Rpt. 1935, pp. 71–77*).—Brief summaries are given under the following projects: A study of the absorption of "supplementary elements" required in plant metabolism; a report of the analyses for mineral constituents (K, P, Ca, and Mg) of corn plants grown in culture solutions at pH values ranging from 3.0 to 8.0; iron content of corn plants grown in culture solutions at pH levels ranging from 3.0 to 8.0; and the effect of concentration of the nutrient solution on the growth and composition of the tomato.

A study of certain factors influencing the movement of liquids in wood, S. J. BUCKMAN, H. SCHMITZ, and R. A. GORTNER (*Jour. Phys. Chem., 39 (1935),*

No. 1, pp. 103–120, figs. 7; abs. in Minnesota Sta. Rpt. 1935, pp. 26, 27).—In this study at the Minnesota Experiment Station, the maximum and average effective diameters of the pores in the pit membranes of the wood were found to vary with the moisture content. Below the fiber-saturation point, effective pore diameters decreased with increasing moisture. The influence of pressure on the rate of water flow through wood proved to be a characteristic of the kind of wood. The relationship between pressure and rate of water flow is perhaps influenced by such factors as thickness of the pit membrane and presence and effectiveness of resin canals. This relationship in several woods was not significantly changed by drying the wood before use, nor did such drying appear to cause pronounced, permanent changes in the permeability of the woods to water.

The rate of flow of organic liquids or salt solutions could not be predicted necessarily from their viscosities, and the same was true for the rate of flow of organic liquids through Norway pine sapwood. The evidence indicated that the magnitude of the deviations from a viscosity relationship for the flow of organic liquids would differ for different kinds of wood. The decrease in rate with time in balsam fir heartwood for benzene, bromobenzene, and nitrobenzene increased with increasing polarity of the liquid. Apparently the movement of liquids of widely different properties in wood cannot be predicted necessarily from the viscosity alone, other factors entering into the picture (e. g., the influence of the liquid on the effective capillary dimensions of the openings in the wood and the possible effect of electrical "back pressure" on the flow of polar organic liquids). The relative importance of factors other than viscosity may perhaps be expected to vary with the kinds of wood and the properties of the liquids.

Some aspects of the internal water economy of the sugar cane plant, H. A. WADSWORTH (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 40 (1936), No. 1, pp. 21–33, figs. 4*).—"Some evidence is present that the moisture content of H 109 cane, grown under irrigated conditions, suffers a diurnal variation of considerable magnitude. Such moisture content is higher at daybreak and lower at nightfall. Such determinations were made by use of the hand refractometer, it being assumed that variations in Brix might be more accurately charged to variations in moisture than in soluble material. An attempt to duplicate the results with other varieties (P. O. J. 2878 and Yellow Caledonia) at Hilo Variety Station failed to give significant results unless an unconvincing temperature correction is invoked. There is some speculation as to the role of this daily moisture fluctuation and sugar formation."

Effect of ammonium and of nitrate nitrogen on the composition of the tomato plant, H. E. CLARK (*Plant Physiol., 11 (1936), No. 1, pp. 5–24*).—In this study by the Connecticut [New Haven] Experiment Station, tomato plants 1 mo. old were grown subsequently for 49 days in sand cultures with continuously renewed solutions at pH 6.7, in (1) calcium nitrate ($Ca(NO_3)_2$), in (2) an equivalent amount of ammonium sulfate ($(NH_4)_2SO_4$), and in (3) one-third as much $(NH_4)_2SO_4$. Analyses of the harvested, dried tissue indicated the effects of the form and concentration of nitrogen of the solutions on the growth and composition.

Differences between the "nitrate" and the "ammonium" plants were diminished by decreasing the $(NH_4)_2SO_4$ concentration. The fresh weight of the tops was greater in the nitrate than in the ammonium series, but there was no significant difference in weight with respect to plants in dilute v. concentrated $(NH_4)_2SO_4$ solutions. The dry matter was slightly higher in the ammonium stems, but that in the leaves of all series was about the same. A

high concentration of nitrate nitrogen occurred in the nitrate plants, and consequently the total unassimilated nitrogen was much higher there. A considerably greater amount of ammonium nitrogen occurred in the ammonium series, and more in those in the concentrated than in the dilute solutions. Much greater amounts of glutamine and of asparagine nitrogen were found in the ammonium series, indicating the ready formation of amide from ammonium nitrogen. More total amino nitrogen occurred in the ammonium series, but this was due largely to the higher concentration of glutamine and asparagine. Amino nitrogen (exclusive of glutamine and asparagine) formed a small part of the total amino nitrogen in the ammonium plants, but a relatively large part in the nitrate group. A higher concentration of soluble organic nitrogen was present in the ammonium plants, and the larger part of this occurred in forms analytically established, while in the nitrate plants the larger part of the total soluble nitrogen was in undetermined forms. The concentration of insoluble ("protein") nitrogen was higher in the ammonium series, but the percentage of ash was greater in the nitrate plants. The concentration of the three known acids (oxalic, malic, and citric) was much higher in the nitrate plants and the amount of total organic acids was also greater, but of the latter the known acids constituted the greater portion in the tops. On the other hand, the unknown acids composed the larger part of the total acids in the ammonium series and in the roots of the nitrate plants.

"An interrelationship is suggested between the absorption and assimilation of nitrogen, the accumulation of ash constituents, and the synthesis of organic acids by the plants, evidence of the complexity of the effect of the form of nitrogen in the culture solution."

Zinc sulphate studies in the soil, O. E. GALL (*Citrus Indus., 17 (1936), No. 1, pp. 20, 21*).—In this study by the Florida Experiment Station, greenhouse and pot tests were carried out to determine what became of the zinc after it was added to the soil and how much could be added before reaching the toxic limits. The results appear to indicate but little danger of zinc toxicity developing in soils from the present recommended applications of zinc sulfate.

The effect of certain chemicals on the catalase activity in plants, R. H. LANDON (*Amer. Jour. Bot., 21 (1934), No. 9, pp. 583–591, fig. 1; abs. in Minnesota Sta. Rpt. 1935, p. 13*).—In this contribution from the Minnesota Experiment Station an accurate and rapid method for catalase determinations is described.

The toxicity of a chemical could not be determined accurately from its effect on the catalase activity of tissue preparations, nor could it be predicted from its similarity to compounds of known toxicity.

The measurement of changes in catalase activity should prove useful in studying the herbicidal properties of chemicals, provided the toxic action peculiar to the chemical being investigated is taken into consideration.

Effect of petroleum oils on the respiration of bean plants, apple twigs and leaves, and barley seedlings, J. R. GREEN (*Plant Physiol., 11 (1936), No. 1, pp. 101–113, figs. 2*).—In this study by the Montana Experiment Station, the averages of several tests with plants sprayed with poorly refined oils indicated an increased respiratory rate, though individual determinations showed that in some cases it was retarded. The averages of similar tests with highly refined oils also gave an increase, but to a smaller extent, and individual determinations indicated that these oils also may retard respiration. The changes in rate thus induced extended over long periods. When large amounts of oil were sprayed on barley seedlings, about the same respiratory change was induced as with small amounts.

Transpiration and the cooling of leaves, O. F. CURTIS (*Amer. Jour. Bot., 23 (1936), No. 1, pp. 7–10, fig. 1*).—In this contribution by Cornell University, it

is stated that "since leaves enclosed in cellophane envelopes or glass chambers and exposed to strong light reach temperatures about 20° C. higher than similar leaves covered with vaseline, and since vaseline may not completely prevent transpiration, some investigators have concluded that transpiration has a more pronounced cooling effect than commonly thought and that high temperatures of leaves in envelopes transparent to visible radiation are due chiefly to stoppage of transpiration. Cellophane envelopes, however, have similar effects in raising the temperature of dry, black paper. The excess temperature is chiefly due to the trapping effect of the envelope, which reduces heat loss by conduction and radiation.

"It is suggested that the higher leaf temperatures relative to air temperatures in humid regions, which are usually ascribed to diminished transpiration, are partly due to the effect of the high moisture of the atmosphere in preventing loss by radiation in the infrared."

Further studies on exudation in cucurbits, A. S. CRAFTS (*Plant Physiol., 11 (1936), No. 1, pp. 63–79*).—Continuing this study[1] by the California Experiment Station, phloem exudate was collected from squash plants for periods of 12 and 24 hr. The exudation fluctuated in rate but did not stop. That from excised stems depended in volume on the size of the stems and not on the condition of local tissues. Excised root systems of squash exuded more than their own weight in xylem sap in 24 hr. Phloem exudate was about 8 to 20 times as concentrated as xylem exudate.

Phloem sap from cucurbits coagulated with heat, alcohol, or long standing. Xylem sap did not coagulate. Phloem sap exuded in relatively small quantities, soon stopping, and exudation could be maintained only by frequent cutting. Xylem sap exuded in much larger quantities and flowed for hours without interruption. Phloem exudation may take place from wilted plants. Xylem exudation occurs only where transpiration loss has been greatly reduced or eliminated. Phloem sap had a pH of 7.3 and was well buffered. Xylem sap was practically unbuffered and had a pH of 5.5. Plugging of the phloem apparently results from the coagulation of the phloem sap within the interstices of the walls of the cut phloem elements.—(*Courtesy Biol. Abs.*)

The effect of centrifugal force on root-tips of Pisum sativum at various temperatures, H. T. NORTHEN (*Amer. Jour. Bot., 23 (1936), No. 1, pp. 64–69, figs. 8*).—In this contribution by the State College of Washington, comparisons were made of the effects of a centrifugal force 1,000 times that of gravity for a maximum of 15 min. on the root tips of pea plants previously maintained at constant temperatures of 10°, 25°, and 35° C., respectively. The ease of throwing down the nucleus and cytoplasm was correlated with the cell sap specific gravity. In the plerome cells of the meristematic region the sap specific gravity was equal to that of the cytoplasm and nucleus, but in older plerome cells and in most cells of the periblem the sap specific gravity was lower. By noting the degree of movement of the nucleus through the cytoplasm, it is concluded that in the meristematic region of the plerome and in the periblem cells the specific gravity of the nucleus and cytoplasm is the same, but that in the older plerome cells that of the nucleus is greater.

The chondriosomes did not move in centrifuging, and hence are concluded to have a specific gravity about equal to that of the cytoplasm. The nucleoli, nuclear reticula, and prophase chromosomes were in no case displaced, indicating their specific gravity to equal that of the nuclear sap.

The viscosity of the cytoplasm during mitosis cannot be determined by noting the displacement of the mitotic figure, the degree of displacement apparently

[1] Plant Physiol., 7 (1932), No. 2, pp. 183–225, pls. 6, fig. 1.

being determined more by the relative densities of the cell sap, cytoplasm, and mitotic figure than by the viscosity of the cytoplasm. The centrifuged mitotic figures behaved like the nuclei in adjacent cells, suggesting their specific gravity to be the same as that of the nucleus.

Growth of fragments of excised root tips, W. J. ROBBINS, M. BARTLEY, and V. B. WHITE (*Bot. Gaz., 97 (1936), No. 3, pp. 554–579, figs. 16*).—In this study by the University of Missouri, excised corn root tips cultured under sterile conditions in a nutrient medium grew in most cases when 0.5 mm or more long, and in all cases when 0.9 mm or more long. Divided longitudinally into equal parts, each part of the excised root tips of corn and pea from 1 to 2 mm long developed into complete roots in the medium used. When such root tips were similarly divided so that one part contained most of the plerome, the larger part developed into a complete root, while the smaller part grew but lacked one or more portions. When similarly divided into three or more pieces, a piece comprising less than one-half of the root tip developed into a complete root, but one containing only a quarter did not. Divided obliquely through the apex of the meristem, both pieces sometimes, but not always, developed into a complete root. Similarly divided through the basal part of the meristem, the tip piece developed into a complete root, but the basal part formed no apical meristem. When wheat root tips were divided longitudinally, neither piece developed into a complete root. The same was true when the tips were cut obliquely or transversely through the meristem apex, but when similarly cut through the basal part of the apical meristem the tip fragments developed into complete roots and the basal fragments regenerated a new apical meristem.

There were four types of response in fragments of apical meristems of root tips, viz, little or no development, formation of filaments of parenchyma cells, formation of a root in which stelar tissue differentiated but no apical meristem remained, and formation of a normal root. Injury by the cut may affect the character of the development of fragments of the apical meristem of roots.

The effect of electrolytes present in the growth media upon the electrophoretic mobility of Escherichia coli, J. T. PEDLOW and M. W. LISSE (*Jour. Bact., 31 (1936), No. 3, pp. 235–244, figs. 2*).—This is a contribution by the Pennsylvania Experiment Station.

The effect of certain X-rays on the electrophoretic mobility of Escherichia coli, M. E. SMITH, M. W. LISSE, and W. P. DAVEY (*Jour. Bact., 31 (1936), No. 3, pp. 275–286*).—This is a contribution by the Pennsylvania Experiment Station.

North American species of Monilinia.—I, Occurence, grouping, and life histories, E. E. HONEY (*Amer. Jour. Bot., 23 (1936), No. 2, pp. 100–106, figs. 4*).—This paper from the University of Wisconsin introduces a series of studies initiated to increase the knowledge of the North American Monilinias. The generic concepts of *Oidoria*, *Sclerotinia*, *Ruitstroemia*, and *Stromatinia* are briefly mentioned, and the methods of study, both in the field and laboratory, are indicated.

The species included under *Monilinia* are divided into two sections on the basis of the presence or absence of disjunctors within the macroconidial fruiting chains, and the disjunctor and the method of separation of the macroconidia are described and illustrated. Aromatic odor, life histories, and specialization of parasitism are correlated with the morphologic grouping into the two sections. Representative species of the two sections are listed, with notes.

Hydrogen-ion concentration and the toxicity of basic and acid dyes to fungi, E. KOBS and W. J. ROBBINS (*Amer. Jour. Bot., 23 (1936), No. 2, pp.*

133–139, figs. 6).—In this study by the University of Missouri a uniform concentration of eosin, rose bengal, or dahlia dyes was added to cultures of *Gibberella saubinetii*, *Fusarium oxysporum*, and *Rhizopus nigricans* at pH values of from 4.0 to 8.0. The toxicity of each dye was then determined by comparing the growth on the medium at a particular pH value with and without the dye.

A concentration of rose bengal, with little effect on the *G. saubinetii* growth at pH 7.3, completely inhibited it on potato dextrose agar at pH 4.5. In some cases even the change of a fraction of a pH had a marked effect. In general, an increase in acidity increased the toxicity of the acid dyes eosin and rose bengal and decreased that of the basic dahlia, but the precipitation of the rose bengal in the most acid solutions in some cases reduced its toxicity.

Changes in reaction due to the growth of the organisms may obscure the true correlations, and to overcome this difficulty bits of mycelium were placed in sodium phosphate buffer mixtures at from pH 3.8 to 8.2 with and without the dye. After 12 hr. the mycelia were removed and cultured on potato dextrose agar. The acid dye rose bengal was most injurious in the more acid solutions, while the basic dye dahlia was most so in the more alkaline solutions.

It is believed that the effect of pH on the dye toxicities is due to its influence on the formation by the dyes of free base or acid. Correlations between the isoelectric points and the effects of pH on the toxicities of the dyes were not evident in these experiments.

Dissociation of Saccharomyces aceris-sacchari Fabian and Hall and Pichia alcoholophila Klöcker, L. J. WICKERHAM and F. W. FABIAN (*Jour. Infect. Diseases, 58 (1936), No. 2, pp. 165–171, figs. 19*).—This is a contribution by the Michigan State College.

The status of the generic term Bacterium Ehrenberg, 1828, R. S. BREED and H. J. CONN (*Jour. Bact., 31 (1936), No. 5, pp. 517, 518*).—In this contribution from the New York State Experiment Station, the authors recommend "that *Bacterium* be accepted as a temporary generic term with an admittedly unrecognizable type species *B. triloculare* Ehrenberg to include those species of non-spore-forming, rod-shaped, motile, or nonmotile bacteria whose relationships to other bacteria are not clear. When relationships to other similar species have been developed by investigation, then this generic term would naturally be dropped. This would permit, for example, the retention of such a species as *B. radiobacter* in the genus *Bacterium* until its systematic position is better understood."

A study of the species Lactobacillus plantarum (Orla-Jensen) Bergey et al., C. S. PEDERSON (*Jour. Bact., 31 (1936), No. 3, pp. 217–224, figs. 2*).—This contribution by the New York State Experiment Station retains the name *L. plantarum* for the species here characterized.

Diversion of the normal heterolactic dissimilation by addition of hydrogen acceptors, M. E. NELSON and C. H. WERKMAN (*Jour. Bact., 31 (1936), No. 6, pp. 603–610*).—This contribution by Iowa State College shows that acetaldehyde and acetylmethylcarbinol added to fermentations of glucose by *Lactobacillus lycopersici* are readily hydrogenated.

The aerobic dissimilation of lactic acid by the propionic acid bacteria, C. ERB, H. G. WOOD, and C. H. WERKMAN (*Jour. Bact., 31 (1936), No. 6, pp. 595–602*).—This is a contribution by Iowa State College.

Studies on anaerobic bacteria.—IX, Antigenic relations of Clostridium bifermentans and Clostridium centrosporogenes, E. McCOY and L. S. MCCLUNG (*Jour. Bact., 31 (1936), No. 5, pp. 557–568*).—Continuing this series

(E. S. R., 74, p. 179), the serological evidence presented in this study from the University of Wisconsin, together with morphological and physiological data, leads to the conclusion that the concept of a single species, *C. bifermentans*, is adequate.

The nitrogen distribution of Azotobacter chroococcum, J. E. GREAVES and W. REEDER (*Utah Acad. Sci., Arts, and Letters, Proc., 12 (1934–35), pp. 97–100*).—In this study by the Utah Experiment Station, *A. chroococcum* secreted no soluble nitrogen in the synthetic medium used. As determined by the micro-Van Slyke method, its protein is similar to that of the leaves of spinach and alfalfa and thus probably plantlike in nature. Since all plant (and other) proteins must be broken down before they are utilized by other plants, it is believed that the proteins of *A. chroococcum* must also be decomposed by other micro-organisms before the higher plants can utilize the fixed nitrogen.

Preparation of sintered Pyrex glass aerators for use in water culture experiments with plants, A. H. FURNSTAL and B. JOHNSON (*Plant Physiol., 11 (1936), No. 1, pp. 189–194, figs. 4*).—In this contribution by the University of California, details of technic are presented for the grinding, grading, and sintering of glass particles into inert, resistant aeration units of uniform quality and capable of dispersing gases in fine bubbles. Construction diagrams are included.

A dilatometer for plant materials, G. A. GREATHOUSE and M. W. PARKER (*Plant Physiol., 11 (1936), No. 1, pp. 209–211, fig. 1*).—The dilatometer described in this contribution by the University of Maryland is an all Pyrex glass system which can be evacuated and filled without disturbing the material used as a sample.—(*Courtesy Biol. Abs.*)

Plant material introduced by the Division of Plant Exploration and Introduction, Bureau of Plant Industry, January 1 to March 31, 1934 (*U. S. Dept. Agr., Inventory 118 (1936), pp. 41*).—This number lists 1,047 lots of plant material. Many descriptive notes are included.

GENETICS

Chromosome numbers in the Leguminosae, D. C. COOPER (*Amer. Jour. Bot., 23 (1936), No. 3, pp. 231–233, figs. 16*).—Chromosome numbers are reported from studies at the Wisconsin Experiment Station probably for the first time in 13 species representing 7 genera of the Leguminosae. The somatic numbers reported are: *Lespedeza variegata* $2n=18$, *L. sericea* 18, *L. stipulacea* 20, *L. tomentosa* 20, *L. daurica* 36, *Medicago dzawakhetica* 16, *M. heniocyela* 32, and *M. glutinosa* $2n=32$. The haploid numbers reported are: *Baptisia australis* $n=9$, *Lupinus polyphyllus* 24, *Desmodium grandiflorum* 11, *Swansonia galegifolia* 16, and *Amphicarpa monoica* $n=10$. Two satellite chromosomes were observed in the somatic divisions of *L. variegata*, *L. tomentosa*, and of the three species of *Medicago*. The somatic chromosomes of the *Lespedeza* species range from 1.5μ to 5μ in length, whereas those of the *Medicago* species range from 2μ to 3.5μ in length.

Inheritance of resistance to Ustilago levis (K & S) Magn. (covered smut) in a cross between Markton and Colorado 37 oats, W. W. AUSTIN and D. W. ROBERTSON (*Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 467–471*).—Behavior in the F_3 of Colorado 37 (susceptible) × Markton (resistant) oats at the Colorado Experiment Station indicated that a two-factor difference for smut exists between the parents. Markton possesses the two dominant factors for resistance, while Colorado 37 has the recessive allelomorphs of these factors. Some promising, highly resistant lines were being continued

in the hope of developing some high-yielding, smut-resistant, commercial strains.

Inheritance of seedling stem color in a broomcorn-sorghum cross, C. M. WOODWORTH (*Jour. Amer. Soc. Agron., 28 (1936), No. 4, pp. 325–327*).—The breeding behavior in F_3 of red-stemmed F_2 plants of Shallu × Black Spanish broomcorn, in Illinois Experiment Station studies, approximated the ratio of one plant breeding true for red; four segregating for red and green in a 3:1 ratio; and four segregating for red and green in a 9:7 ratio, confirming expectations based on two genes, both of which must be present to produce red.

Squash-pumpkin hybrids throw light on evolution of these forms, G. P. VAN ESELTINE (*Farm Res. [New York State Sta.], 2 (1936), No. 4, pp. 6, 9, fig. 1*).—Interspecific crosses between the three species of cucurbits, namely, *Cucurbita maxima*, *C. moschata*, and *C. pepo*, resulted in some fertile hybrids in the case of *C. moschata* × *C. pepo*. *C. maxima* ×. *C. moschata* yielded hybrids the staminate flowers of which were sterile, forming no pollen. Self-pollination of the fertile *moschata* × *pepo* hybrids yielded fruits with viable seeds, plants from which when studied as to the inheritance of various stem, fruit, leaf, and flower characters gave evidence that *C. moschata* is probably the most ancient form, from which came first *C. maxima* and lastly *C. pepo*. Among the new types were some that apparently were either immune or highly resistant to squash mosaic, and efforts to develop attractive and productive varieties are in progress. A detailed analysis is presented of the breeding results.

Cytology and fruit breeding.—IV, How hybrid ratios are predicted, B. R. NEBEL (*Farm Res. [New York State Sta.], 2 (1936), No. 4, p. 11, figs. 2*).—In this fourth contribution (E. S. R., 75, p. 191) the author discusses with diagrams the backcrossing of a peach × nectarine F_1 hybrid with its nectarine parent, with special reference to the segregation of the fuzz character in the resulting progeny.

Physiological and evolutionary theories of dominance, S. WRIGHT (*Amer. Nat., 68 (1934), No. 714, pp. 24–53, figs. 7*).—In presenting statistical evidence on theories relating to physiological explanations of dominance, it is pointed out that generally the most active phase of a gene is dominant over the less active phases. At the same time dominance may depend upon building up a factor of safety for the most adaptive type of the species.

Professor Wright on the theory of dominance, R. A. FISHER (*Amer. Nat., 68 (1934), No. 717, pp. 370–374*).—A discussion of differences with Wright on the theory of dominance.

Professor Fisher on the theory of dominance, S. WRIGHT (*Amer. Nat., 68 (1934), No. 719 pp. 562–565*).—A further discussion of the theory of dominance.

A dairy sire progeny test, B. L. WARWICK and O. C. COPELAND (*Jour. Heredity, 25 (1934). No. 5, pp. 177–181*).—A dairy sire progeny test is suggested by the Texas Experiment Station based on the use of dams homozygous for multiple recessive factors which are low producers.

A herd of cattle bred for twenty years without new blood, J. L. LUSH (*Jour. Heredity, 25 (1934), No. 6, pp. 209–216, figs. 3*).—A description is given of a purebred Shorthorn herd in which no outside blood was introduced in 20 yr. in an attempt to conserve the good qualities of an outstanding sire. The average relationship of the young herd to the original sire was 42 percent. The average inbreeding was only 16.9 percent. This furnished a demonstration that a moderate-sized herd may follow a close breeding practice with one, later two, and then later one sire with an increase in the uniformity and merit of the resulting herd.

[Sheep breeding] (*South Dakota Sta. Rpt. 1935, pp. 16, 17*).—Results are briefly presented on breeding for taillessness in sheep and quality of fleece of lambs produced by coarse- and fine-fleeced Karakuls.

A faceless lamb, L. M. WINTERS and H. C. H. KEENKAMP (*Jour. Heredity, 26 (1935), No. 1, pp. 33, 34, figs. 2; abs. in Minnesota Sta. Rpt. 1935, p. 22*).—The birth of a lamb in the Minnesota Experiment Station flock which was normal except for the lack of a face is noted. The possible hereditary basis for the condition is discussed.

An eight generation experiment in inbreeding swine, R. E. HODGSON (*Jour. Heredity, 26 (1935), No. 5, pp. 209–217, figs. 2; abs. in Minnesota Sta. Rpt. 1935, pp. 22, 23*).—An account is given of progress made in inbreeding Poland-China swine by brother-sister matings at the Minnesota Experiment Station. Of seven inbred lines started, three were lost in the first generation and one in the third generation due to the reluctance of boars to mate with their litter mate sisters. The other lines were carried to the fifth, sixth, and eighth generations of inbreeding.

It seems evident that disposition is inherited, but the anomalies occurring were considered small.

There was less difficulty in getting boars to mate with their litter mate sisters after the fifth generation. In one line the sows were vicious at parturition, and another line was so docile that they did not take good care of the pigs.

Yellow spotting and white spotting were the principal color anomalies occurring. A few abnormalities in the functioning of the reproductive organs occurred.

It appears that the two main inbred lines with the two subdivisions of each can be continued indefinitely. There was evidence from the litter size, mortality, and rate of growth that inbreds were less vigorous than non-inbreds but the differences were small. Crosses of the inbred lines reached the weight of 200 lb. 4 weeks earlier than non-inbreds and 7 weeks earlier than inbreds.

It appears that segregation of vigor occurred, and some lack of vigor was eliminated through inbreeding.

New pathological hereditary factors in dogs [trans. title], W. KOCH (*Ztschr. Induktive Abstam. u. Vererbungslehre, 70 (1935), No. 3–4, pp. 503–506, figs. 3*).—Several abnormalities which are hereditary in dogs are described.

Polydactylous guinea pigs, S. WRIGHT (*Jour. Heredity, 25 (1934), No. 9, pp. 359–362, figs. 2*).—Attention is called to different types of polydactylous guinea pigs. In one there is an atavistic return of the little toe, the occurrence of which depends upon crossing a physiological threshold and not on segregation of a unit factor. In the other, the heterozygous mutant type usually have thumbs and little fingers whereas the homozygotes show various abnormalities in the legs, face, and belly.

Chinchilla mutation in the wild hare, R. PRAWOCHENSKI (*Jour. Heredity, 26 (1935), No. 4, pp. 145, 146, fig. 1*).—A chinchilla hare shot near the Jagellonian University is described as a parallel mutation occurring in two closely related species.

The production and inheritance of eye defects in rabbits, H. L. IBSEN and L. D. BUSHNELL (*Amer. Nat., 68 (1934), No. 714, pp. 92–95*).—A comparison of the senior author's results (E. S. R., 69, p. 193) and those of Guyer (E. S. R., 44, p. 566) in inducing eye defects in rabbits is presented, from which the authors conclude that proof of the permeability of the placenta to lens antibodies is lacking.

Blood group inheritance in rabbits, C. E. KEELER and W. E. CASTLE (*Jour. Heredity, 25 (1934), No. 11, pp. 433–439, pl. 1, figs. 8*).—The four blood groups in

the rabbit, involving the absence of the agglutinogens or the presence of one or the other or both of the agglutinogens, H_1 and H_2, are described. In the absence of the corresponding agglutinins no agglutination takes place, but the injection of one agglutinogen induces the production of the agglutinins to unite with them. The agglutinogens are transmitted as allelomorphic characters, both dominant to their absence, but neither interferes with the action of the other.

Some protective medium seems to be operating to prevent unfavorable actions that must be expected in certain types of matings where incompatible agglutinins are artificially built up in the dam.

Hereditary brachydactylia and associated abnormalities in the rabbit, H. S. N. GREENE (*Science, 81 (1935), No. 2104, pp. 405–407*).—The occurrence of a deformity in rabbits ranging from brachydactylia to acheiropodia is described. The condition was evidently due to the operation of a single recessive factor. Matings of heterozygotes produced 145 normals and 48 abnormals. Backcross matings produced 31 normal and 19 abnormal young. The abnormals were not as vigorous as normals, and only about 30 percent of the matings of abnormal females resulted in pregnancy. Only two affected males were reared, and no progeny were obtained from them. Attention is called to the similarity of the condition to hereditary abnormalities of the hands and feet in man.

Dominance in the domestic mouse [trans. title], A. L. HAGEDOORN (*Ztschr. Induktive Abstam. u. Vererbungslehre, 70 (1935), No. 3–4, pp. 509–512*).—A discussion of the expression of different characters leads to the conclusion that dominance is only a relative conception.

Linkage of the genes for non-yellow (y) and pink-eye (p_2) in the house mouse (Mus musculus), E. ROBERTS and J. H. QUISENBERRY (*Amer. Nat., 69 (1935), No. 721, pp. 181–183*).—The combined effect of the pink-eye gene (p_2), in the house mouse, and pink eye (p_1) was found to produce a very light-colored coat.

In studies at the Illinois Experiment Station p_2 was found to be linked with nonyellow (y). Among 455 back-cross progeny there were 20 percent cross-overs. Although the differences were small, crossing-over in males was less than in females.

A second rexoid coat character in the house mouse, C. E. KEELER (*Jour. Heredity, 26 (1935), No. 5, pp. 189–191, figs. 2*).—A mutation involving a wavy condition of the coat and short vibrissae was found to be inherited as a simple recessive to the normal. When crossed with the wavy stock of Crew (E. S. R., 69, p. 510) only normals were produced, suggesting that two pairs of genes were involved.

Brown and silver deer mice, R. R. HUESTIS and E. BARTO (*Jour. Heredity, 25 (1934), No. 6, pp. 219–224, figs. 2*).—Coat colors in *Peromyscus maniculatus* corresponding to brown and silver agouti in *Mus* were found due to non-allelomorphic recessive genes.

Two related hairless mutations in the Norway rat, H. W. FELDMAN (*Jour. Heredity, 26 (1935), No. 4, p. 162*).—The two types of hairlessness in the rat described by Roberts (E. S. R., 58, p. 320) and Wilder et al. (E. S. R., 60, p. 194) were found, after crossing the two strains, to be due to identical or very similar allelomorphs, although phenotypical differences in the location and arrangement of the skin folds in aged animals from the two strains were distinguishable.

Reproductive ability and viability of progeny in relation to age of sires and dams, M. A. JULL (*Poultry Sci., 14 (1935), No. 2, pp. 105–111*).—Study of the reproductive ability and viability of the 1925–1931 progeny in relation to the age of sires and dams, among the White Leghorn and Rhode Island Red

birds produced in the flocks of the U. S. D. A. Bureau of Animal Industry, showed that if the progeny of a sire or dam at one age gave good results, good results were also obtained at other ages.

Progeny of inbred and non-inbred Rhode Island Red males, F. A. HAYS (*Poultry Sci., 14 (1935), No. 2, pp. 122–125*).—An analysis at the Massachusetts Experiment Station of the variability and production records of the progeny of 36 non-inbred and 11 inbred Rhode Island Red males showed that the progeny of the inbred males were only a little less variable than the non-inbreds in age at sexual maturity, body weight, and egg weight, and were no different in their winter and annual egg production. The winter and annual egg production was lowered by the use of the inbred males.

Interrelationship of body weight, production, and egg weight, G. W. KNOX, JR. (*Poultry Sci., 13 (1934), No. 4, pp. 227–229*).—Data are given on the relationship of body weight to number and weight of eggs laid by birds of different breeds in the Fifth Georgia Egg Laying Contest, and the Second, Third, and Fourth Louisiana Egg Laying Contests.

Some genetic aspects of hatchability, T. C. BYERLY, C. W. KNOX, and M. A. JULL (*Poultry Sci., 13 (1934), No. 4, pp. 230–238, figs. 8*).—Studies of the incidence and time of embryonic mortality in hatching eggs of the breeding flocks at the U. S. D. A. Animal Husbandry Experiment Farm, Beltsville, Md., showed that, in general, crossing of breeds increased hatchability if the hatchability of the pure breeds was low. This was the result of a decreased mortality during the third week of incubation.

Top-crossing the F_1s on a third breed generally lowered mortality. Inbreeding greatly increased mortality during the third week.

It is concluded that "the inheritance of hatchability must be determined by a very large number of genes, because (1) three lethal genes have already been positively identified; (2) crosses between breeds, both of which have low hatchability, improve hatchability; (3) inherited factors affecting egg quality probably affect hatchability; and (4) inbreeding of itself, in some cases, appears to decrease hatchability."

Creeper and single-comb linkage in the fowl, L. W. TAYLOR (*Jour. Heredity, 25 (1934), No. 5, pp. 205, 206*).—Data from the California Experiment Station showed a linkage of about 0.5 percent between the single-comb and creeper genes in the fowl, confirming Landauer's findings (E. S. R., 69, p. 196).

Congenital tremor in young chicks, F. B. HUTT and G. P. CHILD (*Jour. Heredity, 25 (1934), No. 9, pp. 341–350, figs. 3; abs. in Minnesota Sta. Rpt. 1935, pp. 25, 26*).—A condition designated as congenital tremor in chicks is described by the Minnesota Experiment Station. Of the chicks exhibiting the condition at hatching, 88 percent died before 1 mo. of age. Matings of carrier males and females produced 408 normal and 39 progeny with tremors. It was shown that the condition might be due to the operation of two recessive factors or more probably due to a single recessive autosomal gene so subject to modifying genes that its manifestation is unusually low. Embryonic mortality was not a factor.

An attempt to produce turkey-chicken hybrids, D. C. WARREN and H. M. SCOTT (*Jour. Heredity, 26 (1935), No. 3, pp. 105–107, fig. 1*).—By artificial insemination of a turkey hen with semen from a Rhode Island Red male at the Kansas Experiment Station, there were produced two fertile eggs. One embryo died after a few days of incubation, but the other lived for 22 days during the incubation period. Two other turkey hens produced four and eight fertile eggs after artificial insemination with semen from a White Leghorn male. Only one egg produced by the opposite cross showed signs of fertility. All embryos died before hatching.

The development of the testes and scrotum of the ram, bull and boar, R. W. PHILLIPS and F. N. ANDREWS (*Massachusetts Sta. Bul. 331 (1936), pp. 16, figs. 28*).—The development of the testicle and the tunica dartos muscle of the ram, bull, and boar are described. Spermatozoa first appeared at 147 days of age in the ram, 224 days in the bull, and 147 days in the boar. An increased sensitivity of the dartos muscle to heat occurred as mature sperm were produced. A low plane of nutrition in the boar delayed maturity of the spermatozoa and the development of the temperature regulatory action of the dartos muscle, for which a testicular hormone seems responsible.

Changes in the reproductive organs of the ewe with some data bearing on their control, H. H. COLE and R. F. MILLER (*Amer. Jour. Anat., 57 (1935), No. 1, pp. 39–97, pls. 5, fig. 1*).—A study of the sexual cycle in 55 Southdown, Shropshire, and Hampshire ewes was conducted at the California Experiment Station, and the different stages are described. Significant changes in the hormone content of the ewes' pituitary were noted, but none of the gonadotropic hormones was found in the serum of the pregnant or nonpregnant ewes.

The influence of the gonadotropic hormone and oestrin on different stages of the cycle was studied in 93 7-year-old Romney-Rambouillet ewes. Oestrum and ovulation were induced by doses of 100 rat units of gonadotropic hormones given at 17-day intervals. Oestrin induced oestrum during anoestrum, but when given with the gonadotropic hormone, ovulation was induced without oestrum.

Cytology of the mammary gland of the albino rat, I, II, K. R. JEFFERS (*Amer. Jour. Anat., 56 (1935), No. 2, pp. 257–277, pl. 1; pp. 279–303, pls. 2*).—In part 1, dealing with pregnancy, lactation, and involution, the histological changes in the mammary gland of the rat are described. Part 2, on experimentally induced conditions, deals with a histological study of the mammary glands of rats, indicating their activity following the weaning of the young without nursing, pseudopregnancy induced by suckling, the presence of an inert body in the uterus, hypophysectomy, and the administration of hormones.

The effect of pregnancy on hair growth and shedding in the guinea-pig, D. H. STRANGEWAYS (*Jour. Agr. Sci. [England], 23 (1933), No. 3, pp. 379–382, fig. 1*).—Decreased hair growth and increased shedding occurred during pregnancy, with an increased hair growth following parturition.

The cause of mammary development during pseudo-pregnancy in the rabbit, S. A. ASDELL and G. W. SALISBURY (*Amer. Jour. Physiol., 103 (1933), No. 3, pp. 595–599*).—Initiation of mammary gland development in the pseudopregnant rabbit was found in studies at the [New York] Cornell Experiment Station to originate in the ovaries, independent of coitus or ovulation as determined in several experiments. The stimulus seemed to depend on corpus luteum formation as determined by injections of pregnancy urine.

Effect of experimental hypothyroidism on period of gestation in the rabbit, B. KRICHESKY (*Soc. Expt. Biol. and Med. Proc., 32 (1935), No. 8, pp. 1265–1267*).—Contrary to experiences with the pregnant female rat, it was found in studies at the University of California that thyroidectomy of the pregnant rabbit had no effect on the duration of the gestation period. The decreased oxygen consumption, together with careful microscopic examination, indicated that thyroidectomy was complete in nearly all cases.

A statistical analysis of the interrelations of litter size and duration of pregnancy on the birth weight of rabbits, J. WISHART and J. HAMMOND (*Jour. Agr. Sci. [England], 23 (1933), No. 3, pp. 463–472, pl. 1*).—An analysis of the relation between birth weights, litter size, and duration of the gestation period in three inbred strains of rabbits is reported. These results showed

that the relative influence of size of litter and gestation differs in the three strains. Regression coefficients were calculated for each. The fact that increasing the gestation period from 31 to 35 days showed little or no increase in the weight is considered to be due to the fact that in the last days of pregnancy the maternal placenta undergoes atrophy, which would tend to cut off nutrition to the embryo.

Studies in fertility in the domestic fowl, M. A. JULL (*Poultry Sci., 14 (1935), No. 1, pp. 37–41*).—Studies of the fertility of the eggs produced by the same birds as pullets and yearling hens in the flocks of the U. S. D. A. Bureau of Animal Industry showed greater fertility as pullets for the White Leghorns, Rhode Island Reds, and cross-breds, but greater fertility for yearling hens in the Barred Plymouth Rocks. The fertility of yearlings surpassed 2-year-olds in the White Leghorns and Rhode Island Reds, but Barred Plymouth Rocks as 2-year-olds were more fertile than yearlings. These differences were not great, however.

More fertile eggs were produced with cockerels than with yearlings, but one bird showed greater fertility as a 2-year-old.

A correlation of 0.19±0.05 between the fertility of 111 dams and their 196 daughters was significant and indicated that fertility was inherited.

Studies on the endocrine glands of Frizzle fowl, W. LANDAUER and S. D. ABERLE (*Amer. Jour. Anat., 57 (1935), No. 1, pp. 99–134, figs. 10*).—The results are reported by the [Connecticut] Storrs Experiment Station of the comparative live weights and weights and histology of the thyroids, adrenals, hypophysis, and gonads of male and female homozygous Frizzles and Leghorns subjected to free range and confinement. The testes of the Frizzles showed a much greater relative weight than the Leghorns, but the ovaries of the Frizzles were smaller. At hatching, the thyroids of the Frizzles showed increased activity but differences in the thyroids were observed in the reciprocal crosses between Frizzles and Leghorns. The thyroids of cross-breds with Frizzle dams were smaller and with Frizzle sires were larger. All the abnormalities of the Frizzle fowl are attributed to the defective plumage, resulting in excess loss of body heat.

Reciprocal skin transplants between normals and Frizzles showed no effect of the host on feather structure.

Relation of juvenile plumage to growth and sexual maturity, D. R. MARBLE (*Poultry Sci., 13 (1934), No. 4, pp. 195–201*).—Study of the feather development on the neck, shoulder, dorsal, pelvic wing, thigh, pectoral, and sternal feather tracts in 90 female and 73 male Single Comb White Leghorns from hatching to 20 weeks of age, at the Pennsylvania Experiment Station, showed two peaks of body molt and one complete wing and tail feather molt following the original growth of the feathers, but significant changes in growth rate did not occur during these periods.

Analyses of data on 387 pullets indicated a tendency of early-maturing pullets to carry over one or more chick feathers during the first laying year, but also indicated the impossibility of forecasting date of first egg by primary feather development at 8 or 10 weeks of age.

Interactions of gonad stimulating hormones in ovarian development, H. L. FEVOLD and F. L. HISAW (*Amer. Jour. Physiol., 109 (1934), No. 4, pp. 655–665*).—In studies at the University of Wisconsin, the influence of the follicle-stimulating and luteinizing hormones of the pituitary on the ovaries of immature rats was found to be greatly enhanced by the injection of these substances in combination. Pregnancy urine extract had a similar effect on the luteinizing hormone in combination with the follicle-stimulating hormone. It

is considered that the greater action of the combined hormones was due to separate functions performed by each hormone in sequence, and that there was no evidence of a separate synergystic factor.

An improved method for separating and purifying the follicle-stimulating and luteinizing hormones of the hypophysis is outlined.

The alleged interrelationship of the adrenal cortical hormone and the gonads, R. GAUNT and W. M. PARKINS (*Amer Jour. Physiol., 103 (1933), No. 2, pp. 511–516, figs. 6*).—Treatment of immature rats and chickens over long periods with cortical hormone produced no effect on the reproductive systems.

An improved method for determination of the gonadotropic hormone, U. J. SALMON and R. T. FRANK (*Soc. Expt. Biol. and Med. Proc., 32 (1935), No. 8, pp. 1236, 1237*).—The details of an improved method for the detection of gonadotropic hormone in human blood are described, based on examination of serial sections of the ovaries of immature rats injected with the extracts.

Studies on the physiology of lactation.—II, Lactation in the male guinea pig and its bearing on the corpus luteum problem, W. O. NELSON and G. K. SMELSER (*Amer. Jour. Physiol., 103 (1933), No. 2, pp. 374–381*).—Continuing this series (E. S. R., 68, p. 181), castrate and experimental cryptorchid male guinea pigs with functional ovarian grafts or following oestrin administration were induced to lactate with the administration of extracts of the anterior lobe of the hypophysis. Luteal influence did not seem necessary for lactation.

The effects of prolonging the life of the corpus luteum in the rabbit by hysterectomy, S. A. ASDELL and J. HAMMOND (*Amer. Jour. Physiol., 103 (1933), No. 3, pp. 600–605*).—A study of the retention of corpora lutea in pregnant, pseudo-pregnant, and hysterectomized rabbits showed that corpora lutea of hysterectomized rabbits retain their size and ovulation-inhibiting function about 10 days longer than pesudo-pregnant rabbits, but 6 days less than pregnant rabbits.

The relation between the endocrine glands and the oestrus cycle.—Second report, S. TSUCHIMOTO (*Japan. Jour. Expt. Med., 13 (1935), No. 1, pp. 59–62*).—The influence of injections of emulsions of the pituitary, thymus, thyroid, suprarenal, pineal body, ovary, testes, liver, spleen, kidney, lung, and muscle from cattle on the oestrous cycle of the albino rat was studied at the Tokyo Imperial University.

Extraction of estrin from female urine after acidification with various acids, W. K. CUYLER (*Soc. Expt. Biol. and Med. Proc., 32 (1935), No. 8, pp. 1352–1357*).—Studies of the influence of different acids on the extraction of oestrin from urine showed that the greatest yield was produced when tartaric acid was used, whereas smaller amounts were obtained by the use of trichloracetic, glacial acetic, hydrochloric, and sulfuric acids.

Effect of oestrin on ovaries and adrenals, H. SELYE, J. B. COLLIP, and D. L. THOMSON (*Soc. Expt. Biol and Med. Proc., 32 (1935), No. 8, pp. 1377–1381, fig. 1*).—The administration of oestrin to pregnant and lactating rats prolonged the life of the corpora lutea and, in the pregnant animals, interfered with parturition. The normal presence of oestrin during pregnancy and its absence during lactation are considered to be responsible for the differences in the ovaries, endometrium, and vaginal epithelium of normal pregnant and normal lactating rats.

Continued large doses of oestrin to adult rats resulted in an initial appearance of vaginal oestrum followed by a prolonged dioestrum with enlarged ovaries, but after three weeks vaginal oestrum reappeared and the ovaries returned to normal.

Oestrin did not lead to enlargement of the pituitary or adrenals except in the presence of corpora lutea and, therefore, did not occur in males. It

was impossible to prevent involution of the mammary gland, following hypophysectomy, by the administration of oestrin.

The general conclusion reached in these studies was that "animals whose ovaries have been depressed by oestrin treatment do not respond normally to A. P. L. administration, while on the other hand corpora lutea produced by the action of A. P. L. are enlarged by concurrent and subsequent oestrin treatment."

The continued injection of oestrin into young rats, G. PINCUS and N. WETHERSEN (*Amer. Jour. Physiol., 103 (1933), No. 3, pp. 631–636, fig. 1*).—Continued injections of oestrin into young rats caused an inhibition of ovarian growth and some thyroid hypertrophy but was without effect on the size of the pituitary.

Reactions of ant. pituitaries of male rats to administration of ant. pituitary-like substance and to oestrin, J. M. WOLFE and D. PHELPS (*Soc. Expt. Biol. and Med. Proc., 32 (1935), No. 8, pp. 1305–1309*).—The comparative effects on pituitary, testes, prostate, and seminal vesicle weights and cell types in the pituitary of 10 daily administrations of follutein (an extract of the anterior pituitary lobe substance or pregnancy urine) and oestrin (progynon-B) to adult rats were studied at Vanderbilt University. The oestrin injections increased the weight of the pituitary and caused loss of granules from the basophiles and eosinophiles comparable to the combined effects of oestrin and the anterior pituitary lobe factor on normal immature female rats. Injections of the extract from pregnancy urine caused only a loss of granules from the basophiles.

The inhibition of lactation in rabbits with large amounts of oestrin, G. VAN S. SMITH and O. W. SMITH (*Amer. Jour. Physiol., 103 (1933), No. 2, pp. 356–361*).—The administration of large doses of oestrin to postpartum does inhibited milk secretion as in rabbits with retained placental remnants.

FIELD CROPS

[Field crops research in Florida] (*Florida Sta Rpt. 1935, pp. 36–42, 43–45, 46, 47, 61, 109, 114, 116, 117, 118–123, 128, 130, 136, 138, 139, 145–148, fig. 1*).—Continued progress was reported from agronomic investigations (E. S. R., 73, p. 160) at the station and substations, carried on by F. H. Hull, W. A. Carver, W. E. Stokes, G. E. Ritchey, J. P. Camp, J. H. Jefferies, W. A. Leukel, J. D. Warner, R. W. Ruprecht, A. Duane, B. A. Bourne, F. D. Stevens, R. V. Allison, R. E. Robertson, J. R. Neller, G. R. Townsend, R. R. Kincaid, H. S. Wolfe, and W. M. Fifield, and concerned with breeding work with corn, sweet corn, sugarcane, and peanuts; attempts to induce bud variations in sugarcane artificially; variety tests with corn, oats, grain sorghum, sorgo, potatoes (also seed sources), cowpeas, soybeans, alfalfa, clover, sweetclover, lespedeza, vetch, and miscellaneous forage and pasture grasses and legumes and cover crops; production tests with ramie and seed and fiber flax; fertilizer tests with corn, oats, potatoes, chufas, Dallis grass, and Napier grass; the carbohydrate fractions of field and sweet corn; response of corn to several of the less abundant elements, especially zinc; green manure studies; a study of the development and deterioration of roots in relation to the growth of pasture plants grown under different fertilizer and cutting treatments; effects of different rates and carriers of nitrogen on pasture grasses; dates and rates of planting, stage of cutting, and methods of haymaking, all with *Crotalaria intermedia;* relation of organic composition of crops, e. g., sugarcane, grasses, and forage legumes, to growth and maturity; the relation of manganese and other less abundant elements to potato yields

on glade soils; the effectiveness of treatment of potato seed tubers for control of tuber diseases; cultural tests with potatoes and chufas; preliminary stack silo experiments with surplus sugarcane; comparative production of silage crops, including corn, pearl millet, sorgo, Napier grass, and Cayana sugarcane when grown at relatively high fertility levels; cutting tests with alfalfa; seed storage investigations; methods of producing seed in the field, germination of seed after 3 yr. in storage of different types, and factors involved in seedling production, all with tobacco; corn and peanuts rotating with crotalaria and with native cover crops; and crop rotation studies with corn, cotton, crotalaria, and Austrian winter peas Pasture studies included effects of different fertilizer formulas on yields of pasture grasses; comparisons of native v. improved and burned v. unburned native pastures and of methods of preparing land for seeding; and pasture studies on peat and muck soils. Several lines of work were in cooperation with the U. S. Department of Agriculture.

[Field crops experiments in Idaho, 1935], H. W. HULBERT, H. L. SPENCER, J. TOEVS, W. H. MOSS, and R. KNIGHT (*Idaho Sta. Bul. 220 (1936) pp. 16–19, 47–49, 50, 51–53, 56–58, 59–61, figs. 7*).—Field crops research (E. S. R., 74, p. 27) reported on from the station and substations included breeding work with wheat, barley, oats, sugar beets, field peas, Ladino clover, sweetclover, and slender wheatgrass; variety tests with oats, winter and spring wheat and barley, sugar beets, alfalfa, red clover, field peas, potatoes, sweet corn strains, and miscellaneous forage grasses and legumes and mixtures; cultural (including planting) trials with field peas and brome grass; an irrigation experiment with red clover; response of field pea varieties to alfalfa in the rotation; fertilizer tests with alfalfa, wheat, and potatoes; treatment of alfalfa with gypsum; and crop rotations. Activities of the State seed laboratory are also reviewed. Certain lines of work were in cooperation with the U. S. Department of Agriculture.

[Field crops work in Michigan] (*Michigan Sta. Rpt. 1935, pp. 220, 221*).—Brief reports are given on results of breeding work with beans, oats, peppermint, corn for resistance to European corn borer, and potatoes; pasture experiments, including response to fertilizers and alfalfa and mixed pasture for poultry; cutting tests with alfalfa in relation to fall weather; sweetclover as green manure for beans; effect of preceding crops and seedbed preparation on sugar beets; and irrigation and planting tests with potatoes.

[Agronomic experiments in Montana] (*Montana Sta. Rpt. 1934, pp. 27–35, 36, 54–56, 59–64, 69–71, figs. 6*).—Accomplishments in research with field crops at the station and substations are reviewed. The several experiments and activities included breeding work with wheat and oats, and introduction, testing, and distribution of improved varieties of barley, rye, oats, and alfalfa, and crested wheatgrass; response of alfalfa, sweetclover, barley, wheat, oats, sugar beets, and potatoes to phosphorus; crop rotations on dry land and under irrigation; response of corn to continuous culture; methods of preparing and cultivating fallow; benefits of fallow in growing small grains on dry land; regrassing cultivated dry land areas by reseeding with improved grasses and grazing tests thereon; irrigated, manured pastures; classification of agricultural land; and testing of seed for purity and germination and wheat for smut dockage and protein content. Certain lines of work were in cooperation with the U. S. Department of Agriculture.

[Field crops investigations in New Jersey] (*New Jersey Stas. Rpt. 1935, pp. 14–18, 32, 33*).—Brief progress reports are made on agronomic research (E. S. R., 73, p. 170), including breeding work with corn, rye, timothy, red and alsike clover, alfalfa, and artichokes; inheritance of tolerance by alfalfa to soil conditions; variety tests with corn, wheat, oats, barley, seed flax, soybeans for grain and hay, cowpeas, red clover, and annual hay crops; increasing the

protein content of timothy by nitrogen fertilization at heading; pasture experiments concerned with the value of 22 seeds mixtures in conjunction with 8 systems of fertilization, the relation between time of liming and the response of pastures to phosphate, and management of rotated pasture; and experiments on establishing and maintaining turf.

[Agronomic research in South Dakota], A. N. HUME (*South Dakota Sta. Rpt. 1935, pp. 11–13, 14*).—Progress notes are made on field crops investigations (E. S. R., 73, p. 170), including breeding work with durum and common spring and winter wheats, barley, and oats, and effect of phosphorus on early maturity in corn.

Irrigated crop rotations in western Nebraska, 1912–34, S. H. HASTINGS (*U. S. Dept. Agr., Tech. Bul. 512 (1936), pp. 36, figs. 4*).—Results from a comprehensive series of rotation experiments conducted at the Scotts Bluff (Nebr.) Field Station on the North Platte reclamation project are reported for the period 1912–34, supplementing earlier accounts (E. S. R., 58, p. 30; 74, p. 186). The environmental conditions and technic are described and crop yields are set forth in detail.

Determination of annual fluctuations in yields for the crops showed the highest annual mean percentage (1926–34) to be 134 in 1928 and the lowest 52 in 1934. On the basis of periods, the highest percentage, 122, was for the 6 yr. 1912–17, and the lowest, 77, in the last 5 yr., 1930–34.

Oats made their highest mean yields in manured alfalfa rotations, and their lowest yields came from continuous oats and from 2-yr. untreated rotations. Sugar beet yields were the most favorably influenced by manure and by harvesting one or more crops in a rotation by livestock, whereas the increases due to alfalfa were smaller. Contrary to the results with sugar beets, alfalfa had a more favorable influence than manure on potato yields. The highest mean yields of potatoes were harvested from two 6-yr. alfalfa rotations and were followed by yields from two manured alfalfa rotations and from two 4-yr. alfalfa rotations. The lowest percentages of cull potatoes were harvested from the rotations including alfalfa and the highest from the continuously cropped plats. Due to the type of rotations, wheat yields were quite low, the highest mean yield, 27.4 bu. per acre, for the 23 yr. being harvested from a 4-yr. alfalfa rotation. Yields of corn distinctly exceeded wheat yields, the highest mean yield of corn, 55.7 bu., coming from a 6-yr. alfalfa rotation.

The comparative values of several rotations as complete units are tabulated and discussed. The highest net return came from the manured rotation devoted to sugar beets and potatoes, the chief cash crops of the area, and the next highest return was from a pastured rotation. Of the eight rotations indicating a net return of $19 or more per acre, five of them received applications of manure, one included pasturing, and the other two were alfalfa rotations.

A comparison of soil moisture under continuous corn and bluegrass sod, G. R. FREE (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 359–363, fig. 1*).—Soil moisture in a 3-ft. profile under continuous corn significantly exceeded that under bluegrass sod in spite of a difference in run-off of 5.51 surface inches. This difference in available moisture could not be accounted for by greater additions to subsoil moisture below the 3-ft. profile, because the percolation under corn in the period for which percolation data from lysimeters is available was greater by 3.62 surface inches. This condition of less run-off and less soil moisture under bluegrass sod as compared with corn could only be explained by the greater evaporation and transpiration losses for bluegrass.

Varietal resistance of small grains to spring frost injury, J. B. HARRINGTON (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 374–388*).—A widespread frost

occurring June 4, 1935, at Saskatoon, Sask., caught most of the cereal breeding and testing nurseries of the University of Saskatchewan when the seedlings were in the critical two-leaf stage. Highly significant differences in frost injury were found among the wheat, oat, barley, and flax varieties commonly grown in western Canada as well as in the new hybrid varieties. Certain varieties were injured badly while others showed high degrees of frost resistance. The results in different nurseries, even where they were 1,000 ft. apart, were very consistent. Susceptibility to frost was particularly noticeable in varieties having a large amount of warm-climate ancestry, whereas varieties having mostly cold-climate ancestors were frost resistant.

Combine investigations with spring wheat and oats, H. K. WILSON (In *Proceedings of the World's Grain Exhibition and Conference, Regina, Canada, 1933. Ottawa: Canad. Soc. Tech. Agr., 1933, vol. 1, pp. 468–469; abs. in Minnesota Sta. Rpt. 1935, p. 14*).—Varieties of spring wheat and of oats were grown at the Minnesota Experiment Station in rod rows during the period 1930–32, which was unusually dry, averaging 4.4 in. of rainfall below normal. Row harvests were made when the grain was considered in a proper stage for binder harvesting and at 4, 8, and 14 days thereafter, and harvested samples were threshed at once.

Each of the 14 spring wheats maintained yields throughout the 2 weeks. While most of the 12 oats varieties suffered reduction in yield, Anthony, a midseason oats, maintained its yield level throughout the trials and appeared most promising for combine harvesting. Grain quality, as evidenced by plumpness of both wheat and oats and texture of wheat, usually increased to 8 days after the normal binder harvesttime. Since moisture conditions during the period were abnormally low for the station, the results probably were more nearly typical of those expected in dry farming areas of the Dakotas, Montana, and Canada.

Pasture investigations.—VIII, Modifying the seasonal growth habits of grasses, B. A BROWN and R. I. MUNSELL ([*Connecticut*] *Storrs Sta. Bul. 209 (1936), pp. 22, figs. 7*).—The eighth of this series (E. S. R., 75, p. 332) reports the seasonal and total yields obtained, 1932–35, from variously fertilized, grazed permanent pastures and mowed plats of Kentucky bluegrass and Rhode Island bent cut when 2, 3, 4, and 5 in. high. Certain effects of the fertilizer on the chemical and botanical compositions of the herbage are also noted.

Prevalence of volunteer white clover was greatly reduced on the mowed plats by nitrogen (71 percent from ammonium sulfate and 29 from sodium nitrate), especially when applied in April, June, and August. Of the single applications, June nitrogen was the most effective in discouraging clover. Frequent cutting also retarded the spread of clover. Based on total yields, April nitrogen was about twice as effective as June or August nitrogen. The effectiveness of nitrogen decreased with repeated treatments and increased with increases in the height of the grasses when cut. June and especially August nitrogen reduced the responses to April nitrogen, but April or June nitrogen did not decrease the stimulative effects of August nitrogen. The phosphorus-potassium plats, with 38 percent of volunteer white clover, yielded nearly as much as any plat treated with nitrogen.

The seasonal habits of growth of both grasses were modified markedly by nitrogen. The usual zenith period from May 16–June 15 was postponed a month by nitrogen at 56 lb. in June, and was changed to August 16–September 15 by the same amount of nitrogen in August. April nitrogen at either 28 or 56 lb. per acre exerted most of its influence on yields before June 16 and accentuated the May–June peak. The total and seasonal yields as measured

by grazing or cutting agreed quite closely for a given fertilizer treatment. Frequent cutting leveled the seasonal, but decreased the total yields. Grass grew slowest in the period after September 15. The 3-in. cutting with nitrogen in April, June, and August produced the best lawn.

The height of cutting had more influence than nitrogenous fertilizers in changing the nitrogen content of mowed Kentucky bluegrass. Decreasing the clover in the turf with nitrogenous fertilizers resulted in a decrease in nitrogen in the herbage, especially with the higher cuts. The herbage from the grazed pastures contained appreciably more nitrogen than the mowed grass, even that cut when 2 in. high.

Need and use of potash on Vermont pastures, A. R. MIDGLEY and V. L. WEISER (*Vermont Sta. Bul. 403 (1936), pp. 18, pls. 4*).—The need of Vermont pasture soils for potash was determined by chemical soil tests (E. S. R., 72, p. 15), and plant response in greenhouse and field plat studies on the major soil types, and ways of using potash most economically were ascertained by determining potash fixation and crop growth with different rates of application. The soils involved in the several tests included Woodbridge, Berkshire, Worthington, Ondawa, Merrimac, and Colrain sandy loams; Woodbridge, Vergennes, Ondawa, and Calais clay loams; Pittsfield sandy clay loam; and Addison, Mohawk, and Vergennes clay.

While the clay soils of the Champlain Valley were about the only ones in Vermont shown by the chemical studies to have a high content of and perhaps enough potash, certain crops on these soils have shown a good response to additional potash provided clover is predominant. This seems significant because clovers need much more potash than do pasture grasses. Most Vermont pasture soils appeared able to fix much potash into unavailable forms, particularly the A_2 horizon of podzolized soils. Since colloidal silicates seem responsible for potash fixation (conversion to muscovite), and since the A_2 horizon is high in siliceous material, it may be a source of fixation in Vermont soils.

Although grasses usually responded to small applications of potash salts, e. g., 75 to 100 lb. of potassium chloride, heavier applications often resulted in decreased yields. However, pasture clovers continued to respond to each increment of potash. Since plant response to added potash depends upon the amount of white clover present, means of maintaining and increasing the growth of this desirable plant in pastures are discussed.

Growing pastures in the South, J. F. COMBS (*Chapel Hill: Univ. N. C. Press, 1936, pp. IX+270, figs. 78*).—"This book is sent forth with the hope that it may be the means of creating a greater interest in the important program of pasture improvement, and that it may furnish reliable information on how to develop pasture areas into profitable grazing lands. The author has undertaken to assemble the recommendations of experts throughout the South, based on experimental data, and to combine them with his own personal observations over a period of many years."

Practical information is given on the characteristics, adaptation, and uses of the pasture grasses and legumes; pasture establishment, fertilization, management, and utilization; inoculation of legumes and weed control; and on suitable pasture crops and mixtures for each of the Southern States.

Feeding turf grasses on lawns, parks, and recreation fields, H. B. SPRAGUE (*New Jersey Stas. Circ. 365 (1936), pp. 4*).—Popular information is given on the functions and sources of essential plant nutrients, suitable fertilizer formulas, and the most effective times and methods of applying fertilizers for turf grasses on different soils.

Phosphate for alfalfa, H. N. WATENPAUGH and G. STATEN (*New Mexico Sta. Bul. 239 (1936), pp. 8, fig. 1*).—Fertilizer tests (E. S. R., 50, p. 232) with alfalfa

on Gila clay loam, 1919–35, indicated the need of alfalfa for phosphate but not for other fertilizers. Applications of 45 percent superphosphate, 135 lb., applied each year and 180 lb. applied in alternate years, were the most profitable, considering the return per dollar invested in fertilizer and the increase in value of hay less cost of fertilizer. Where only a limited amount can be expended for phosphates, application in alternate years gives the largest return per dollar invested, although this may not give the highest economic return per acre.

Studies of the culture and certain varieties of the Jerusalem artichoke, V. R. BOSWELL, C. E. STEINBAUER, M. F. BARR, W. L. BURLISON, W. H ALDERMAN, and H. A. SCHOTH (*U. S. Dept. Agr., Tech. Bul. 514 (1936), pp. 70*).—Cultural and varietal investigations with Jerusalem-artichokes were made, 1931–33, near Washington, D. C., and at Urbana, Ill., Excelsior, Minn., Corvallis, Oreg., and Cheyenne, Wyo., in cooperation with the Illinois, Minnesota, and Oregon Experiment Stations. See also earlier notes (E. S. R., 58, p. 226; 68, pp. 321, 322).

Three of 20 varieties grown in Illinois, Oregon, and near Washington, D. C., for 3 yr., i. e., Nos. 27574, 27095, and 27007, were outstandingly superior in yield in all locations. High yielding varieties tended to be so in all locations and the converse held true, but the order of superiority was not identical. Although analyses of levulose content of hundreds of stocks and varieties made in cooperation with the National Bureau of Standards showed a high negative correlation between tuber yielding capacity and levulose content, the highest yielding variety, No. 27574, showed the highest 6-yr. mean percentage of levulose and total sugars of the 20 varieties under test.

Each successively larger seed piece from 0.25, 0.5, and 1 to 2 oz. in weight, compared in Minnesota and Wyoming and near Washington, D. C., produced successively larger net yields, while in Oregon seed pieces over 2 oz. did not outyield 2-oz. pieces. Increase in size of seed piece was consistently accompanied by increase in number of stalks per hill but not by increase in mean size of tuber harvested.

Since marked decreases in yield usually came from every planting made after the earliest one (except near Washington where April plantings did not differ significantly), the earliest possible planting is advised regardless of variety or location. Effect of time of planting on size of tubers harvested was comparable with that on yield, i. e., if yield is depressed by delayed planting so is mean tuber size.

A slight but consistent difference was found in favor of the 4-in. planting depth over the 3-, 5-, or 6-in. depth in the humid regions. In the Wyoming tests only (irrigated) did the 5-in. surpass the 4-in. depth, and here planting depth apparently did not affect depth of stolon origin. Near Washington, D. C., however, successively deeper plantings resulted in successively greater percentages of the stolons arising from the stem below a 4-in. depth. While depth of planting did not affect size of tubers harvested, it markedly affected depth of tubers harvested near Washington, D. C. Successively deeper plantings resulted in successively deeper tuber formation. Few tubers were found below 6 in. but the percentage of total harvest that came from the 4- to 6-in. soil zone increased significantly with deeper planting.

In general, the 12-in. spacing between hills outyielded the 18-, 24-, 30-, or 36-in. plantings, while in Oregon 2-, 3-, and 4-ft. spacings yielded equally well. The 12-in. spacings produced tubers of lower mean weight than the wider spacings, but there were no differences among the others. Pending further information, spacings of 2 ft. in the row are suggested except for conditions resembling those of the Oregon tests, where 4 ft. seems adequate. The highest acre yields with plants 2 ft. apart in the rows came from the 3-ft. row distance

in all locations except Oregon, where 4-, 5-, and 6-ft. row spacings with plants 4 ft apart did not differ significantly. In all locations, as distances between hills or between rows were increased, the number and yield of tubers per hill increased.

The maximum yields of green tops were obtained by harvesting just before blossoming, and of dry matter of tops just after blossoming. Top harvesting delayed beyond blossoming resulted in great losses of both green and dry matter due to dropping of leaves and also, possibly, very marked food translocation to the tubers. Ultimate tuber yields are reduced 65 to 75 percent when tops are harvested early enough for maximum green weight, 40 to 60 percent with tops harvested for maximum dry weight, and about 30 percent with the very latest top harvest for forage of medium quality and yield. Crude fiber in the tops gradually increases in percentage of fresh weight, from the earliest probable top harvest until leaf fall begins, after which a much more rapid increase occurs. On the dry-weight basis, crude fiber remains nearly constant from the earliest harvested tops until appreciable leaf fall and then increases greatly. That satisfactory yields both of tops for forage and of tubers can be obtained from the same plants seemed improbable.

For control of volunteer growth, deep, thorough, late spring or early summer plowing after such growth is about 1.5 ft. high has been very effective, particularly if followed at once by a quick-growing hay crop to shade out the few surviving sprouts. Survivors should be hand-pulled or destroyed, incidental to the hay harvest, before tuber formation in August.

Growing the Jerusalem artichoke, V. R. BOSWELL (*U. S. Dept. Agr. Leaflet 116 (1936), pp. 8*).—The information given on the adaptation, varieties, and soil, fertility, cultural, and harvesting requirements of Jerusalem-artichokes, and the cultural recommendations are based largely on the research reported above.

Prediction of double cross yields in corn, C. W. DOXTATOR and I. J. JOHNSON (*Jour Amer. Soc. Agron., 28 (1936), No. 6, pp. 460–462*).—Results obtained in corn breeding experiments by the Minnesota Experiment Station indicated that highly significant differences in yielding ability can be found in double crosses resulting from the use of different single cross parents produced from four inbred lines. There were also indications that by the appropriate use of single cross data, the highest yielding double cross combination may be predicted.

Results from the cooperative coordinated oat breeding nurseries for 1935 and the uniform winter-hardiness nurseries for 1935–36, together with summary of data for previous years, compiled by F. A. COFFMAN (*U. S. Dept. Agr., Bur. Plant Indus., 1936, pp. 95, fig. 1*).—The yields and winter hardiness data reported were secured in cooperative studies made in 81 localities in 32 States.

Potato experiments, J. BUSHNELL, D. COMIN, and J. P. SLEESMAN (*Ohio Sta. Spec. Circ. 48 (1936), pp. 60–66, figs. 3*).—The potato studies reviewed briefly dealt with the merits of standard and new varieties and of Ohio potatoes for seed; dates of planting and type of sprouting of seed potatoes; exposure of cut seed; size of seed; response to manure and to aeration of soil; corn and rye as green manures; depth of rooting of potatoes; and variety, cultural, fertilizer, and irrigation experiments with potatoes on muck soil.

Grain sorghum production relative to planting date and row spacing, H. H. FINNELL ([*Oklahoma*] *Panhandle Sta., Panhandle Bul. 60 (1936), pp. 19*).—The stands, total dry matter, and grain yields are reported for 10 grain

sorghum varieties grown on Richfield silt loam at Goodwell, Okla., planted late in May and early and late in June in 3.5- and 7-ft. rows during the period 1924–33. Field conditions prevented planting at certain times in several years See also a previous note (E. S. R., 69, p. 514).

Spur feterita averaged one-fourth stand when planted in May and about one-half stand in June, while hegari averaged slightly better from these plantings. Desert Bishop produced slightly over one-half stand when planted in May and from two-thirds to three-fourths stand planted in June. Dwarf Yellow milo averaged slightly better stands as the season advanced. Pink kafir and the Fargo, Beaver, and Double Dwarf milos showed little consistent difference in stands secured from different planting dates. The average stand of darso at different dates was very consistent throughout the planting season. The stands for the 10 varieties for the 3 plantings averaged 64, 78, and 70 percent, respectively.

The total yield increased with lateness of planting to the late June date for Dwarf Yellow milo, darso, Spur feterita, and Desert Bishop, and decreased for Pink kafir. The highest total yield was produced from early June planting by Dawn kafir and hegari. Slightly irregular relations of total yield to planting dates were noted for Dawn kafir and the Fargo, Beaver, and Double Dwarf milos. The percentage of total yield produced as grain was consistently higher for Pink and Dawn kafirs, darso, Desert Bishop, and Fargo milo in wide-spaced rows, but the highest grain yield from wide spacing was made only by darso and Pink and Dawn kafirs, 3 varieties for which early June also was the most favorable planting date. The highest grain yields came from 3.5-ft rows planted in early June for Desert Bishop and Fargo milo and from 3.5-ft. rows planted in late June for Spur feterita and the Dwarf Yellow, Fargo, Beaver, and Double Dwarf milos. In grain production, darso, Dawn kafir, and Desert Bishop were relatively unaffected by variation in planting date and row spacing. The fact that the Dwarf Yellow, Beaver, and Double Dwarf milos and Pink kafir appeared to be rather sensitive to these factors indicated that best results depended upon the accurate placement of planting date and control over the stands obtained.

The time of planting most suitable for maximum grain production was a date as late as possible to allow the variety adequate time to mature before frost. Wide spacing as a systematic practice produced a larger average grain yield only from tall-growing relatively late-maturing varieties seldom used for grain production because of their low yield.

Variety tests of sugarcanes in Louisiana during the crop year 1933–34 and summary of annual results 1926–34, G. ARCENEAUX, I. E. STOKES, and C. C. KRUMBHAAR (*U. S. Dept. Agr. Circ. 395 (1936), pp. 31, figs. 3*).—Sugarcane variety tests with commercially grown and new varieties (E. S. R., 73, p. 472) were made in the crop year 1933–34 and included plant cane and first and second stubble tests on light and heavy soils, plant cane and first stubble on muck soil and fiber determinations. A summary of annual results obtained, 1926–34, is also presented. Many of the data largely confirm conclusions drawn from previous tests.

"There appears to be no reason for the continued extensive cultivation of the varieties P. O. J. 36, P. O. J. 36–M, P. O. J. 213, and P. O. J. 234. Co. 290 has consistently surpassed, by extremely wide margins, yields of sugar per acre obtained with either P. O. J. 36, P. O J. 36–M, or P. O. J. 213 and has proved rather consistently superior to all of them in yield of sugar per ton of cane. The results of all tests now available indicate that C. P. 28/19 will be a much more satisfactory variety than P. O. J. 234 for early milling. C. P. 807 and

Co. 281 have also demonstrated qualities generally superior to those of P. O. J. 36, P. O. J. 36–M, and P. O. J. 213."

Previous estimates of C. P. 28/19 were fully confirmed. The extremely high yields of sugar per ton of cane and generally satisfactory yields of plant cane and first and second stubble render it very valuable for Louisiana cultivation in general, and particularly for early milling. Its superiority to P. O. J. 234 in yield of sugar per ton of cane at any harvest date was demonstrated conclusively. It has quite generally given sugar yields per acre exceeding comparable yields from C. P. 807. Indications were that C. P. 28/19 will be satisfactorily adapted to conditions presenting difficult maturity problems, as on reclaimed muck soils and on the Red River and Atchafalaya bottom soils in central Louisiana. C. P. 28/11 appears to be definitely inferior to C. P. 28/19 in yield of sugar per acre and per ton of cane. The merits of other recent canes are also discussed briefly.

The effect of nitrogen on cane yield and juice quality, U. K. Das and A. H. Cornelison (*Hawaii. Planters' Rec.* [*Hawaii. Sugar Planters' Sta.*], *40 (1936), No. 1, pp. 35–56, figs. 12*).—In a preliminary study, 1933–35, of the effect of nitrogen fertilization on the yield and composition of sugarcane, low, medium, and high levels of nitrogen, i. e., 133, 266, and 645 lb. per acre, respectively, supplied by ammonium sulfate, and each supplemented by phosphoric acid 200 lb. from superphosphate and potash 200 lb. from potassium sulfate, were applied to H 109 cane grown outdoors in plats at Honolulu. See also an earlier note (E. S. R., 71, p. 769).

Increase in nitrogen application was accompanied by increases in tiller production, leaf and joint formation, elongation, cane tonnage (which may be lessened by top mortality), lodging, succulence (water content), reducing sugars, nitrogen content of tissue, and electrical conductivity of juice, and by decreases in sucrose. The highest amount of sucrose was obtained from moderately high application of nitrogen, as in the medium levels. "Increasing applications of nitrogen appear first to increase the salt absorption by the plants, the increased salt content probably causing greater water content or succulence of tissue. The greater water content has a diluting effect on juice resulting in a lower concentration of sucrose. This increased water content may even favor the storage of sugars such as glucose at the expense of sucrose."

Nitrogen nutrition of sugar cane, U. K. Das (*Plant Physiol., 11 (1936), No. 2, pp. 251–317, figs. 23*).—A more technical account of the above research.

Selection of open-pollinated timothy, M. W. Evans (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 389–394, figs. 4*).—Certain features of the timothy breeding investigations by the U. S. D. A. Bureau of Plant Industry, cooperating with the Ohio Experiment Station at North Ridgeville, Ohio, are described. The high variability in commercial timothy has made possible by continuous selection through several generations the development of strains having longer stems, earlier or later maturity, and better retention of green color in the leaves than the plants from which they were derived. The plants of many of these new strains, e. g., Huron (E. S. R., 70, p. 179), show a high degree of uniformity even though grown under natural conditions permitting open pollination.

Sowing timothy in thin alfalfa stands, C. J. Willard (*Ohio Sta. Bimo. Bul. 181 (1936), pp. 93–95*).—Timothy sown in thin alfalfa meadows at the rate of about 5 lb. per acre after the last fall cutting, either by drilling without other preparation or by preparing a seedbed with the spring-tooth harrow or disk and then broadcasting or drilling the seed, has increased decidedly the amount of hay at the first cutting and decreased the percentage of weeds present.

Hairy vetch in Ohio, C. J. WILLARD (*Ohio Sta. Bimo. Bul. 181 (1936), pp. 87–92, figs. 3*).—The merits and uses of hairy vetch in Ohio are discussed, with recommendations for growing vetch in mixtures with wheat and rye for hay or green manure and alone for seed production, based on results of planting and harvesting tests and protein determinations made at Columbus since 1919.

Tensile strength, extensibility, and other characteristics of wheat roots in relation to winter injury, C. A. LAMB (*Ohio Sta. Bul. 568 (1936), pp. 44, figs. 7*).—Studies on the size, breaking tension, and extensibility of the roots of 15 varieties of winter wheat were carried on at the station and at Cornell University. Attention also was paid to the number and characteristics of roots and the influence of the soil fertility level. The data were analyzed in efforts to correlate winter behavior with the physical measurements and thus to indicate a basis upon which to discard undesirable lines early in the breeding program and to conserve valuable material.

Size of root, which may be related to strength and to resistance to desiccation, is considered of importance. Extensibility of roots varies among varieties, the more heaving-resistant having the greater stretching capacity. Breaking tension of the root is held very important because it may be sufficient to prevent root breakage so near the surface when the crown is actually pulled up by frost action. In soils with very large capillary pores, where undercooling is only slight, strong roots actually may prevent the heaving up of the crown. Other factors which may have a part in determining reaction to heaving are the number and type of roots, whether they are profusely branched or not and at what distance below the surface branching begins, as well as size of cells in the vascular tissue and the proportion of vascular system to cortex.

Tests on plants grown at different fertility levels indicated that the total development and also the type of development may be influenced by the supply of nutrients and the ratios existing among the elements, especially available nitrogen, phosphorus, and potassium. In any case, well-developed, vigorous plants in the fall evidently are essential to maximum resistance to spring heaving injury. Indications were that varieties differ markedly in their ability to continue growth at a relatively high rate as conditions become increasingly adverse with approach of winter. Cold-resistant wheats stop growth first, whereas varieties most resistant to heaving continue to grow longest.

A definite antagonism is evident between cold resistance and heaving resistance, although there has been no indication that, for Ohio conditions at least, a wheat could not be developed that would be cold resistant enough to withstand ordinary winters and at the same time be highly resistant to heaving. Gladden does not fall far short of this ideal.

The ranking of the several varieties on winter behavior is discussed in the light of opinions of workers in other States. Purplestraw, well adapted farther south, lacks cold resistance when grown in Ohio. It has heaving resistance but lacks the ability to survive low temperatures and has found its place in regions where wheat is seldom killed by cold. Leap and Red May probably belong to the same group. Minhardi and Kharkov, very resistant to low temperatures but readily injured by heaving, are adapted to the Great Plains where winter temperatures are severe and heaving injury is practically nonexistent because of soil moisture conditions. The newer varieties, adapted to the region in which developed, have size and strength of root proportional to the probability of heaving damage, as indicated by weather data. Cold resistance is likewise sufficient for the particular location.

Although considered as preliminary in certain respects, the studies are held to indicate that "certain root measurements vary markedly with variety and with the resistance of the variety to cold and to heaving injury. Observations combined with the results of the experiments further indicate that no one characteristic of the roots alone is an entirely satisfactory measure of ability to resist heaving, and that a number of attributes not studied as yet may have considerable significance in determining behavior. The environment in which the wheat develops in the fall, both as regards soil and climate, has a profound influence on the degree of resistance to heaving. Varietal differences are largely independent of environment. The combination of resistant variety and favorable fall environment is essential to reduction of injury from heaving to a practical minimum."

Proceedings of the Association of Official Seed Analysts of North America, 1929 (*Assoc. Off. Seed Anal. North Amer. Proc., 22 (1929–30), pp. 51, pls. 2, fig. 1*).—A report of the activities of the association during 1929 and of the twenty-second annual meeting at Des Moines, Iowa, from December 31, 1929, to January 2, 1930. The following papers by station and U. S. Department of Agriculture workers are included: A Need of Our State Seed Testing Services, by F. S. Holmes (pp. 27–29) (Md.); Seed Law Enforcement, by H. R. Kraybill (pp. 30–34) (Ind.); Preliminary Report on the Viability of Hard Seed of Legumes Which Have Remained in Soil, by W. O. Whitcomb (pp. 35–38), and Impurities Commonly Found in Montana Grown Alfalfa Seed, by W. D. Hay (pp. 39–42) (both Mont.); and Preliminary Results of Soil Tests of *Agrostis* spp., by C. C. Thygeson (pp. 43–46), and A Suggested Method of Seed Testing, by A. F. Musil and M. E. Lyon (pp. 47–50) (both U. S. D. A.).

Proceedings of the Association of Official Seed Analysts of North America, 1935 (*Assoc. Off. Seed Anal. North Amer. Proc., 27 (1935), pp. 130, pls. 3, figs. 2*).—A report of the activities of the association during the year ended June 1935, and of the twenty-seventh annual meeting at St. Paul, Minn., June 27–29, 1935, inclusive. The following papers by State experiment station, U. S. Department of Agriculture, or workers from other agencies are included: Development of Seed Testing in the United States (pp. 35–39) and Germination of Fordhook Lima Beans (pp. 52–55), both by W. L. Goss, and Retarded Germination of *Hypericum* Seed Caused by Tap Water, by H. A. Borthwick (p. 124) (all Calif.); Seedling Identification (pp. 40–43) and Misbranded Seed in Interstate Commerce and Seed Analysis (pp. 108–112), both by W. A. Davidson, and The Influence of Storage Conditions on the Viability of Soybean Seed, by E. H. Toole and W. A. Davidson (pp. 125, 126) (all U. S. D. A.); An Improved Method of Testing Seeds of Kentucky Blue Grass (*Poa pratensis* L.), by E. O. Brown and R. H. Porter (pp. 44–49), Germination of Seeds of Black Locust (*Robinia pseudacacia* L.) (pp. 63–65) and Effect of Seed Borne Pathogens and of Seed Disinfectants on the Germination of Barley Seed (pp. 94–99), both by R. H. Porter, and Laboratory Detection of Smut in Oats, by G. N. Davis (p. 93) (all Iowa); Time Required for Analyzing Sweet Clover Seed Samples, by R. U. Croulcy (pp. 50, 51), Preliminary Work on Germination of *Agropyron* Caryopses, by L. M. Stahler (pp. 56–59), and The Weed Control Program, by C. P. Bull (pp. 117–120) (all Minn.); The Favorable Influence of a Moist Substratum for the Germination of Seeds (pp. 60, 61) and Some Suggestions for Testing the Viability of Hard Seeds (p. 62), both by A. L. Shuck, Further Work With Soil for Testing the Vitality of Seeds (pp. 78, 79), and Five Years' Experience With Control Fields as a Part of the Equipment of a Seed Testing Station (pp. 80, 81), both by M. T. Munn, *Ascochyta pisi viciae* in Seeds of Vetch (pp. 82–86) and Detection and Identification of Seed Borne

Parasites (pp. 87–92), both by W. F. Crosier, and The Quality of Flower Seeds Upon the New York Market, by M. T. and R. E. Munn (p. 100) (all N. Y. State); Germination of Crested Wheat Grass (*Agropyron cristatum*): Preliminary Studies, by W. D. Hay (pp. 66–70), and Interpretation of Germination Results: Transfer of Germinated Seeds From Blotters to Field Soil (pp. 73–77) and The Young Seed Analyst: His Training, Ideas, and Future (pp. 121–123), both by W. O. Whitcomb (all Mont.); The Frosted Oat Problem, by B. F. Forward (pp. 71, 72) (Alta.); Purity and Germination Tolerances Fundamentally the Same Problem, by C. W. Leggatt (pp. 101–107) (Ont.); and The Uniform Seed Label, by C. E. Buchanan (pp. 113–116) (Kans.).

HORTICULTURE

[Horticultural studies by the Florida Station] (*Florida Sta. Rpt. 1935, pp. 60, 61, 63, 74–84, 98, 99, 106–109, 140–145, 148*).—Among studies the progress of which is discussed are sources of potash for citrus, effects of various potash and nitrogen sources on the composition of citrus trees and fruits, and concentrated fertilizers for citrus, all by R. W. Ruprecht; fertilizers for pecans, by H. W. Winsor; fertilizer needs of celery, by E. R. Purvis and Ruprecht; cover crops for pecans, zinc requirements of the pecan, fertilizers for the pecan, and variety tests of pecans, all by G. H. Blackmon; propagation, planting, and fertilizer trials with tung-oil trees, effects of mulching on citrus, and effects of zinc on tung trees and citrus, by A. F. Camp; winter injury of introduced shrubs and ornamentals, and relation of nitrogen absorption to food storage and growth in the pecan, both by Camp and Blackmon; variety tests of potatoes, lettuce, and other vegetables, by F. S. Jamison; variety tests of minor fruits and ornamentals, by Camp and H. S. Wolfe; cold storage studies with oranges and grapefruit, by Camp and A. L. Stahl; and citrus maturity as indicated by sugar and acid, by Stahl.

Studies carried on at the Citrus Experiment Station included propagation experiments with citrus, by J. H. Jefferies. At the Everglades Experiment Station there were conducted studies of varieties of fruits, tung trees, and ornamentals, by R. V. Allison, G. R. Townsend, and R. N. Lobdell, and fertilizer tests with truck crops, by Allison, A. Daane, R. E. Robertson, and F. D. Stevens. Studies at the Subtropical Experiment Station dealt with tests of minor fruits and ornamentals as to hardiness, and fertilizer experiments with mangoes, both by Camp and Wolfe; cultural studies with avocados, and rootstocks for Persian limes, both by Wolfe; and fertilizers for tomatoes and tomato variety tests, both by Wolfe and W. M. Fifield.

[Horticultural studies by the Idaho Station], H. P. Magnuson and L. Verner (*Idaho Sta. Bul. 220 (1936), pp. 9, 36, 37–39, fig. 1*).—There are discussed various activities, including the removal of residues from apples, the breeding of apples, the fertilization of apple, prune, and cherry trees, testing of new fruits, factors involved in the cracking of sweet cherries, and the low-cost production of fruit juice concentrates from surplus and cull fruits.

[Horticultural studies by the Montana Station] (*Montana Sta. Rpt. 1934, pp. 35, 36, 56–59, 64, 65*).—Among projects discussed are those relating to fertilizer and cover crop experiments with the apple and cherry, the testing of raspberry varieties, the culture of tomatoes, control of strawberry yellows, testing of strawberry varieties, testing of broadleaf and conifer species for shelterbelts, and the testing of various ornamental shrub and iris varieties.

[Horticultural studies by the New Jersey Stations] (*New Jersey Stas. Rpt. 1935, pp. 23, 24, 46–57, 58–62, fig. 1*).—Among experiments the progress of which is reviewed are fertilizer, cultural, and propagation studies with the

blueberry; fertilizer and breeding studies with the cranberry; control of cranberry and blueberry pests; winter injury to peach; peach breeding; peach propagation; rootstocks for peaches; apple breeding; growth status of apple trees; performance of Delicious apple spurs of different sizes; breeding of strawberries; testing of varieties of small fruits; winter injury to grapes and other small fruits; culture of raspberries; effect of soil reaction on the strawberry; tomato breeding; asparagus breeding; variety testing of tomatoes, sweet corn, and peppers; effects of high nitrogen supply and temperature on the setting of string and lima beans; response of vegetables growing in highly acid soils or in soils of low available calcium to application of soluble calcium salts; the relation of salt concentration in the nutrient solution to sterility of greenhouse plants, such as the tomato; sand culture of roses, poinsettias, and sweet peas; effects of temperature on growth, anatomy, and metabolism of apple and peach roots; the metabolism and bud abscission of the sweet pea; and a new washing method for removing spray residue.

[Horticulture at the Ohio Experiment Station], J. H. GOURLEY ET AL. (*Ohio Sta. Spec. Circ. 48 (1936), pp. 1–59, figs. 13*).—Information is presented on recent experimental activities in the fields of pomology, ornamental horticulture, and olericulture.

[Horticultural research papers] (*Assoc. South. Agr. Workers Proc., 35 (1934), pp. 309, 310, 312, 313, 315–317, 321–326; 36 (1935), pp. 476, 477, 555, 556, 559–564, 567–569*).—The following subjects were presented at the thirty-fifth and thirty-sixth annual conventions of the Association of Southern Agricultural Workers: Propagable Vegetative Variations in Relation to Crop Improvement, by B. D. Drain (pp. 309, 310); The Germination of Strawberry Seeds and the Technic of Handling the Seedlings, by E. M. Henry (pp. 312, 313); A Physiological Study of Fruit Development in the Pecan (*Hicoria pecan*), by C. L. Smith and C. J. B. Thor (pp. 315, 316); Further Studies on Periods of Receptivity and Pollen Viability in the Pecan, by C. L. Smith and L. D. Romberg (pp. 316, 317); The Influence of Planting Depth on the Shape of the Scarlet Globe Radish, by J. B. Edmonds (pp. 321–323); Yield Relationships on Terminal Growths in York Imperial Apples, by F. W. HofMann (pp. 323–325); Physiological and Chemical Studies of Grapes, by F. B. Cross and J. E. Webster (pp. 325, 326); The Effect of Copper Sulfate on the Yield and Quality of Oranges, by W. E. Stokes (pp. 476, 477); Uniformity Trials with Asparagus and Peach Plots, by L. E. Scott (pp. 555, 556); Newer Strains and Varieties of Vegetables Recently Tested in the Southern States, by F. S. Andrews (pp. 559–561); Some Factors in Peach Tree Longevity in Some Sections of Georgia, by W. D. Armstrong (pp. 561, 562); The Effect of Fertilizers on Elberta Peach Fruits, by M. M. Murphy, Jr. (pp. 562, 563); Abstract of Fall Fertilization of Peach Trees, by C. F. Williams (p. 564); Some Relations of Male Vines to the Bearing of Muscadine Vines, by W. D. Armstrong (p. 567); and Disbudding in the Nursery Row as a Possible Means of Improving the Frame Work of Apple Trees, by C. B. Wiggans (pp. 568, 569).

Fruits and vegetables in ripening and blanching produce ethylene, R. C. NELSON and R. B. HARVEY (*Minn. Hort., 63 (1935), No. 6, p. 105; abs. in Minnesota Sta. Rpt. 1935, p. 47*).—As indicated by the peculiar effect of ethylene in causing the drooping of tomato leaves, the gases given off by Golden Self-Blanching celery were found to contain ethylene. On the other hand the green Winter Queen celery not in a blanching condition did not give off the gas. Since ethylene production is a natural phenomenon associated with various fruits and vegetables, the authors believe that its use in hastening maturity cannot be considered harmful.

Shrivelling of fruits and vegetables, R. B. HARVEY and R. H. LANDON (*Market Growers Jour., 56 (1935), No. 7, pp. 155, 158, figs. 2*).—In this further contribution from the Minnesota Experiment Station to the general subject (E. S. R., 74, p. 199), the authors present additional information on tomatoes and also some data on squashes, apples, and melons. Coating Buttercup squashes with water wax was particularly effective in cutting down water losses in storage. Water wax required brushing to produce a polished surface. Another type of material containing shellac became slightly sticky under high humidities and was not as desirable. No evidence of smothering was shown by apples or squashes treated with either material. In the case of muskmelons there was indicated an accumulation of moisture in the outer part of the rind under the wax, thus favoring the growth of fungi.

Diseases and insect pests of cabbage and related plants: Identification and control, L. H. SHROPSHIRE and K. J. KADOW (*Illinois Sta. Circ. 454 (1936), pp. 47, figs. 21*).—This is a presentation of general information.

Experiments with rapid chemical soil tests for vegetable crops, J. B. HESTER (*Amer. Soc. Agron., Com. Fert. Proc., 1 (1935), pp. 78–85, figs. 3*).—The results are presented of experiments at the Virginia Truck Experiment Station upon various rapid tests for pH, replaceable calcium, organic matter, phosphorus, magnesium, and potash.

Acid-neutral fertilizers in vegetable crop production in eastern Virginia, J. B. HESTER and H. H. ZIMMERLEY (*Amer. Soc. Agron., Com. Fert. Proc., 1 (1935), pp. 38–43, pl. 1, figs. 4*).—Studies by the Virginia Truck Experiment Station upon the use of dolomitic limestone of different degrees of fineness added to the fertilizer mixture as compared with the use of neutral salts and commercial fertilizers based down with dolomitic limestone for crops growing on a Sassafras sandy loam of pH 6.2 indicated that the degree of fineness of limestone influences greatly the rapidity with which the calcium neutralizes the acidity of the soil. Rock phosphate was not effective in neutralizing the acidity developed from the sulfate of ammonia. Dolomitic limestone of the same fineness but of different origin had different degrees of activity in the soil.

Vegetable variety tests at the Scottsbluff Substation, L. HARRIS (*Nebraska Sta. Bul. 300 (1936), pp. 27, figs. 2*).—In addition to presenting the results of variety tests extending over the 5 yr. 1931–35 and including most of the important species, information is presented on culture, irrigation, desirable rotations, and the arrangement of vegetables in the home garden.

Floral biology and morphology of the eggplant, M. V. MAGTANG (*Philippine Agr., 25 (1936), No. 1, pp. 30–53, pls. 5, fig. 1*).—In this discussion of the development of the flower, gametophytes, fruit, and seed the author points out that eggplants require pollination to set fruit and that plants are both self- and cross-fertile.

Fertilizing onions on muck soils, J. E. KNOTT ([*New York*] *Cornell Sta. Bul. 650 (1936), pp. 20, fig. 1*).—Fertilizer experiments carried on over a 5-yr. period on three widely separated muck areas which had been under cultivation for different periods showed that the duration of the period under culture is the most important consideration in developing fertilizer practices.

On one area cultivated only 3 yr. prior to the experiment the use of nitrogen actually decreased the yield as compared with no nitrogen, the odds being 30:1 that no nitrogen was better than 70 lb. The maximum application of phosphoric acid (192 lb.) was needed for maximum yields, and during the first 4 yr. 195 lb. of potash per acre gave significant increases over lesser quantities.

On a muck tilled for 20 yr. all the nitrogen treatments gave increased yields. Plats receiving no phosphoric acid yielded better than those receiving 64 or

192 lb. per acre, and the phosphorus had no visible effect on the ripening of the onions.

On muck tilled for 30 yr. but not fertilized as liberally or consistently as the other old mucks nitrogen in all amounts proved effective, and phosphoric acid both in 64- and 128-lb. applications increased yields. Potash, however, failed to give any significant increases.

On a muck cultivated for 56 yr. none of the fertilizer treatments had any significant effect, but, since the initial reaction of the soil was below pH 5.2, the author suggests that the low pH value may have interfered with fertilizer effects.

In general conclusion the author points out that fertilizer plat work with muck crops is difficult, due to previous treatments and to differences in drainage, prevalence of insects and disease, and the stand. He presents practical recommendations for fertilizing mucks of different cultural ages.

The anatomy and histology of the transition region of Tragopogon porrifolius, L. HAVIS (*Ohio State Univ., Abs. Doctors' Diss., No. 17 (1935), pp. 229–234*).—Herein are presented in abstract form the results of a study with salsify (E. S. R., 74, p. 759).

Effects of light on carotenoid formation in tomato fruits, O. SMITH ([*New York*] *Cornell Sta. Mem. 187 (1936), pp. 26, pl. 1, figs. 30*).—Using largely the Bonny Best variety, the author found that greenhouse-grown tomato fruits did not contain as large a quantity of carotenoid pigments as did fruits produced out of doors. When early growth took place under the same light conditions the carotenoid content of both the skin and flesh of tomato fruits ripened in light was higher than that of fruits ripened in the dark. To secure the maximum carotenoid content the fruits should be ripened on the vine in full exposure to light. With reference to the quality of light it was observed that wave lengths approximating 5,400 to 5,800 a. u. were not conducive to the maximum production of carotenoid pigments, but that some of the longer and shorter wave lengths were favorable. There was some indication of a possible transfer of carotenoids or carotenoid-producing substances from the plant to the fruit.

The results of quantitative determinations of carotenoids in fruits grown under different light conditions, as well as of microscopic studies of pigments, indicated that protection from intense light favors lycopene formation. The presence of lycopene in mature fruits which had been grown in complete darkness is believed to indicate that lycopene cannot be an oxidation product of chlorophyll as has been suggested by other workers. Lycopene was not found in plastids and occurred only in crystalline or semicrystalline form. Carotene was found in granular form both inside the plastids and after their decomposition, and its was also found in crystalline and globular forms. Plastids of mature green fruits were smaller and less numerous in tomatoes grown in the absence of light than those grown in normal light. The color of Bonny Best fruits developed in normal light is believed due to the lycopene in the skin and flesh, the carotene in the skin and flesh, and to an unidentified pigment in the walls of the epidermal cells.

[Plant improvement activities of the South Dakota Station], N. E. HANSEN (*South Dakota Sta. Rpt. 1935, pp. 34, 35*).—Brief mention is made of crossing experiments with apricots and apples.

Orchard cover crops, O. M. MORRIS (*Wash. State. Hort. Assoc. Proc., 31 (1935), pp. 65–67*).—Pointing out that neither alfalfa nor sweetclover have become perennial cover crops in Washington orchards because of light seed production under orchard environments and because of disking and other cultural operations, the author suggests the need in many orchards of returning

to clean tillage for a period of from 1 to 3 yr., relocating the irrigation ditches to secure a wider distribution of apple roots, and finally reseeding to establish good cover crops.

The apples of England, H. V. TAYLOR (*London: Crosby Lockwood & Son, 1936, pp. 266, pls. 9*).—Devoted principally to the description of varieties grown in England, this monograph discusses the characteristics that distinguish varieties, presents a historical account of the development of British apples, gives information on their uses for dessert, culinary, and cider-making purposes, and includes other related facts.

Fertilizer needs of red raspberries, A. E. STENE (*Better Crops with Plant Food, 20 (1936), No. 9, pp. 12–14, 39–41, figs. 2*).—At the Rhode Island Experiment Station it was found that on two different soils of fair fertility red raspberries showed a very definite response to potassium, with nitrogen second and phosphoric acid third in order. Under conditions in which a complete fertilizer produced an average yield of 2,845 qt. per acre over a 3-yr. period, N–K produced 2,600 qt., P–K 1,816, and N–P 1,294 qt.

Results with fertilizers on the red raspberry, W. J. STRONG (*Sci. Agr., 16 (1936), No. 8, pp. 424–439, pl. 1, figs. 3; Fr. abs., p. 439*).—Records taken at the Ontario Horticultural Experiment Station, Vineland, over a period of 3 yr. on the yields of Viking red raspberries fertilized with nitrate of soda, superphosphate, and sulfate of potash showed definitely beneficial effects from the nitrogen and potash materials but nonsignificant results from phosphoric acid. At the beginning of the experiment the top 1 to 8 in. of soil had a pH of 6.5 and was found well supplied with available phosphorus but rather low in replaceable potassium. No evidence was seen of interactions between nitrate of soda, superphosphate, and sulfate of potash in the various combinations.

Nutrition of blueberry (Vaccinium corymbosum L.) in sand cultures, O. A. DONEHLEET and J. W. SHIVE (*Soil Sci., 41 (1936), No. 5, pp. 341–350*).—Using root cuttings of the Rubel blueberry grown in sand cultures supplied with different nutrient solutions by the continuous drip method, the authors found that the most favorable solutions were those low in phosphate and high in nitrogen. The results were thus in close agreement with earlier information obtained in the field (E. S. R., 70, p. 780). The superiority of nitrate nitrogen over ammonium nitrogen is explained on the basis of a pH of about 4.5 of the nutrient solutions. Many of the plants made excellent growth and yielded crops comparable with those secured in the field. The lack of boron and manganese resulted in definite deficiency symptoms in relatively short periods.

Effect of nitrogen fertilizers on strawberry production, R. A. LINEBERRY and H. B. MANN (*Jour. Elisha Mitchell Sci. Soc., 51 (1935), No. 2, pp. 209, 210*).—Source of nitrogen trials indicated that the type of soil to which materials are applied is a potent factor in results. Strawberries produced on plats receiving a mixture of organic and inorganic nitrogen were firmer than those from plats receiving inorganic nitrogen alone. The use of quickly soluble inorganic nitrogen resulted in low viability of plants during the summer. As regards effects on earliness and shipping quality, spring applications of nitrate of soda or ammonium sulfate in addition to complete fertilizer were injurious but in moderate quantities increased total yields.

Strawberry culture in Illinois, A. S. COLBY (*Illinois Sta. Circ. 453 (1936), pp. 52, figs. 28*).—This is a presentation of general information relating to selection of soils, choice of varieties, establishment of plantations, general management, irrigation during drought, harvesting, marketing, control of pests, etc.

Field and storage studies on changes in the composition of the rind of the Marsh grapefruit in California, E. M. HARVEY and G. L. RYGG (*Jour. Agr. Res.* [*U. S.*], *52 (1936), No. 10, pp. 747–787, figs. 14*).—Utilizing grapefruits produced in different districts of California, it was noted that environment plays an important role in the changes taking place in the rind as the fruits develop on the tree and subsequent storage. Water content showed a slight seasonal upward trend in all instances. The flavedo-albedo ratio was also affected by environment, with certain exceptions at the close of the season. Soluble solids increased throughout the growth period in all localities. Total sugar increased in two districts, Corona and Fontana, until July 23, whereas at Oasis total sugar tended to increase throughout the season. Hydrolyzable polysaccharides showed a steady relative decline throughout the season at all localities. With certain local variations naringin decreased in general through the season in all localities. The difference in composition of the stem and blossom end portions of the rind were less marked at Oasis than at other points.

On the whole the differences between flavedo and albedo tissues were smaller than in the orange but here again were influenced by environment. As to the effects of storage temperatures fruit from all three localities pitted and spotted more severely at 42° F. and least at 52°. Picking season was also a factor in spotting. The permeability of rinds to their own soluble substances increased as the storage temperature was lowered. When solutions of naringin and its derivative naringenin were injected into the albedo, the latter was approximately 1,000 times more toxic to the tissues than was naringin, and, since the spots developing in the rind after injection with naringenin resembled those in ordinary stored grapefruit, the association of this chemical with ordinary storage spotting is surmised. The temperatures that gave the greatest amount of common storage spotting were the most favorable to naringenin injury. There were noted differences between individual fruits in their susceptibility to naringenin. The results of various chemical analyses of the rinds are presented in considerable detail.

Rootstocks for the Bearss lime in California.—A progress report, R. W. HODGSON, E. R. EGGERS, and S. H. CAMERON (*Calif. Citrogr., 21 (1936), No. 8, p. 280, fig. 1*).—Observations on 7-year-old Bearss limes budded on sweet and sour orange, rough lemon, grapefruit, and trifoliate orange rootstocks showed the largest trees to be on grapefruit, with yields almost equal on grapefruit and rough lemon. Trifoliate orange markedly dwarfed the limes, and the sour orange had a similar but less potent effect. The form of the bud unions was similar in all cases, namely, an overgrowth on the part of the scion. The fruits were apparently similar except for a tendency to be smaller on the trifoliate roots. Own-rooted lime trees were larger than those on either trifoliate or sour orange.

Phosphorus relations of lemon cuttings grown in solution cultures, A. R. C. HAAS (*Bot. Gaz., 97 (1936), No. 4, pp. 794–807, figs. 6*).—Rooted Lisbon lemon cuttings grown by the California Experiment Station at Riverside in an unaerated culture solution lacking phosphate were supplied with different concentrations of phosphate added as potassium acid phosphate. Cuttings grown in solutions containing from 0 to 0.2 p. p. m showed phosphorus deficiencies regardless of the frequency of change of the solutions. Slight symptoms of deficiency occurred at 1 p. p. m. but none at 2 p. p. m. Root length was in inverse ratio to phosphate concentration. Concentrations as high as 105 p. p. m. were not harmful when vigorous aeration was provided. As contrasted to the orchard, where a decrease was noted as the leaves matured,

the percentages of phosphorus in the mature original leaves of the cuttings increased with increasing phosphate concentration. A relation was apparent also between the percentage of phosphorus in the culture solution and the percentages of sucrose in the mature leaves. Phosphate-deficient leaves had a greater acidity than healthy leaves. Percentages of total ash, calcium, potash, and total and nitrate nitrogen in the new mature leaves were greatest at the lowest concentrations of phosphate. In the absence of sufficient phosphorus the absorbed nitrates remained largely unchanged, and thus trees with abundant nitrate may be essentially nitrogen starved.

Report on a girdling test with Washington Navel orange trees, A. D. SHAMEL and C. S. POMEROY (*Calif. Citrogr., 21 (1936), No. 9, pp. 320, 343, fig. 1*).—As a result of a single girdling Washington Navel orange trees showed consistent increases in production, whereas those girdled for from two to four consecutive years produced about the same as the nongirdled trees. After 7 or 8 successive years of girdling a significant loss in production occurred, and vigor of the trees was noticeably impaired. The grade and size of the fruits were about the same from the girdled and the nongirdled trees. As indicated by the cross section of the trunk, girdling for a period of 6 successive years or more resulted in diminished growth.

Physiological changes in the rind of California oranges during growth and storage, E. M. HARVEY and G. L. RIGG (*Jour. Agr. Res. [U. S.], 52 (1936), No. 10, pp. 723–746, figs. 5*).—Seeking an explanation of the causes of certain rind spotting and pitting diseases that occur during transportation and storage, the authors investigated the changes taking place normally in the rinds of Valencia and Washington Navel oranges on the tree and during storage at different temperatures. As was expected, there were important differences between the two varieties because of their different characteristics and ripening seasons, and, although the results did not contribute much information on pitting and spotting, they are considered of significance.

Designating the outer rind as flavedo and the inner rind as albedo, it was observed that in Valencia the flavedo always weighed more than the albedo, whereas in the Washington Navel orange the ratio averaged more than unity. In the Valencia the flavedo contained a higher percentage of invert sugar, total sugar, soluble solids, and nitrogen than the albedo. In the Washington Navel the flavedo was higher in percentage of reducing sugar, invert sugar, and soluble solids. As the season progressed there was an increased water content in the rinds of Valencia oranges, with the reverse true in the Washington Navel orange. In Valencia soluble solids varied inversely with mean temperature. In the Washington Navel there was a general relative increase throughout the season. In Valencia total sugar remained practically constant but in the Washington Navel increased throughout the season. In Valencia hydrolyzable polysaccharides varied with the mean temperature, while in the Washington Navel orange they decreased as the season advanced. Hesperidin, determined only in the Washington Navel orange, decreased steadily during the season. H-ion concentration made a small but definite decrease during the season. Well-defined differences were found in the percentage composition of the stem end and blossom end of both varieties.

In storage experiments at 33° and 53° F. for 7 weeks the rind from the stem end of Valencias lost soluble solids twice as rapidly as did the blossom end. Soluble solids decreased more rapidly at 53° than at 33°, and the rinds at 33° had a higher H-ion concentration. With Washington Navels stored at 52°, 42°, and 32° there was noted increased acidity in all portions of the rind at all three temperatures, but greatest at 52°. Hesperidin increased at all three temperatures.

Late-picked Washington Navel oranges were most susceptible to brown stain, and 32° increased this susceptibility. Pitting and spotting could not be associated definitely with maturity or storage temperature.

Seedling production in Carya ovata (Mill.) K. Koch, Juglans cinerea L., and Juglans nigra L., L. V. BARTON (*Contrib. Boyce Thompson Inst., 8 (1936), No. 1, pp. 1–5, fig. 1*).—Observations on the germination of seeds of the above three species collected before frost and planted in flats in a mixture of peat, sand, and soil showed that pretreatment at low temperatures for from 2 to 4 mo. in a moist medium is necessary for seedling production in the black walnut and the butternut. Seedling production in the hickory was increased by pretreatment in moist soil for from 1 to 5 mo. at 3° or 10° C., but some seedlings were produced without this pretreatment. A period of high temperature preceding low temperature treatment had no effect on this species. Good results with all three species were secured by fall planting when the seedbeds were protected by mulch or boards from alternate freezing and thawing.

Effects of thinning the trees in a pecan orchard, M. B. HARDY, N. H. LOOMIS, and H. LUTZ (*Southeast. Pecan Growers Assoc. Proc., 30 (1936), pp. 4–9*).—In a block of Stuart trees planted 20 to the acre in 1908, a reduction in the number of trees to 10 in 1932 was compared with (1) heavy fertilization with ammonium sulfate, (2) heavy pruning, and (3) moderate fertilization (control). No cover crops were grown subsequent to 1932, and only one cultivation was given each year just prior to harvest. For the 4 yr. 1932–35 the average gains in cross sectional area of the trunk were 4.13, 4.61, 3.51, and 6.1 sq. in. for the control, heavily fertilized, heavily pruned, and tree-removal plats. The average yield in pounds of nuts per tree for the 3 yr. 1933–35 were 6.06, 10.42, 0.57, and 8.3, respectively. As indicated by these averages the yields per acre were not sufficient to offset the reduction in the number of trees. Grading showed that the heavily pruned and reduced-tree plats had produced the larger and better-filled nuts. Unfavorable moisture conditions during the period of the experiment are believed to have decreased the favorable responses from treatments.

Effects of fertilizers on the yield of pecan trees, G. H. BLACKMON (*Southeast. Pecan Growers Assoc. Proc., 30 (1936), pp. 19–25*).—A study by the Florida Experiment Station of records taken on fertilizer experiments with Curtis, Kennedy, Moneymaker, Moore, Stuart, and Success pecans showed with one exception yield increments in all the fertilized trees of each variety regardless of the nature of the treatment. The single failure was due to the presence of rosette disease. Moore, the most productive variety of the six, was a consistent annual bearer. The value of well-balanced fertilizers applied annually was indicated, with some suggestion that nitrogenous materials applied during July are beneficial in maintaining annual production.

Effect of various nitrogen fertilizers on nitrates in the soil and on pecan tree growth on Greenville sandy loam, R. D. LEWIS and E. D. FOWLER (*Southeast. Pecan Growers Assoc. Proc., 30 (1936), pp. 34–46*).—Schley trees 10 yr. old in 1932 and located on a Greenville sandy loam were uniformly treated with nitrogen, phosphorus, and potassium, except that the sources of nitrogen were different. Trees receiving nitrogen from one-third ammonium sulfate, one-third cottonseed meal, and one-third sodium nitrate made the largest increase in circumference each year, and the soil contained the highest average amount of nitrates with the most uniform distribution throughout the year. Nitrogen in the form of calcium nitrate, sodium nitrate, cyanamide, and Calurea tended to decrease the soil acidity, whereas ammonium sulfate and Ammo-Phos produced additional acidity.

A cover crop program for Florida pecan orchards, G. H. BLACKMON and R. M. BARNETTE (*Florida Sta. Bul. 297 (1936), pp. 44, figs. 20*).—Suggesting that many plantings have been made in Florida on soils different from those in the regions where the pecan is native and that one of the major problems is to maintain sufficient growth in the older trees, the authors discuss the results of cover crop experiments begun in 1927 in an orchard of Frotscher and Stuart varieties in which the trees were low in vigor and production was at a minimum. Beneficial results both in growth and yield were obtained with leguminous cover crops, and, while the response was greater where complete fertilizers were used with the cover crops, there were no significant differences until the cover crops had been grown for 4 yr. The combination of hairy vetch and *Crotalaria spectabilis* produced the greatest amount of green material containing the most nitrogen, followed closely by an Austrian pea and *Crotalaria* combination. Oats in winter and *Crotalaria* in summer failed to increase production. The Frotscher variety produced much heavier crops than Stuart and consequently gave more profitable returns for the treatments. There were no significant differences in the size of nuts and kernel percentages on the several plats.

An examination of the surface soil showed an increased nitrogen content where cover crops were planted and a decrease when only the natural growth of native nonlegumes was present. Organic matter content increased slightly on two of the cover crop plats. In conclusion suggestions are presented for the planting of both winter and summer legumes with recommendation for checking the summer cover crop by disking during dry periods. A broadcast application of from 200 to 300 lb. of superphosphate and from 50 to 60 lb. of sulfate of potash is suggested before seeding the winter legumes, supplemented in June and July with from 5 to 20 lb. of ammonium sulfate or nitrate of soda per tree, depending on their size.

Roses, E. R. HONEYWELL (*Indiana Sta. Circ. 216 (1936), pp. 16, figs. 13*).—General information is presented on species, varieties, propagation, pruning, cultural requirements, winter protection, and the control of various insect and fungus pests.

FORESTRY

The Cloquet Forest: A demonstration of practical forestry in northern Minnesota, T. S. HANSEN, J. H. ALLISON, R. M. BROWN, E. G. CHEYNEY, and H. SCHMITZ (*Minnesota Sta. Tech. Bul. 112 (1936), pp. 84, figs. 49*).—Beginning with an account of the location, environment, and establishment of the forest, the authors discuss the present composition of the forest flora, management plans under which the forest is operated, growth rates and production, and possibilities of sustained yield, and present various area, stock, and growth tables based on measurements taken in the forest. An appendix sets forth the silvical characteristics of the important species, namely, jack, Norway, and white pines, aspen, birch, balsam fir, black spruce, tamarack, and white cedar.

Ohio Forest News, [July 1936] (*Ohio Forest News [Ohio Sta.], No. 28 (1936), pp. 8, figs. 2*).—General notes are presented with reference to State forests, Dutch elm disease, conservation matters, reforestation, etc.

Germination of Populus grandidentata and P. tremuloides, with particular reference to oxygen consumption, M. E. FAUST (*Bot. Gaz., 97 (1936), No. 4, pp. 808–821, fig. 1*).—Herein are presented the results of storage, germination, and respiration studies with seeds of two species of poplar collected near Syracuse, N. Y. Among the findings were that in any single species large seeds germinate more readily and retain their viability longer than do small seeds, that a pH of from 7 to 8.5 gives the highest germination, that a

constant storage temperature approximating 5° C. favors long viability, that the largest percentage of germination occurs at 29° and 32°, that oxygen consumption is high when seeds are viable and contain much water, and that seeds of both species contain fats and proteins.

Methods and significance of pollen analysis [trans. title], H. GAMMA (*Schweiz. Ztschr. Forstw., 87 (1936), No. 6, pp. 180–186, figs. 2*).—With the aid of diagrams and descriptive matter the distinguishing characteristics of the fossil pollens of different forest species are pointed out. Of the various pollens found in peat those of *Abies, Pinus, Picea, Betula, Corylus, Alnus, Fagus, Carpinus, Quercus, Ulmus, Tilia,* and *Salix* are said to be most commonly found. The usefulness of pollen determinations for following the migration of trees since the ice age and in showing the composition of the prehistoric forests is indicated.

Variations in naval-stores yields associated with weather and specific days between chippings, V. L. HARPER and L. WYMAN (*U. S. Dept. Agr., Tech. Bul. 510 (1936), pp. 35, figs. 16*).—A study of gum yield records taken by the Southern Forest Experiment Station in forests of northern Florida from 1926–32, inclusive, and correlated with existing weather data showed that average air temperature, soil temperature, and evaporation have a large influence on gum flow in the first 24 hr. after chipping, accounting for approximately 90 percent of the variation in yield. Air temperature was by far the most influential factor of the three. There was no indication that rain had any definite effect on the yield of gum. With both species, longleaf and slash pines, the net effect of weather conditions on gum yield increased with the increasing interval following chipping. The two species had different capacities for sustained flow of gum; for example, with an air temperature averaging about 82° F. longleaf pines yielded 90 percent of their weekly total during the first 48 hr., whereas slash pines required about 96 hr. to reach the same percentage. At 52° both pines required 6 days to yield 90 percent of their weekly total. The rate of gum flow for slash pines was observed to reach a daily maximum at 9 a. m., the rapidity in rise of rate being directly associated with the rate of air temperature rise. Yield increases during the day were associated to a slight degree only with stem contractions, but in the few cases in which the stem expanded there was a marked decline in yield. As weekly chipping was continued there was a downward trend in production amounting to approximately 20 percent over a year. The optimum chipping interval was in general longer for the slash than for the longleaf pine.

Logging—transportation, N. C. BROWN (*New York: John Wiley & Sons; London: Chapman & Hall, 1936, pp. XV+327, figs. 167*).—This is a treatise on the principles and practice of log transportation in the United States and Canada.

DISEASES OF PLANTS

The Plant Disease Reporter, June 1, June 15, and July 1, 1936 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 20 (1936), Nos. 10, pp. 154–175, figs. 2; 11, pp. 176–186, figs. 2; 12, pp. 187–199*).—Among other items of current interest, these issues contain notes on the following:

No. 10.—A list of plants attacked by the leaf nematode (*Aphelenchoides fragariae*) (including 179 hosts, and 5 in the literature omitted because of probable errors), by L. Crossman and J. R. Christie; the relation of ear rot prevalence in Illinois cornfields to ear coverage by husks, by G. H. Boewe; reports on tobacco seedbed diseases in Maryland and Florida, by E. A. Walker and R. R. Kincaid, respectively; first blister rust (*Cronartium ribicola*) found

on sugar pine (*Pinus lambertiana*), by J. L. Bedwell; occurrence of rusts on cedars in Maine (including *Gymnosporangium juniperi-virginianae*, *G. globosum*, and *G. nidus-avis* on *Juniperus virginiana*, *G. clavipes* and *G. clavariaeforme* on *J. communis depressa*, *G. juvenescens* on *J. horizontalis*, and *G. ellisii* and *G. biseptatum* on *Chamaecyparis thyoides*), by *F. H. Steinmetz;* and *Volutella pachysandrae* blight on *Pachysandra* in New Jersey, by G. Westcott.

No. 11.—A destructive disease of the mimosa tree (*Albizzia julibrissin*) in the Carolinas (from which a *Fusarium* of the *oxysporum* group of the section *Elegans* was regularly isolated), by G. H. Hepting; sugarcane diseases in Puerto Rico, by J. H. Jensen; reports on apple scab (chiefly phenological data) in Massachusetts (by O. C. Boyd), in New York (by J. G. Goodrich), and in Wisconsin (by R. E. Vaughan); reports of blight on apple (chiefly phenological data) in Massachusetts (by O. C. Boyd), in New York, and in Wisconsin (by R. E. Vaughan); rust on apple in Massachusetts (by O. C. Boyd) and New York (by various observers) (chiefly phenological data); and severe damage to strawberries in Massachusetts from winter injury and dwarf (*Aphelenchoides fragariae*), by O. C. Boyd.

No. 12.—Downy mildew (*Peronospora tabacina*) of tobacco appears in Kentucky, and observations on diseases in tobacco beds in western Kentucky, both by E. M. Johnson; tobacco seedbed survey in Wisconsin, 1936 (chiefly on diseases), by J. Johnson; diseases of cabbage and beans in Copiah County, Miss., by P. R. Miller; low temperature injury of apple blossoms and scarcity of blight (*Bacillus amylovorus* [=*Erwinia amylovora*]) in Arkansas in 1936, by H. R. Rosen; crown rot (*Sclerotium delphinii*) of ornamentals in New Jersey, by C. Westcott; a mosaic disease of peach in Kentucky, by W. D. Valleau; and mottling or breaking in dames rocket (*Hesperis matronalis*) in Oregon, by F. P. McWhorter.

[Phytopathological studies by the Florida Station] (*Florida Sta. Rpt. 1935, pp. 42, 45, 62, 64, 65, 85–94 96–98 99, 100, 117, 118, 123–126, 129, 130, 132, 134, figs. 4*).—Progress reports are given of studies on field corn (analyses for nitrogen fractions) with "white bud", and corn not so affected due to applications of zinc, by W. A. Leukel and J. P. Camp; "chlorosis" in corn and other field crop plants and the effects of zinc sulfate applications, by R. M. Barnette and Camp; chlorosis in corn and other field crop plants and its control by various treatments, by Barnette; bronzing or copper leaf of citrus and the effects of lime treatments, by C. E. Bell and R. W. Ruprecht; starving out root knot nematodes by the use of *Crotalaria spectabilis*, by J. R. Watson; treatments for new outbreaks of citrus gummosis and the relations of various fungi to the malady; downy mildew of cucurbits, by G. F. Weber; certain diseases of strawberries of importance in Florida (including the relation of soil reaction to crop failure or poor condition, and "black root" in relation to soil reaction and various micro-organisms), by A. N. Brooks and R. E. Nolen; disease control in potatoes (including *Sclerotinia sclerotiorum* rot, seed-piece decay due to *Fusarium oxysporum* or a closely related form, and *Rhizoctonia* infection), and investigation and control of brown rot of potatoes and closely related plants caused by *Bacterium solanacearum* [=*Phytomonas solanacearum*] by inoculated sulfur and lime treatments, both by A. H. Eddins; investigation and control of a disease of corn caused by *Physoderma zeae-maydis*, and ear rot diseases of corn caused by *Diplodia* spp., with collections from over 21 other hosts, both by R. K. Voorhees; investigation and control of *F. nivcum* wilt and other fungus diseases of watermelons, by M. N. Walker; the so-called rust of *Asparagus plumosus*, by W. B. Shippy; control of *F. lycopersici* wilt of tomatoes (including breeding and selection of resistant varieties), by Weber and D. G. A.

Kelbert; *Clitocybe tabescens* mushroom root rot of citrus and other woody plants, by A. S. Rhoads; control of black spot (*Phoma destructiva*) of tomatoes in Florida and in transit, by W. B. Tisdale and S. Hawkins; *Colletotrichum fragariae* wilt or crown rot of strawberries, by Brooks; decays of citrus fruits in storage, including comparisons of various fungicides, by Tisdale and E. West; the spraying requirements necessary to control grape diseases in Florida, by K. W. Loucks; a bark disease of Tahiti lime trees, including isolations (*Phomopsis* in the majority of cases from cold-injured young trees), by Tisdale; *Sclerotium rolfsii* in Florida.—Its host relations and factors influencing its pathogenicity (including three new hosts), by West; rose diseases in Florida and their control (including control of black spot, the relation of sunlight to growth and deadwood, and nematode root knot), by Shippy; fruit rots (black rot and bitter rot) of grapes, by Loucks; melanose of citrus and its control, by G. D. Ruehle and W. A. Kuntz; die-back of citrus, including analyses of leaves, stems, and fruits of normal and abnormal trees with and without copper sulfate treatments, by B. R. Fudge; citrus scab and its control, by Ruehle; stem-end rot of citrus caused by *P. citri*, by Kuntz; sugarcane diseases (eyespot, red stalk rot, and mosaic), by B. A. Bourne; potato seed-piece decay, bacterial blights of green beans (*Phytomonas* spp.), root knot of beans and the relation of nematodes (*Heterodera marioni* and *Acrobeles complexus*), blight of lima beans, damping-off of vegetable seedlings, early blight of celery, spraying and dusting of Bountiful beans, spraying of lima beans, potatoes, and tomatoes, amaryllis mosaic, zinc deficiency disease of beans, and U. S. D. A. potato seedling tests, by G. R. Townsend; and field and laboratory studies of tobacco diseases (downy mildew, mosaic, and blackshank, including the development of strains of cigar-wrapper tobacco resistant to the last), by L. O. Gratz and R. R. Kincaid.

[Phytopathological studies by the Idaho Station] (*Idaho Sta. Bul. 220 (1936), pp. 7, 8, 39–43, figs. 3*).—Progress reports are given on observations and studies on the amelioration of chlorosis of apple trees by injection of iron salts alone or with zinc sulfate; the development of beans resistant to mosaic, curly top, and root rot; the incidence of and losses by curly top in vegetables and flowering ornamentals; fungus root rots of peas; mosaic of peas, red clover, and alsike clover; potato virus diseases; potato seed treatment for *Rhizoctonia*; seed treatment for diseases of cereals, including wheat bunt; losses by and development of varieties resistant to alfalfa wilt; alfalfa "black stem" disease (*Phoma medicaginis*, with *Pleospora rehmiana* as perfect stage); and a survey of the southeastern part of the State for wheat smuts, and studies of stripe rust of barley in cooperation with the U. S. D. A. Bureau of Plant Industry.

Insects in relation to plant diseases, J. G. Leach (*Bot. Rev., 1 (1935), No. 11, pp. 448–466*).—This critical review from the Minnesota Experiment Station discusses the varied relationships of insects and plant diseases, insects in relation to virus and to nonparasitic diseases, the biologic and evolutionary significance of the association of insects and plant pathogens, symbiosis between insects and micro-organisms and its significance in plant pathology, the possible role of insects in the origin of new plant diseases and in the extension of old ones, and the future development of research in the field of insects in relation to plant diseases. The literature list includes 79 entries.

The problems of plant disease control (*Montana Sta. Rpt. 1934, pp. 40–42*).—This is a general statement of the purposes and accomplishments of the department of botany and bacteriology in investigations of poisonous plants and plant diseases and their control and in the identification and control of weeds. Wheat diseases, including barberry eradication, and virus diseases of

potatoes, tomatoes, sugar beets, and beans are briefly discussed, and reference is made to progress with the herbarium, which includes 12,000 specimens of fungi.

[Phytopathological studies by the New Jersey Stations] (*New Jersey Stas. Rpt. 1935, pp. 57, 62–71*).—Progress reports are given of studies relative to control of chrysanthemum wilt; potatoes, including tests of sprays for the control of diseases and insect pests; the effects of fertilizer materials and methods of application on yields and on the development of scab (including fertilizer placement studies in cooperation with the U. S. D. A. Bureau of Plant Industry, acid v. neutral fertilizer mixtures, magnesium and potash, and calomel applications with the fertilizer); the development of brown stem or *Rhizoctonia* of potatoes as influenced by soil moisture and by seed disinfection with mercuric chloride; soil applications of mercury compounds in the control of sweetpotato scurf; soil applications of lime and of calcium cyanamide in the control of clubroot of crucifers; the development and testing of sweet corn strains and varieties resistant to bacterial wilt; bacterial canker of tomatoes; tomato seed treatment with copper dusts; spraying for the control of cantaloup diseases and insect pests; the effects of fungicidal treatments on rhubarb roots; the control of lettuce drop (*Sclerotinia minor*); damping-off control with formaldehyde dusts; control of pea root rot (*Aphanomyces euteiches*) by fertilizers; the influence of soil type on the time of maturity of the apple scab fungus, and tests of various copper and sulfur sprays in scab control; ascopore discharge studies on *Mycosphaerella rubina* causing raspberry spur blight; the mechanism of copper injury to apple, peach, and grape leaves; control of *Verticillium* wilt of eggplants by calcium cyanamide and by production of resistant hybrids; *Verticillium* wilt in the Pink Seidewitz chrysanthemum and its control; the Dutch elm disease eradication work; control of black spot and brown canker of roses; fertilization in the control of maple wilt (*V. dahliae*); rhododendron wilt (*Phytophthora cinnamomi*); *Phomopsis* sp., *Valsa* sp., and *Pityogenes hopkinsii* as secondary invaders in cankers of *Pinus excelsa* induced by winter injury; mulberry (*Morus*) canker due to *Fusarium* sp., and its control; smilax leaf spot and canker due to *Fusarium* sp.; *Taxus* die-back due to *Phomopsis* sp.; root and stem rot of *Pinus resinosa*, its etiology and control; and blueberry (*Vaccinium*) diseases due to *Gloeosporium* and *Phomopsis*. Plant disease survey data are included.

Control of soil fungi by soil fumigation with chloropicrin, G. H. Godfrey (*Phytopathology, 26 (1936), No. 3, pp. 246–256, fig. 1*).—Laboratory experiments designed to determine the practical fungicidal value of chloropicrin used as a soil fumigant were conducted by the University of California, using 4-gal. glazed stone jars of soil. The fungi tested were *Fusarium* sp. from gladiolus, *Phytophthora cactorum* from snapdragons, *Rhizoctonia solani* from sugar beet, *Verticillium alboatrum* from strawberry, *Sclerotium rolfsii* from sugar beet, *Dematophora* sp. from apple roots, and *Armillaria mellea* from prune roots. The cultures were inserted 6 in. deep next to the wall of the jar, and chloropicrin was introduced into the center at the rate of 1.25 cc per jar (equivalent to 400 lb. per acre-foot). The jar was then sealed with gas-impervious, glue-coated paper and left for 48 hr.

Culture tests on nutrient agar were negative for all fumigated jars, while all controls were positive. Subsequent small-scale tests with greenhouse soils spontaneously infested with plant-disease fungi and a greenhouse ground-bed test with tomato *Verticillium* gave corroborative evidence. The practicability of disinfecting greenhouse potting soils in special boxes and of sterilizing laboratory glassware by chloropicrin fumigation is believed to have been demonstrated.

Seedling culture in sand to prevent damping off, A. A. DUNLAP (*Phytopathology, 26 (1936), No. 3, pp. 278–284, fig. 1*).—In studies by the Connecticut [New Haven] Experiment Station, a large variety of seedlings were grown in washed sand with nutrient salts added in solution at time of planting. Similar cultures with treated and nontreated soils were grown under the same conditions for comparison. The best damping-off control was obtained by the sand-culture method. Seedlings grown in sand compared favorably with those from soil and were more readily transplanted. Other desirable features in favor of sand culture were noted.—(*Courtesy Biol. Abs.*)

Diagnosis of plant troubles with diphenylamine, L. H. JONES (*Plant Physiol., 11 (1936), No. 1, pp. 207–209*).—In this study by the Massachusetts Experiment Station, the plant part chosen for nitrate tests with diphenylamine depended on the plant. Negative tests may be obtained if the region taken is actively utilizing nitrates. Misuse of fertilizers carrying nitrate may be determined by using the diphenylamine test on the injured tissue. There was some indication that the ammonium ion from $(NH_4)_2SO_4$ may be transformed to the less injurious nitrate ion.—(*Courtesy Biol. Abs.*)

The peptidase system of Aspergillus parasiticus, M. J. JOHNSON and W. H. PETERSON (*Jour. Biol. Chem., 112 (1935), No. 1, pp. 25–34, fig. 1*).—This is a contribution by the University of Wisconsin.

Persistence of Erwinia amylovora in certain insects, P. A. ARK and H. E. THOMAS (*Phytopathology, 26 (1936), No. 4, pp. 375–381*).—In these studies by the University of California, larvae of *Drosophila melanogaster* and *Musca domestica*, after feeding on a medium contaminated by *E. amylovora* [=*Bacillus amylovorus*], carried the organism in their internal organs through the pupal and to the adult stages. Eggs of *M. domestica* from contaminated females carried the organism only externally. Adults of *D. melanogaster, M. domestica*, and *Lucilia seriata* harbored it internally and excreted it in viable condition in the feces for 6, 3, and 4 days, respectively. The organism remained viable in the viscera of honeybees for 48 hr., but was not recovered from the feces at any time nor from the heads later than 12 hr. after the time of contamination.

Lepiota morgani in southern California, C. O. SMITH (*Mycologia, 28 (1936), No. 1, p. 86*).—This note is a contribution by the California Experiment Station.

A method for inoculating wheat and barley with loose smuts, M. B MOORE (*Phytopathology, 26 (1936), No. 4, pp. 397–400, fig. 1*).—In this method, developed by the Minnesota Experiment Station, inoculation is accomplished with an apparatus in which an entire head of wheat or barley is subjected to an alternating partial vacuum while submerged in an aqueous suspension of chlamydospores. The alternating vacuum displaces the air in the florets with inoculum. From 90 to 100 percent infection was obtained in wheat and from 2 to 76 percent in barley.

Further experiments on the control of barley smuts, R. W. LEUKEL (*U. S. Dept. Agr., Tech. Bul. 513 (1936), pp. 12*).—Continuing this series of studies (E. S. R., 64, p. 145; 67, p. 138), it was noted that in two consecutive years barley from fields badly infected with covered smut (*Ustilago hordei*) produced crops with very low percentages of smutted heads.

Inoculation by the evacuation method or by applying dry spores to the seed with subsequent incubation at from 25° to 28° C. under high humidity resulted in about two to three times as much covered smut as by application of spores by natural agencies only. Inoculation by the first method produced a higher percentage of covered smut than by the second method, and the disease was less easily controlled.

Ceresan and New Improved Ceresan completely controlled covered smut and black loose smut (*U. nigra*). Soaking the seed in a 1:320 formaldehyde solution for 1 hr. eliminated black loose smut and gave a fair but not complete control of covered smut. Formaldehyde dusts were not consistently effective, though some brands gave better control than others. None of the commercial dust fungicides used were injurious to the seed, even with storage for 5 mo. after treatment.

The effect of corn smut on the yield of grain in the San Joaquin Valley of California, F. L. SMITH (*Jour. Amer. Soc. Agron., 28 (1936), No. 4, pp. 257–265*).—In this study by the University of California, the "grain from 220 pairs of smutted and adjacent nonsmutted plants was weighed. Analyses of differences were made by Student's method. Losses from smut infection on the ear and below the ear were calculated for small, medium, and large galls. Losses due to multiple galls of a number of different combinations were calculated. Losses due to smut below the ear are estimated to be 7 percent for small, 19 percent for medium, and 47 percent for large galls. Ear infections gave greater losses, 23 percent for small, 41 percent, for medium, and 82 percent for large galls.

"The percentage of barren stalks increased with the amount of smut. In stalks with large galls on the ear, 52 percent were barren, while 35 percent were barren when large galls occurred below the ear. Single small galls produced no barren stalks, neither did medium galls below the ear, but medium galls on the ear caused 4 percent barrenness. Multiple small and medium galls caused an increase in the percentage of barren stalks. Two or more large galls produced 100 percent barren stalks.

"The estimated loss in yield in the field having 17.4 percent smutted plants was 6 percent."

Effect of crown rust on the composition of oats, H. C. MURPHY (*Phytopathology, 26 (1936), No. 3, pp. 220–234, figs. 2*).—This reports a study by the Iowa Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry relative to the effect of crown rust (*Puccinia coronata avenae*) infection on the yield and chemical composition of mature grain and green plants of susceptible and resistant oat varieties under greenhouse conditions.

Infection initiated in the anthesis stage on Markton (susceptible) and in the seedling, boot, and anthesis stages on Victoria (resistant) had no appreciable effect on the moisture, ash, fat, and fiber content of the kernels. There was a slight increase in protein and a corresponding decrease in nitrogen-free extract of the kernels of both varieties in relation to duration of infection. The composition of the oat hulls was not appreciably affected by the infection. The green weight of the susceptible varieties Markton and Iogold was reduced by 69.3 and 63.6 percent, respectively, as a result of infection, while the corresponding reductions for the resistant varieties Victoria and Bond were 22.2 and 14.7 percent, respectively. Concentrations of insoluble solids, ash, nitrogen, and acid-hydrolyzable substances in the green plant were all increased by the infection. Ammonia, amide, and nitrate and nitrite nitrogen showed the greatest percentage of increase. The increases in these noncolloidal nitrogen fractions for the susceptible Markton variety were 257.1, 327.3, and 322.0 percent, respectively, while the greatest increase for the colloidal or protein nitrogen was 25.8 percent. Corresponding maximum increases for insoluble solids and acid-hydrolyzable substances were 29.6 and 29.7 percent, respectively. The proportions of total soluble solids, sugars, and dextrin in the green plant were all decreased by the infection. The sugars showed the greatest decreases, sucrose, glucose, and levulose being

decreased by 83 6, 78.7, and 97.4 percent, respectively, in the infected Markton plants, while total soluble solids and dextrin showed a corresponding decrease of 19.3 and 23.3 percent, respectively.

A new Pseudodiscosia, R. SPRAGUE and A. G. JOHNSON (*Mycologia, 28 (1936), No. 2, pp. 181–185, figs. 2*).—In this paper, reporting a cooperative investigation by the Oregon and Washington Experiment Stations with the U. S. D. A. Bureau of Plant Industry, *P. avenae* n. sp. is described from a leaf spot of fall-sown oats (*Avena sativa*) occurring in the States of Oregon and Washington.

Can different degrees of bunt resistance be recognized in F_2 plants? A. M. SCHLEHUBER (*Jour. Amer. Soc. Agron., 28 (1936), No. 4, pp. 266–270, fig. 1*).—The results of this study by the Washington Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry are believed to show definitely that different degrees of bunt resistance can be recognized in F_2 plants. The data are evaluated from the standpoint of practical application to breeding for bunt resistance.

Reaction of certain varieties and species of the genus Hordeum to leaf rust of wheat, Puccinia triticina, C. O. JOHNSTON (*Phytopathology, 26 (1936), No. 3, pp. 235–245, fig. 1*).—Greenhouse experiments by the Kansas Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry, using seedlings, proved that varieties of cultivated barley and wild species of *Hordeum* differ in their responses to leaf rust of wheat. No variety or species was fully susceptible, but some permitted sporulation of the fungus. Among the cultivated barleys, varieties of the botanical group *H. intermedium cornutum* approached susceptibility. Of the 8 species of wild barley tested, *H. spontaneum, H. maritimum, H. bulbosum, H. gussoneanum,* and a strain of *H. murinum* bore reproductive infections. Several physiologic forms of the fungus were used, but differences in the reaction of the various varieties and species to them were only slight in most cases.

The greatest number of varieties and species bearing pustules occurred in the 14- and 28-somatic chromosome groups. *H. nodosum* (42 chromosomes) was highly resistant. This is the reverse of the condition in *Triticum*.

Bacteriophage as related to the root nodule bacteria of alfalfa, S. C. VANDECAVEYE and H. KATZNELSON (*Jour. Bact., 31 (1936), No. 5, pp. 465–477, figs. 2*).—In this study by the Washington Experiment Station, a potent lytic principle active against four out of five laboratory cultures of *Rhizobium meliloti* was isolated from each of two soils from the Yakima district carrying 3-year-old alfalfa stands. Further study of soil and plant samples from 20 alfalfa fields failed to reveal bacteriophage from soils carrying plants less than 3 yr. old. The most common source of the bacteriophage was the soil from fields growing alfalfa off and on for many years and carrying 3- and 4-year-old stands. Indications of the presence of the lytic principle were found in the nodules regardless of the age of the plants. In general, nodulation was poor on plants in fields carrying the bacteriophage.

One of the isolations caused complete dissolution of a 24-hr. fluid culture of *R. meliloti* at a dilution of $1:10^9$ and partial clearing at $1:10^{11}$. The transmissibility of the isolation from one of the soils was demonstrated in fluid cultures and by means of plaques.

It is deemed possible that bacteriophage may be responsible for reduced yields, but definite conclusions are reserved pending further investigation.

Discussion of disease-free and disease-resistant beans, J. C. WALKER (*Canning Age, 17 (1936), No. 4, pp. 171, 172, 178*).—This is a contribution by the Wisconsin Experiment Station.

The diurnal cycle of the powdery mildew, Erysiphe polygoni, C. E. YARWOOD (*Jour. Agr. Res.* [*U. S.*], *52* (*1936*), *No. 9, pp. 645–657, fig. 1*).—In this cooperative study between the U. S. D. A. Bureau of Plant Industry and the University of Wisconsin, conidia of clover mildew (*E. polygoni*) placed on dry glass slides in the dark germinated best when removed from diseased field or greenhouse plants during the light portion of the day and germinated poorly when removed at night. The germination of conidia taken at night was greatly increased when they were exposed to light or placed on host leaves. In each conidiophore one conidium was matured about noon, and the generative cell divided in the late afternoon. In the field, dissemination of conidia occurred most actively during the light portion of the day. The mycelium grew at a fairly uniform rate throughout the day and night, but appressoria were formed principally in the light. Inoculations were more successful during the light portion of the day than at night. Mildewed leaves transpired more actively than healthy leaves at night, but equal to or less than normal leaves during the day. Tests of these cyclic phenomena in chambers where light was the only environmental factor known to vary throughout the day indicate that alternation of light and darkness is responsible for this diurnal periodicity. A similar diurnal cycle was indicated for forms of *E. polygoni* on red clover, delphinium, and cabbage, but none was established for *E. graminis* on barley.

Host range and physiologic specialization of red clover powdery mildew, Erysiphe polygoni, C. E. YARWOOD (*Jour. Agr. Res.* [*U. S.*], *52* (*1936*), *No. 9, pp. 659–665, fig. 1*).—In this joint study from the U. S. D. A. Bureau of Plant Industry and the Indiana Experiment Station, the susceptibility of 20 *Trifolium* spp. to *E. Polygoni* was determined by tests in the field, greenhouse, and laboratory, 14 proving susceptible in varying degree. Of these, *T. lupinaster*, *T. carolinianum*, *T. striatum*, *T. reflexum*, *T. angustifolium*, *T. panormitanum*, *T. squarrosum*, *T. resupinatum*, *T. subterraneum*, and *T. repens* are believed to be new records of hosts susceptible to this fungus.

From several collections secured from various parts of the United States and from Canada, three physiologic forms were distinguished. It appears from these limited tests that form 1 is widely prevalent, and that forms 2 and 3 are relatively rare. Moreover, since these three forms are similar, they are probably all of the epidemic type which spread so rapidly from the East to the West of the United States from 1921 to 1924. Since powdery mildew of clover was present in the United States previous to 1921, this earlier mildew probably differed from those here studied.

The tests of host susceptibility and of physiologic forms were greatly facilitated by a method of growing the fungus on living, excised leaves floating on sucrose solution.

A study of Stewart's disease of sweet corn caused by Phytomonas stewarti[i], C. W. FRUTCHEY (*Michigan Sta. Tech. Bul. 152* (*1936*), *pp. 25, figs. 5*).—This monograph gives a rather full review of the work of previous investigators of this disease. Its great economic importance is stressed, and the symptoms are described in detail. The author was never able to isolate the causal organism from the soil or from the embryo of the seed, but he obtained it repeatedly from the extraembryonic parts of seed from diseased plants. Fully controlled experiments appeared to indicate conclusively that the organism within the vascular tissue at the kernel base is unable to invade the embryo at the time of germination unless some injury has occurred that would afford an avenue of entrance.

Conclusive experimental proof is presented, including repeated isolations of *P. stewartii*, both externally and internally, from larvae of the seed-corn

maggot (*Hylemyia cilicrura*), that this maggot can and does carry the organism from the infected to the uninfected part of the seed. The fact that the maggot attacks corn plants and also carries the organism internally in a virulent form is conclusive evidence of its role in the dissemination of Stewart's disease. Proof is also given that the common wheat wireworm (*Agriotes mancus*) may act as a mechanical carrier of inoculum, though the organism was never isolated from its internal parts. Wireworms are considered of minor importance in the field because of their low incidence (except in soddy soil), and of their apparent inability to harbor the bacterium for any length of time. From the above evidence, together with that presented by Rand and Cash (E. S. R., 69, p. 663) and by Poos and Elliott (E. S. R., 73, p. 325) with reference to dissemination by flea beetles, it is concluded that insects play an important role in the spread of the disease.

A *Fusarium* and a white bacterium (unnamed, but possibly related to *P. dissolvens*) were sometimes found associated with *P. stewartii*. The fungus causes a foot rot, but is not believed to be an important factor in Stewart's disease because it is so virulently parasitic as to overshadow the effects of *P. stewartii*. Experiments indicated that the white bacterium may be very important in the spread of (and in causing wilt symptoms resembling) Stewart's disease, since it can attack and rot away the tissues, thus allowing *P. stewartii* to gain an entrance into the vascular system of the seed.

Other than by the use of resistant varieties, there are no known methods for control. As shown also by various other workers, surface sterilization of infected seed proved ineffective, and no successful method of sterilizing the interior of the seed without embryo injury was found by the author.

As general results of the investigation, it is concluded that infected seed, insect transmission, and organisms associated with *P. stewartii* are the main factors influencing the development of Stewart's disease. Though *P. stewartii* can be isolated from seed developed on affected plants, few or no wilted plants develop from this infected seed in the absence of other factors, due to the fact that the organism is not found in the embryo and is unable to penetrate unaided from the chalazal region into the vascular tissue of the young seedling. Insects feeding on the roots and old kernels of the seedling may spread the disease by themselves carrying the organism or by contact spread in the case of infected seed. Morphological and other data lead the author to believe that general infection of a corn plant with *P. stewartii* occurs at the base of the plant, where large numbers of vascular bundles are involved, whether the inoculum is in the seed or is carried by insect larvae.

Longevity of sclerotia of Phymatotrichum omnivorum in moist soil in the laboratory, J. J. TAUBENHAUS and W. N. EZEKIEL (*Amer. Jour. Bot., 23 (1936), No. 1, pp. 10–12, fig. 1*).—Tested at yearly intervals by the Texas Experiment Station, sclerotia stored in the laboratory in soil of from 20 to 40 percent moisture content gave 12 percent germination after 5 yr., produced normal growth in media and soil, and caused typical root rot on cotton.

Insects as possible distributors of Phymatotrichum root rot, J. J. TAUBENHAUS and L. D. CHRISTENSON (*Mycologia, 28 (1936), No. 1, pp. 7–9*).—From this preliminary cooperative study by the Texas Experiment Station with the U. S. D. A. Bureau of Entomology it appears that insects are probably not involved in the spread of *P. omnivorum*.

Phymatotrichum root rot on winter and spring weeds of south central Texas, J. J. TAUBENHAUS (*Amer. Jour. Bot., 23 (1936), No. 3, pp. 167, 168*).—Studies made by the Texas Experiment Station clearly showed that *P. omnivorum* can survive on 14 different winter and spring weeds normally growing in

fallow fields and in fields devoted to permanent cotton or to corn. Such weeds may act as bridging hosts, enabling root rot to spread to succeeding cotton crops or to summer annual and perennial weeds which are nearly always present in corn or fallow fields.

Fertilize to control cotton wilt and rust, V. H. YOUNG (*Better Crops With Plant Food, 20 (1936), No. 7, pp. 13–16, 37–40, figs. 6*).—This contribution by the Arkansas Experiment Station summarizes experiments leading to the conclusion that cotton wilt and rust can be almost completely eliminated, provided root knot is absent, if a resistant variety is employed and enough potash is applied to control rust or potash hunger.

Potash for cotton wilt and rust in south Mississippi, L. E. MILES (*Better Crops With Plant Food, 20 (1936), No. 9, pp. 6–8, 41–44, figs. 3*).—As a result of the studies by the Mississippi Experiment Station here reported, a sound basis for control of cotton rust and wilt is attained. Rust can be controlled by the use of a fertilizer containing an adequate amount of potash, and measures increasing the humus content of the soil are also beneficial. A suitably adapted variety with at least moderate resistance is advised for wilt control, and an increased amount of potash is also an aid.

Seed-potato treatment for Rhizoctonia control in northeastern Maine, 1929 to 1933, W. P. RALEIGH and R. BONDE (*Phytopathology, 26 (1936), No. 4, pp. 321–343*).—In this cooperative study between the U. S. D. A. Bureau of Plant Industry and the Maine Experiment Station, various standard and new materials were tested for *Rhizoctonia* control. Seed-tuber treatment of infected Irish Cobblers usually increased the stand, heightened the average vigor of the plants, reduced the injury from stem lesions and the percentage of infected tubers, and increased the yield. Treatment of clean Irish Cobblers and field-run Green Mountains failed to increase the yield. The acidulated corrosive sublimate ($HgCl_2$ 1–500, with 1 percent HCl) 3-min. treatment was satisfactory for *Rhizoctonia* control, but it appeared somewhat more dangerous as to injury than the standard $HgCl_2$ treatment. A solution of $HgCl_2$ 1–1,200 with potassium iodide 1–400, used as a dip treatment, gave promising results. The organic mercury dips used were slightly inferior to the standard $HgCl_2$ treatment. Clean Irish Cobblers planted in a separate experiment, either treated or not, produced a crop bearing very few *Rhizoctonia* sclerotia.

A method for the isolation of Actinomycetes from scab lesions on potato tubers and beet roots, C. F. TAYLOR (*Phytopathology, 26 (1936), No. 4, pp. 387, 388*).—In this contribution by Cornell University the following procedure is given: A mixture of 3 parts of calcium hypochlorite (10 g shaken in 140 cc tap water and filtered) and 1 part of sodium hydroxide (250 g dissolved in water and made up to 1,000 cc) stock solutions is used as the disinfectant. Scabby tubers are held in this mixture for 2 min., removed, and without washing a section of a lesion is triturated in a few drops of sterile water. Plated in S. A. Waksman's egg albumin agar, the resultant suspension gives a relatively pure culture of *Actinomyces*.

Soil actinomyces and potato scab, B. F. LUTMAN, R. J. LIVINGSTON, and A. M. SCHMIDT (*Vermont Sta. Bul. 401 (1936), pp. 32, pls. 4, figs. 20*).—A rather full review of the published work on potato scab and discussions of the methods of soil counts and plating out of the micro-organisms are presented, including the differentiation of two groups of actinomyces as colorless and brown-producing, respectively, on media.

Susceptible potato varieties were grown during the period 1914–17 on two field plats to determine their resistance to potato corky scab, with the result that almost 100 percent of badly scabby tubers were produced in 1916 on one

of these soils (a sandy loam) and almost as much on the other (a heavy clay loam). The sandy loam was not in potatoes between 1916 and 1934, timothy, corn, soybeans, and oats being grown thereon. A portion of the clay plat was planted twice to potatoes during this period. Beginning in 1924, bacterial counts were made by the plating-out method (1–1,000,000 dilution) during 8 yr. The total numbers of organisms and of actinomyces and the soil moisture contents were determined monthly, counts being based on 1 g of dry soil.

The total numbers of organisms were highest during winter, when the soil moisture was also highest, the rise beginning in November and the high counts continuing until April. The lowest totals were from May to October, inclusive, when the soil moisture was also at a low ebb. The actinomyces counts roughly paralleled those of the total numbers of organisms. During the 8 yr. the numbers of actinomyces neither increased nor diminished, remaining relatively stable though varying somewhat from year to year. An equilibrium apparently existed between the numbers and relative proportions of the actinomyces and the other organisms. The actinomyces in the soil existed mainly in the form of bits of mycelium (spores being relatively few), and the numbers as determined on the slides and by plate counts were reasonably concordant. In both soils the bacteria occurred mostly in the vegetative state, and the spore numbers and percentages followed closely the total numbers of organisms month by month. The spores of the soil bacteria failed to color with any of the differential spore stains, although they were physiologically spores in their temperature resistance.

Disinfected Green Mountain potato seed was planted on the sandy loam soil after an absence of potatoes for 19 yr., and gave yields (1935) of 70.2 percent clean, 26.5 slightly scabby, and 3.3 percent badly scabby. The corresponding yields for the 1916 crop had been 0.0, 0.8, and 99.2 percent, respectively.

The loss from once infected soil of pathogenic species of actinomyces which will produce typical, deep scab might be explained as follows: (1) the pathogenic species or strains may have died out in the soil from lack of a suitable host. (2) Many species or strains may have pathogenic tendencies but, with no suitable host present, may lose them. They may regain these pathogenic habits if a suitable host is later provided. The first indications of the return of the disease is its reappearance in a milder form, which in the case of potato scab would be a russeting. The senior author is inclined to believe that the second hypothesis is more likely to represent the truth.

Disease resistance tests and seedling selections in 1935 at the U. S. Sugar Plant Field Station, Houma, La., E. V. Abbott, E. M. Summers, and R. D. Rands (*Sugar Bul., 14 (1936), No. 12, pp. 3–7*).—The authors report notable progress in the search for new sugarcane varieties possessing superior qualities of disease resistance, sugar yield, and economical handling, and a brief summary of the disease resistance tests and primary selection work is given.

Possible chemical nature of tobacco mosaic virus, C. G. Vinson (*Science, 79 (1934), No. 2059, pp. 548, 549*).—It is reported in this contribution by the Missouri Experiment Station that under the experimental conditions "purified virus preparations which seemed to contain the major portion of the original virus have not yet been obtained free of nitrogen."

A tobacco hybrid useful for virus studies, J. Johnson (*Amer. Jour. Bot., 23 (1936), No. 1, pp. 40–46, figs. 7*).—In this contribution by the Wisconsin Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry, the behavior of ordinary tobacco mosaic virus was studied on the first generation of *Nicotiana tabacum* × *N. glutinosa*, an apparently sterile hybrid

morphologically resembling *N. tabacum*. In the latter parent the characteristic infection is systemic without primary necrotic lesions, while in *N. glutinosa* the opposite is true. The hybrid resembles the latter in its reaction to the virus, but infection may become systemic, so that it is then relatively simple to trace the path of the virus. All the tissues of the leaf and stem may be invaded, but the xylem appears least likely to be affected. The first signs of infection often appeared in the cambium or pericycle. The phloem thus seems to have no special relation to the virus movement. The most favorable temperature for virus multiplication was apparently around 22° to 24° C. Spraying the virus on the leaves of the hybrid gave but few local lesions, indicating the rarity of stomatal invasion.

Aphid transmission from tomato to the hybrid is shown by the necrotic lesions produced. In this way it was found that less than 1 percent of the three aphid species used transmitted the virus from tomatoes.

The hybrid is apparently less susceptible than *N. tabacum* to ordinary tobacco mosaic but possesses advantages over both parents for certain types of virus study. It was also found susceptible to several other viruses.

Inheritance of resistance to root rot in tobacco caused by Thielavia basicola, T. C. McIlvaine and R. J. Garber (*Jour. Amer. Soc. Agron., 28 (1936), No. 4, pp. 279–283, fig. 1*).—The results of this study by the West Virginia Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry indicate resistance of tobacco to *T. basicola* to be heritable as a dominant or partially dominant characteristic.

Tobacco streak, a virus disease, J. Johnson (*Phytopathology, 26 (1936), No. 3, pp. 285–292, figs. 3*).—Tobacco streak, a relatively rare disease, shown by cooperative studies between the Wisconsin Experiment Station and the U. S. D. A. Bureau of Plant Industry to be due to a virus, is characterized by striking necrotic patterns on the leaves, which usually have a close relation to the veins. A marked tendency to recovery from symptoms is noted.

The virus is mechanically transmissible by plant extracts, but no insect vector has yet been demonstrated. Its survival time in vitro is less than 36 hr. at 22° C., its thermal death point 53°, and its tolerance to dilution less than 1 in 30. Several other solanaceous species are susceptible to the virus, while others (e. g., tomato) are apparenly immune.

Physalis subglabrata: A natural host of Bacterium angulatum, W. D. Valleau and E. M. Johnson (*Phytopathology, 26 (1936), No. 4, pp. 388–390*).—*P. subglabrata* plants collected from pastures and fence rows 2 mo. after tobacco had been harvested on the Kentucky Experiment Station farm were infected with *B. angulatum* [=*Phytomonas angulata*], and in one case a single colony isolation gave two strains of *B. tabacum* [=*P. tabaci*] differing in colony characters. The evidence seemed sufficient to prove that *Physalis subglabrata* is a natural host of *B. angulatum* and probably also of *B. tabacum*. This and perhaps other solanaceous weeds must be considered in future epiphytological studies of these diseases.

Resistance to Cladosporium fulvum, E. F. Guba (*Phytopathology, 26 (1936), No. 4, pp. 382–386*).—In this contribution by the Massachusetts Experiment Station, it is reported that the tomato varieties Maincrop, Norduke, Up-to-Date, Norton, and certain hybrids obtained from England have shown some degree of resistance to the fungus, but hybridization within these varieties has failed to yield lines sufficiently resistant to be considered of commercial value. The currant tomato (*Lycopersicum pimpinellifolium*), which is immune, has been hybridized with large-fruit tomato sorts, and the progress of the work indicates the probability that large-fruit tomatoes completely resistant to this leaf mold will be developed.

A review of the pertinent literature and a bibliography of 37 titles are included.

New wilt-resistant tomatoes for Illinois, W. A. HUELSEN (*Canning Trade, 58 (1936), No. 35, pp. 10–12*).—As a result of 10 yr. of breeding work by the Illinois Experiment Station, three new field varieties (Prairiana, Early Baltimore, and Illinois Pride) resistant to *Fusarium* wilt have been isolated and are here described. They are now being released to the public.

Florida has wilt resistant watermelon, J. THOMAS (*Fla. Grower, 45 (1936), No. 2, p. 7*).—This is a popular account of the Leesburg variety developed by the Florida Experiment Station.

Effect of magnesium deficiency on the growth of vegetables, R. L. CAROLUS (*Veg. Growers Assoc. Amer. Ann. Rpt., 1935, pp. 97–103*).—This general account of the magnesium deficiency disease is a contribution by the Virginia Truck Experiment Station, in which are included data on the effects of additions of magnesium on the growth, yield, and composition of various truck crops, the characteristic types of injury from magnesium deficiency in these crops, prevention of this deficiency by additions of magnesium-containing salts (including specific recommendations), and on the magnesium requirements of various truck plants (including the amounts lost in the harvested crops).

Seed-borne diseases of vegetables, O. C. BOYD (*Veg. Growers Assoc. Amer. Ann. Rpt., 1935, pp. 219–230*).—This contribution by the Massachusetts State College gives a general discussion of these diseases and their control.

The value of "insoluble" coppers in vegetable disease control, J. D. WILSON (*Ohio Veg. Growers' Assoc. Proc., 21 (1936), pp. 99–104*).—The results expressed in this contribution from the Ohio Experiment Station suggest that some of the insoluble copper compounds now available may be used advantageously on crops which are frequently injured or stunted by bordeaux mixture and in which disease control is not especially difficult. Basic copper chloride offers promise for tomatoes, and this or Coposil are recommended for cucumbers. "Either of these compounds could probably be used to advantage as substitutes for dry bordeaux when only a small amount of spray is to be prepared, as in the home garden."

Important considerations in control of diseases of greenhouse vegetables, E. F. GUBA (*Veg. Growers Assoc. Amer. Ann. Rpt., 1935, pp. 251–258*).—This contribution by the Massachusetts Experiment Station offers some of the important developments and recommendations relative to the control of greenhouse vegetable diseases. "A planned program of disease control must include proper rotation and supply of soil nutrients, manure, and the proper soil reaction considered best for the particular crop being grown."

Some problems and principles of orchard disease control, with special reference to sanitation and related measures, G. W. KEITT (*Jour. Econ. Ent., 29 (1936), No. 1, pp. 43–52*).—This contribution by the Wisconsin Experiment Station is one in a symposium on orchard sanitation, briefly discussing the more important phases of the subject and giving fuller data on apple scab control as an illustrative problem.

The honeybee and the beehive in relation to fire blight, E. M. HILDEBRAND and E. F. PHILLIPS (*Jour. Agr. Res. [U. S.], 52 (1936), No. 10, pp. 789–810, figs. 2*).—The results of these studies over four seasons by the [New York] Cornell Experiment Station indicate that *Erwinia amylovora* [=*Bacillus amylovorus*] is incapable of overwintering in the beehive or in association with the honeybee. When introduced in the food of the bees, the fire blight bacteria were not reisolated after 3 days from such locations as honey, comb, frame, and bees. In only two cases was recovery made after 3 days from the time

contaminated food was taken, viz, from pollen at 13 days and from frame scrapings at 12 days.

The bacteria survived for relatively short intervals (from 1 day to several weeks, depending on the kind of sugar and the temperature) at sugar concentrations of 30 percent or over, covering the range from heavy nectar to honey that would be found in the hive, and they ordinarily survived longest at the lower temperatures. Of the materials used, sucrose solution had the least bacteriostatic and bactericidal effect. With a synthetic culture solution as the base, the maximum sugar concentrations at which the organism grew in dextrose, levulose, artificial nectar, and sucrose, were, respectively, 30, 30, 35, and 58 percent. These data indicate that survival of *E. amylovora* in the hive is highly improbable at the temperatures and sugar concentrations normally encountered there.

The bacteria were not found associated with the immature stages in the honeybee life cycle, even though an abundance was present in the food of the bees at all times during the rearing of the brood. The honeybee was found to function in two ways, viz, (1) in carrying the bacteria from the hive to the flowers, and (2) in the dissemination of inoculum from flower to flower. Transfer of inoculum from hive to flowers was conditioned, however, on the bees actively feeding on contaminated food.

Persistence of Erwinia amylovora in certain insects, P. A. ARK and H. E. THOMAS (*Phytopathology, 26 (1936), No. 4, pp. 375–381*).—The results of an investigation of the biological transmission of the fire blight organism (*E. amylovora*) under laboratory conditions by the pomace fly, housefly, green-bottle fly *Lucilia sericata*, and honeybee are reported. Larvae of the pomace fly and the housefly after feeding on a medium contaminated by *E. amylovora* were shown to contain the organism in their internal organs. The bacteria persisted through the pupa to the adult in both of these insects. Eggs of the housefly from contaminated females carried the organism externally but not internally. Adults of the pomace fly, housefly, and green-bottle fly harbored the organism internally for 6, 3, and 4 days, respectively. The bacteria remained viable in the viscera of honeybees for 48 hr. but were not recovered from the heads after 12 hr. from the time of contamination.

A review of the apple disease situation, H. C. YOUNG (*Ohio State Hort. Soc. Proc., 69 (1936), pp. 16–18*).—This contribution from the Ohio Experiment Station gives a summary of apple disease conditions in the State for 1935, with special reference to scab, cedar rust, frogeye or black rot, and bitter rot, and including data on the results of spray treatments.

What fungicides should be used for apple diseases in 1936? H. W. ANDERSON (*Ill. State Hort. Soc. Trans., 69 (1935), pp. 441–456*).—In this contribution by the University of Illinois, the "Illinois spray schedule" is recommended, with minor changes under certain conditions. Spray materials for scab and for diseases other than scab and "the 1936 spray schedule" are briefly discussed.

Some environmental factors influencing the development of hairy root on apple, A. J. RIKER, D. H. PALMITER, and E. M. HILDEBRAND (*Jour. Agr. Res. [U. S.], 52 (1936), No. 9, pp. 715–721, figs. 4*).—In studies at the Wisconsin Experiment Station, "inoculations with *Phytomonas rhizogenes* [=*Bacterium rhizogenes*] were made on 1-year-old Fameuse apple trees kept at graduated soil temperatures and soil moistures. The highest incidence of infection, in the time of the experiment, appeared at 24° to 28° C., and at 60 and 75 percent of the moisture-holding capacity of the soil. This probably indicated the shortest incubation period. The growth of the shoots in length was greatest

at 20°, with vigorous growth between 16° and 28°. Their growth was also more vigorous at 75 and 90 percent soil moisture than at 60 percent. The development in weight of hairy root was greatest at 24° to 28°. It was good over the entire range and only slightly greater at 75 and 90 percent moisture than at 60 percent. The air temperature was approximately 24°.

"The growth of the hairy root bacteria was measured by colony diameter on yeast-infusion and carrot agar, and by turbidity in a yeast-infusion liquid medium, at temperatures from 4° to 36°. Vegetative growth was greatest at 28°, good at 16°, 20°, 24°, and 32°, moderate at 8° and 12°, and slight at 4° and 36°."

Apple scab, A. B. GROVES (*Va. Fruit, 24 (1936), No. 3, pp. 10, 12, 14, 16–18, fig. 1*).—This contribution from the Virginia Experiment Station describes the disease, gives the developmental cycle of the fungus, and discusses varietal differences in susceptibility and control measures.

The newer modified spray formulas in apple scab control, F. H. BALLOU and I. P. LEWIS (*Ohio State Hort. Soc. Proc., 69 (1936), pp. 43–54*).—This contribution from the Ohio Experiment Station gives a general discussion of the spray materials and formulas and other factors important for success in the control of scab. Special reference is made to the materials and formulas for use on varieties (1) susceptible to scab and not easily russeted, and (2) not susceptible to scab but easily russeted. Some of the more important apple varieties are listed with their classification as to susceptibility to scab and russeting, and suitable spray formulas for each class are given. Tabulation and discussion of the results of spray experiments under Ohio conditions are also included.

Apple scab spraying results at Lafayette in 1934 and 1935, C. L. BURKHOLDER (*Hoosier Hort., 18 (1936), No. 5, pp. 75–77*).—This contribution by the Indiana Experiment Station details the local conditions relative to scab in 1934 and 1935, including the results of the spray schedules used. These indicated that scab is easily controlled under conditions of light carry-over, but that, even so, at least one pre-bloom application is necessary.

"Observations on scab control in 1935", W. C. DUTTON (*Mich. State Hort. Soc. Ann. Rpt., 65 (1935), pp. 25–28*).—This contribution by the Michigan Experiment Station is an address setting forth the results of spray tests in two Michigan localities. Tests on Dutchess and Jonathan apples at South Haven indicated 1 gal. of liquid lime-sulfur, 4 lb. of dry lime-sulfur, or 4 lb. of flotation sulfur to 100 gal. of water to be the smallest amounts that could have been used without a serious falling off in control. At these concentrations, from 94 to 100 percent of the fruits were scab free on the susceptible Dutchess variety. Kolofog at 9 lb. per 100 gave 77 percent control, and at 6 lb. to 100 it gave 64 percent control.

In the experiment on Dutchess apples at Grand Rapids, 1 gal. of liquid lime-sulfur gave 97 percent control, 4 lb. of electric sulfur 94 percent, and 4 lb. of flotation sulfur 96 percent control. Unsprayed trees here had 92 percent of scabby fruit, and at South Haven 100 percent.

Dusting for the control of apple scab, H. H. WHETZEL (*Ill. State Hort. Soc. Trans., 69 (1935), pp. 217–223*).—This contribution from Cornell University is a semipopular address summarizing present knowledge concerning spraying v. dusting, including the author's own experience, in the control of apple scab.

A new imperfect fungus, A. G. PLAKIDAS and C. W. EDGERTON (*Mycologia, 28 (1936), No. 1, pp. 82–84, fig. 1*).—In this contribution from the Louisiana Experiment Station the authors describe *Dendrosporium* n. g. (Moniliaceae

Hyalodidymae), with *D. lobatum* n. sp. saprophytic on dead or dying bark of pear (*Pyrus serotina*).

Brown rot of stone fruits on the Pacific coast and its control, B. A. RUDOLPH (*Better Fruit, 30 (1936), No. 10, pp. 3–5, figs. 2*).—This contribution from the University of California Deciduous Fruit Station, San Jose, describes the types of brown rot producing, under Pacific coast conditions, blossom and spur blights, branch cankers, and fruit rot, and outlines control measures developed from experimental work. Sanitary measures for the destruction of hold-over stages are advised. For the control of blossom infection growers are advised to spray with bordeaux mixture when fruit buds first show the color of the petals, with sometimes a second spray shortly after the first blossoms open. For brown rot of the fruit, spraying or dusting with finely divided sulfur is recommended whenever the disease begins to appear. In any case a precautionary application is advised 3 or 4 weeks before harvest. Sulfur is not recommended for apricots because of the danger of injury.

The proper timing of sprays for fungus diseases of stone fruits, C. E OWENS (*Oreg. State Hort. Soc. Ann. Rpt., 27 (1935), pp. 102–105*).—This general paper by the Oregon Experiment Station emphasizes the importance of proper timing of spray applications.

Cherry leaf curl and root injury, L. R. LANGFORD (*Amer. Soc. Hort. Sci. Proc., 31 (1934), pp. 252, 253, fig. 1*).—In this preliminary report by the Wisconsin Experiment Station, a curling of the leaves suggestive of drought injury has been associated with a root condition thought to be due to winter injury.

Prune die-back, O. LILLELAND (*Better Crops With Plant Food, 20 (1936), No. 10, pp. 17–19, 37, 38, figs. 4*).—These studies by the California Experiment Station at Davis began after the observation of a sudden scorching of the leaves and dying back of the branches of well-grown Agen (French) prune trees in the Sacramento Valley in 1917, the first symptoms often appearing during the summer of the first heavy crop. Tests of the soils indicated a lack of, and a marked ability to absorb or fix, potassium. Fixation by the surface soil when potash fertilizers were broadcast prevented a remedying of the situation by this procedure, but the problem was solved by the development of a soil-injection method using ordinary pipe fittings and a spray outfit giving adequate pressure for the introduction of potash solutions around the trees to a depth of 3 ft. The ameliorating effect on die-back was very striking, but the productivity of the treated orchard was in no case maintained, indicating that factors other than the potash content of the soil must be considered. One of these factors was the marked tendency of trees in the die-back areas to set very heavy crops, and in the better orchards it was possible to prevent leaf scorching and die-back by removing the crop rather early or by severe pruning.

Peaches and almonds on these soils exhibited no definite signs of injury, but when grafted to prunes the symptoms of die-back became manifest. An affected 7-year-old prune tree removed to a better soil recovered, and independent tank experiments by Hoagland and Chandler (E. S. R., 70, p. 476) have confirmed the supposition that the disease is distinctly a nutritional (potash deficiency) trouble of prune trees. However, the failure to secure complete recovery in the field by the use of potassium salts is still a challenge. It is possible that the heavy cropping may result in a weakened root system deficient in carbohydrates and lacking the energy to extend and avail itself of the added potassium.

[The Columbian purple raspberry carries the virus causing mosaic in red and black raspberries] (*Farm Res. [New York State Sta.], 2 (1936), No. 4, p. 12*).—This is a brief note of a recent finding.

Chlorine in relation to ring-neck in avocado fruits, A. R. C. HAAS (*Calavo News, 1936, June–July, pp. 12, 13, fig. 1*).—This disease usually occurs on the fruit pedicel and consists of dry surface areas more or less separating from the living tissue and leaving a scar. Chemical analyses at the California Citrus Experiment Station indicated that the stem half of the pulp or skin contained more total chlorine than the tip half, and the inner part of the pulp more than the outer part. A relation was also shown between the chlorine content of the irrigation water, the condition of the trees, and the chlorine content of the pulp and skin of the fruits. Severe tipburn and defoliation also accompanied high chlorine conditions. Further analyses of ring neck and normal fruits indicated a much higher chlorine content in the former. There is thus some reason for assuming that possibly chlorine or other salts are factors associated with ring neck disease.

Blight: A non-parasitic disease of citrus trees, A. S. RHOADS (*Florida Sta. Bul. 296 (1936), pp. 64, figs. 20*).—Following discussions of the history of citrus blight, etiological theories, economic importance, distribution, and detailed description of the symptoms, the results of a 12-yr. study of the disease are presented.

Blight is a chronic wilt and decline, usually starting on one side of a tree and progressing over the entire top. It is essentially a disease of older groves. Although causing heavy losses in some localities, in general, it must be regarded as a comparatively unimportant trouble in Florida. Blighted trees obviously die back as a result of failure of the root system to support the tops rather than from any attack on the top itself. No organism that could be regarded as the cause has ever been found, and it has been clearly demonstrated that the disease is not transmitted in the budwood, apparently indicating that it is not due to a virus. Trees replacing blighted ones lived about as long as the original trees, and did not appear to be more subject to blight than those set on virgin land under similar conditions. The incidence of blight seems to be correlated definitely with soil and soil moisture conditions, including both deficits of moisture on the lighter soils and excesses on the lower, poorer drained ones, and combinations of these two extremes. It occurs most frequently on the lighter, droughtier types of high hammock soils closely underlain with rock. All available evidence appears to confirm the conclusions that blight is caused by extreme fluctuations of soil moisture, and extended observations have indicated that the physical structure of the soil, kind of rootstock, and grove management are contributing factors.

A less frequent but more or less identical chronic wilt and decline of citrus trees, likewise regarded as blight by growers, has been attributable to injury of the roots after prolonged saturation of the soil during unusual rises in the water table, and in some locations the trouble has been intensified by droughty periods following such rises, and the converse. Blight must therefore be regarded as a composite trouble.

Control must be effected by the application of preventive rather than remedial measures. Despite years of trial, no known method of treatment (including irrigation) has succeeded in effecting a permanent recovery. After the trouble develops, the only recourse is to remove the affected trees as soon as they cease to become profitable and to replant.

Citrus bronzing—a magnesium deficiency, O. C. BRYAN and E. F. DEBUSK (*Fla. Grower, 45 (1936), No. 2, pp. 6, 24, figs. 3*).—In soil amendment trials by the Florida Experiment Station, stimulative effects and alleviation of leaf discoloration in both citrus and crotalaria followed the use of magnesium lime as compared with regular lime or no treatment. Chemical analyses of the

leaves of both plants indicated a higher content of magnesium and calcium under the magnesium lime as compared to the other plats. Magnesium apparently affects the calcium assimilation.

It appears from these tests that the citrus "bronzing" and the crotalaria failures are in many cases due to a deficiency of available magnesium, and that from 300 to 500 lb. of magnesium lime per acre per year would alleviate both conditions.

Progress on the control of citrus chlorosis or decline, A. H. FINCH, D. W. ALBERT, and A. F. KINNISON (*Amer. Soc. Hort. Sci. Proc., 31 (1934), pp. 20–23, fig. 1*).—This paper gives the symptoms of a chlorosis of various plants, among which citrus is of greatest economic importance, described as "probably the most important physiological disease of citrus in Arizona." Progress reports are given on attempts to find a satisfactory means of applying the iron therapy and to determine a means of rendering the iron held in the plant available to the growing tissues. The disease differs from "mottle-leaf" in that young trees are rarely affected, the disease becoming more severe as the trees become older. The continued response of citrus trees in advanced stages to iron appears to indicate that the specific cause is in some way related to the iron metabolism.

Recommended practice for control of carnation blight and wilt, E. F. GUBA (*Florists' Rev., 77 (1936), No. 1995, pp. 13, 14*).—This is a contribution from the Massachusetts Experiment Station.

Control of chrysanthemum diseases described in detail, L. M. MASSEY (*Florists' Rev., 75 (1934), No. 1933, pp. 15–18, figs. 2*).—This contribution from the [New York] Cornell Experiment Station is a general summary of data on chrysanthemum diseases and their control, including *Fusarium* wilt and stem rot, *Verticillium* wilt (with varietal relations), nematode root knot and leaf injury, powdery mildew, *Septoria* leaf spot, rust (with varietal relations), yellows, and ray blights.

A Phomopsis canker and gall disease of gardenia, G. A. HUBER (*Florists Exch. and Hort. Trade World, 86 (1936), No. 10, p. 11*).—In this study by the Western Washington Experiment Station, considerable damage by this disease in greenhouses is reported. A fungus of the *Phomopsis* type was readily isolated, and the disease is believed to be the same as that occurring in California and Ohio (E. S. R., 71, pp. 213, 662). The symptoms are described, and control measures are recommended.

Diseases of bulbous iris foliage described for growers, F. P. MCWHORTER (*Florists' Rev., 78 (1936), No. 2014, pp. 23, 24, figs. 2*).—This contribution by the Oregon Experiment Station discusses the identification and control of four of the commoner foliage diseases (not including the rusts), viz, the small- and large-spored *Heterosporium* leaf spots, *Epicoccum* blight, and *Mystrosporium* or ink spot.

Disease among the lilies, G. L. SLATE (*Horticulture, 14 (1936), No. 5, pp. 96, 97*).—This contribution by the New York State Experiment Station gives the author's experiences with mosaic and *Botrytis* blight, including control measures and species and varietal differences in susceptibility. A brief note on *Fusarium* basal rot is also included.

Spraying—pruning—die-back, H. R. ROSEN (*Amer. Rose Ann., 1935, pp. 43–47*).—This contribution from the Arkansas Experiment Station reports a continuation of spray experiments for the control of black spot and powdery mildew of roses (E. S. R., 73, p. 66), together with seasonal data on these diseases. It is concluded that, considering previous results, until a nonstaining copper acetate is shown to be an effective rose fungicide at a noninjurious con

centration Palustrex sulfonate B remains the most promising fungicide for the control of these two diseases in the Middle West and South. Combined with the wetting agent Aresco its covering power is excellent, and it leaves no objectionable deposit unless lead arsenate has been added.

From observational data, the author ventures the opinion that "die-back is frequently due to the slow starvation of a shoot caused either by an excessive removal of the food-making organs, the leaves, or by some adverse root condition." When most of the leaves of a shoot are destroyed or removed by pruning, etc., during the first half of the growing season, the roots depending on that shoot for elaborated foods fail to receive their necessary nutrients and starvation phenomena follow.

The 1934 disease-control campaign, L. M. MASSEY (*Amer. Rose Ann., 1935, pp. 48–52*).—This note from the [New York] Cornell Experiment Station refers to the campaign among rose growers for the control of black spot and mildew of roses.

Injury from spray materials, L. M. MASSEY (*Amer. Rose Ann., 1935, pp. 38–40, pl. 1*).—This note from the [New York] Cornell Experiment Station refers to the unusual spray injury to the leaves of roses during the summer of 1934.

Red copper oxide spray for black-spot, R. O. MAGIE and J. G. HORSFALL (*Amer. Rose Mag., 1 (1936), No. 21, pp. 5, 6*).—This contribution from the New York State Experiment Station reports successful control of black spot of roses by a spray containing 1 part of red copper oxide to 1,600 parts of water, carefully applied every 2 weeks. The addition of a cottonseed oil emulsion at every third application of this spray is recommended to avoid foliage injury. The common insecticides are stated to be compatible with this copper spray.

Control of black spot on roses studied at Cornell, L. M. MASSEY and E. W. LYLE (*Florists' Rev., 77 (1936), No. 1997, pp. 19, 20, 76, 77*).—This is a semipopular account of studies at Cornell University showing that black spot can be controlled in greenhouses by ceasing to syringe the plants, using Selocide for red spider control, and observing good greenhouse practices.

Control of black-spot on greenhouse roses, E. W. LYLE and L. M. MASSEY (*Florists Exch. and Hort. Trade World, 86 (1936), No. 9, pp. 11, 15*).—This is a progress report of studies by Cornell University showing that this disease may be controlled in greenhouses by avoidance of syringing and use of "Selocide" (1 part to from 300 to 400 parts of water) for red spider control. Other advantages from the elimination of syringing are enumerated.

A study of the life history of Ceratostomella ulmi in relation to the development and spread of the Dutch elm disease, C. MAY (*Ohio State Univ., Abs. Doctors' Diss., No. 17 (1935), pp. 271–276*).—This summary of a study of the Dutch elm disease, found for the first time in the United States in Ohio by the author in 1930, is a contribution by the Ohio State University. The work comprised an investigation of some of the factors affecting the isolation, growth, spore production, and identification of the organisms causing vascular wilt diseases of elms in this country; of certain phases of infection by *C. ulmi*, particularly infection courts and the histopathology of the disease as related to the movement and spread of the fungus in the wood; and of the spread of the disease in local infection centers in Ohio, New Jersey, and Indiana.

The Dutch elm disease situation, W. O. FILLEY (*Conn. Woodlands, 1 (1936), No. 1, pp. 11, 12*).—This is a note by the Connecticut [New Haven] Experiment Station.

A leaf-spot disease of honey locust caused by a new species of Linospora, J. H. MILLER and F. A. WOLF (*Mycologia, 28 (1936), No. 2, pp. 171–180, figs. 2*).—

As a result of this cooperative study between the University of Georgia and Duke University, *L. gleditsiae* n. sp. is described as the perfect stage of the fungus known under the conidial form as *Melasmia hypophylla*. The perithecial stage develops on overwintered leaves. The genetic connection of the two stages was indicated by the development of the conidial stage on leaves that had been inoculated, using leaves bearing the perithecia. Attempts to culture *L. gleditsiae* were unsuccessful.

Although included in the Clypeosphaeriaceae, the authors believe that *Linospora* preferably should be placed nearer the members of the Diaporthaceae.

Studies on the wood-rotting fungus Fomes pini.—I, Variations in morphology and growth habit, C. E. OWENS (*Amer. Jour. Bot., 23 (1936), No. 2, pp. 144–158, pls. 9*).—This study by the Oregon Experiment Station was made on sporophores collected from 6 genera and 21 species of coniferous trees, chiefly from Oregon and other parts of the Pacific Northwest. The sporophores varied greatly in form and size and in the shape and dimensions of the pores, not only as between those collected on different host genera and species but also among those from a single host species. Strictly annual sporophores were not observed, though this is at variance with published accounts in Europe and America recognizing a variety, *F. pini abietis*, said to have annual sporophores on fir, spruce, and larch. On living trees in the Pacific Northwest the sporophores occur at branch stubs or knotholes on all host species observed except on *Abies grandis*, where they occur gregariously in large numbers scattered over extensive, cankerlike areas of the bark. Detailed descriptions of the sporophores are given.

Use of calcium cyanamid in control of nematodes, H. DUKES and H. SHERARD (*Fla. Grower, 44 (1936), No. 5, pp. 7, 19, figs. 2*).—This study at the University of Florida was undertaken to determine the effects of applications of the granular form of calcium cyanamide on *Heterodera marioni* under both field and greenhouse conditions. With okra and tomatoes as index crops in two respective greenhouse tests, the treatment controlled the nematodes for from 8 to 12 weeks, and when the application was made 30 days before planting no ill effects on the crops were noted. In field tests with beans as the index crop the treatment also retarded the nematode development for a time.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Regulations relating to game, land fur animals, and birds in Alaska, 1936–37 (*U. S. Dept. Agr., Bur. Biol. Survey, Alaska Game Comm. Circ. 18 (1936), pp. 32, fig. 1*).—This is a summary of the Alaska game law and regulations. The complete text of the law has been given in Circular 10 (E. S. R., 70, p. 498).

Food of Arctic birds and mammals collected by the Bartlett expeditions of 1931, 1932, and 1933, C. COTTAM (*Jour. Wash. Acad. Sci., 26 (1936), No. 4, pp. 165–177*).—A summary is given of the food percentages by volume as determined from the analysis of stomachs, gullets, or crops of 115 birds representing 21 species and 1 additional subspecies collected on the three Arctic expeditions of R. A. Bartlett in the summers of 1931, 1932, and 1933. Reference is also made to the stomach contents of a weasel and 5 Hudson Bay ground squirrels collected.

Studies on the endoparasitic fauna of Trinidad mammals, II, III, T. W. M. CAMERON (*Canad. Jour. Res., 14 (1936), Nos. 1, Sect. D, pp. 1–5, figs. 11; 4, Sect. D, pp. 25–38, figs. 26*).—In the second report of studies (E. S. R., 74, p. 545), entitled Additional Parasites from Trinidad Deer, *Setaria bidontata*

(Molin) and *Eucyathostomum longesubulatum* Molin are recorded from the deer *Mazama simplicicornis* and are redescribed together with a species of *Oxyuris* from the same host. The third contribution, Some Parasites of Trinidad Carnivores, presents descriptions of two new species of cestodes, five of nematodes, two of Acanthocephala, and one linguatulid taken from carnivores in Trinidad.

[Contributions on entomological technic] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar., 1936, ET–79, pp. 3, pls. 2; ET–80, pp. 2, pls. 2; ET–81, pp. 3, pls. 2; ET–82, pp. 2; ET–83, pp. 2, pl. 1*).—Further contributions in this series (E. S. R., 75, p. 511) include the following: A Cage for Rearing Bark- and Wood-Boring Insects Under Field Conditions, by W. J. Buckhorn; An Inexpensive Constant-Temperature Oven, by R. A. Fulton; A Berlese Funnel for Collecting Smaller Soil Animals, by L. D. Christenson; A Method of Preparing Insect Specimens for Riker Mounts, by G. H. Kaloostian and H. C. Donohoe; and Apparatus for Placing Test Lots of Insects Within Parcels of Stored Tobacco During Fumigation Experiments, by W. D. Reed, E. M. Livingstone, and A. W. Morrill, Jr.

[Contributions on economic insects, insecticides, and insect control] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar., 1936, E–372, pp. 4, pls. 2; E–373, pp. 7; E–374, pp. 2; E–375, pp. 2; E–376, pp. 14; E–377, p. 1; E–378, pp. 13, pls. 2; E–379, pp. 3, pls. 2; E–380, pp. 6; E–381, pp. 74; E–382, pp. 4, pls. 2; E–383, pp. 4*).—Further contributions in this series (E. S. R., 75, p. 511) are: The Black European Slug [*Agriolimax agrestis* L.], a Pest of Tobacco Plants, by J. N. Tenhet and J. Milam; The Control of Flea Beetles [Tobacco Flea Beetle and the Potato Flea Beetle] Attacking Tobacco in the Southern Tobacco-Producing Regions, by J. U. Gilmore and F. S. Chamberlin; Present Status of Pea Aphid Control on Canning Peas, Its Possibilities and Limitations, by J. E. Dudley, Jr.; Suggestions on the Use of Derris Sprays for Control of the Pea Aphid and Recommendations for the Control of Insects Attacking Certain Vegetables, Small Fruits, and Tobacco, both by W. H. White; Results of Tests of Phenothiazine for Codling Moth Control, by B. A. Porter; Present Status of the Alfalfa Weevil Problem with Particular Reference to Quarantines, by P. N. Annand; The European Spruce Sawfly [*Diprion polytomum* Htg.], by H. J. MacAloney; A Report on Certain Dusts Tested Against the Citrus Thrips on Orange Trees, by E. A. McGregor; A Bibliography of Cyanide Compounds Used as Insecticides, 1932, by H. L. Cupples (E. S. R., 75, p. 511); Progress in Dried Fruit Insect Investigations in 1935, by P. Simmons, D. F. Barnes, H. C. Donohoe, and C. K. Fisher (E. S. R., 74, p. 227); and How the Bureau of Entomology and Plant Quarantine of the United States Department of Agriculture Affects You, by L. A. Strong.

[Notes on economic insects and insecticides] (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 629–634*).—Notes here presented (E. S. R., 75, p. 511) include the following: Comparison of Tetrahydronaphthalene and Ethylene Dichloride-Carbon Tetrachloride Mixture as Fumigants Against [Webbing] Clothes Moth Larvae, by W. Colman (pp. 629, 630); Efficiency of *Trichogramma minutum* Riley in Relation to Population Density of Its Host, by G. W. Barber (p. 631); Nitrogen Trichloride as a Fumigant, by R. S. Woglum and H. C. Lewis (pp. 631, 632); New Nymphal-Adult Parasite [*Aphelopus typhlocybae* Mueseb.] of White Apple Leafhopper, by H. M. Steiner (pp. 632, 633), contributed from the New York State Experiment Station; Enemies of the Mexican Mealybug (*Phenacoccus gossypii* T. & Ckll.), by W. E. Heming (p. 633); and Insects Infesting Cotton Seed, by T. L. Bissell (p. 634), contributed from the Georgia Experiment Station.

[Contributions on economic insects] (*Amer. Fruit Grower, 56 (1936), No. 2, pp. 9–11, 13, 14, 16, 26, 29, 31–33, 34, 35, 39, 42, 44, 45, figs. 12*).—Contributions

presented include Codling Moth Control: A Discussion, by L. Childs (pp. 9, 29, 33, 35), contributed from the Oregon Experiment Station; Outsmart Codling Moth: Cut Infestations in Half by Orchard Sanitation, by D. L. Van Dine (pp. 10, 32, 39); Controlling Citrus Insect Pests in California, by R. H. Smith (pp. 11, 45), contributed from the California Citrus Experiment Station; Winning the Fight Against Apple Flea Weevil, by J. S. Houser (pp. 13, 26, 34), contributed from the Ohio Experiment Station; Hand Syringe to Modern Power Sprayers: The History of Nicotine Sprays, by J. Howard (pp. 14, 42); and Spray Service by Wire and Air, by W. H. Zipf (pp. 16, 31, 44).

[Contributions on economic entomology] (*Ztschr. Angew. Ent., 22 (1935), Nos. 1, pp. 1–160, figs. 46; 2, pp. 165–330, figs. 59; 3, pp. 331–513, figs. 49; 22 (1936), No. 4, pp. 521–652, figs. 36*).—The contributions presented (E. S. R., 73, p. 644) are as follows:

No. 1.—The Egg Development of the Mediterranean Flour Moth at Constant and Fluctuating Temperatures, I, by A. D. Voûte (pp. 1–25); Observations on the Biology of *Bruchus obtectus* Say, With Special Reference to the Nutritional Factors, by G. M. Herford (pp. 26–50) (in English); The Selection System in Cockchafer-Infested Forests, by Puster (pp. 51–60); The Life History, Economic Importance, and Control of *Cerambyx cerdo* L., by D. F. Rudnew (pp. 61–96); The Causes of Hibernation of the Gypsy Moth, the nun moth, and Other Lymantriids in the Egg Stage, by K. Tuleschkov (pp. 97–117); Contribution to the Control of the Cabbage Maggot (*Phorbia brassicae* Bouché) by Sprays and Dusts, by H. Gasow (pp. 118–130); The Distribution of Tabanidae in the Dutch East Indies and Its Economic Importance, by O. Nieschulz (pp. 131–142); The Organization of the Entomological Service in Canada, by K. E. Schedl (pp. 143–156); and The Bark Beetles and Their Host Plants (Remarks and Supplements to Kleine's Paper of the Same Title (E. S. R., 73, p. 644)), by A. Pfeffer (pp. 157–160).

No. 2.—The Egg Development of the Mediterranean Flour Moth at Constant and Fluctuating Temperatures, II, by A. D. Voûte (pp. 165–184) (see above); The Leaf-Cutting Ant *Atta sexdens* L., Particularly Its Ecology, I, by H. Eidmann (pp. 185–241); A Contribution to the Question of Races in *Culex pipiens*, by A. de Buck (pp. 242–252); Contributions to the Natural History of Sawflies, by C. S. Hsin (pp. 253–294); and The Control of Animal Pests of Asparagus, by M. Dingler (pp. 295–330).

No. 3.—Physiological Investigations of the Action of Ecological Factors, Particularly Temperature and Humidity, on the Development of *Diprion (Lophyrus) pini* L. in Determining the Causes of Variation in Abundance, by K. Gösswald (pp. 331–384); Knowledge of the Leaf-Cutting Ant *Atta sexdens* L., Particularly Its Ecology, II, by H. Eidmann (pp. 385–436) (see above); The Sensitivity of the Leaf-Cutting Ant *Atta sexdens* L. to Poisonous Gases, by H. Schmalfuss (pp. 437–451); The Question of the Vital Optimum Temperature—V, The Relation in Insects of the Speed of Development to the Vital Optimum, by I. W. Kozhantschikow (pp. 452–462) (E. S. R., 72, p. 217); The Beet Root Weevil *Bothynoderes punctiventris* Germ. in Turkey, by F. Eckstein (pp. 463–507); and A Contribution to the Study of the Death of Elms in Czechoslovakia (pp. 508, 509), The Two Spruce Nest Worms *Epiblema tedella* Cl. and *E. proximana* Hw. (pp. 510, 511), and Parasite Rearing by the Government Forest Protection Experiment Station in Praha (Prague) (pp. 511–513), all by K. E[scherich].

No. 4.—The Development of the Pine Sphingid *Sphinx pinastri* L. as Affected by Temperature and Humidity, by K. Gösswald (pp. 521–532); The Temperature Dependence of the Nun Moth *Lymantria monacha* L. (Vital Zone,

etc.), by F. v. Arnim (pp. 532–557); Results of Parasite Rearings (pp. 558–564) and The Outbreak of the Fir Shoot Tortricid (*Cacoecia murinana* Hübn. in Niederösterreich (Lower Austria) in 1929–34 (pp. 565–602), both by E. Schimitschek; Experimental Control of the Granary Weevil With Dust Insecticides, by B. Germar (pp. 603–630); *Syntomaspis eurytomae* n. sp., a Chalcid With a Mixed Diet in the Larval Stage, by E. W. Puzanova-Malysheva (pp. 631–642); and The Black Spruce Bark Beetle *Hylastes cunicularius* Er., by K. Eckstein (pp. 643–652).

Connecticut State entomologist, thirty-fifth report, 1935, W. E. Britton (*Connecticut [New Haven] Sta. Bul. 383 (1936), pp. 245–366+XI–XVI, figs. 29*).—Entomological features of 1935 (pp. 249–251) (E. S. R., 73, p. 641); insect record for 1935 (pp. 252–267); inspection of nurseries, 1935, by Britton and M. P. Zappe (pp. 269–278), and of apiaries, by Britton (pp. 279–285); report of control of the gypsy moth, by Britton, J. T. Ashworth, and O. B. Cooke (pp. 285–291), present status of mosquito control work in Connecticut, by R. C. Botsford (pp. 292–301); European corn borer control, by Britton, Zappe, and N. Turner (pp. 301–303); and Japanese beetle work in Connecticut, by J. P. Johnson (pp. 304, 305), are first presented. Then follow reports on tests of apple sprays, by Zappe and E. M. Stoddard (pp. 305–308); the European spruce sawfly *Diprion polytomum* Htg. in Connecticut, where it was first found in October 1934 (pp. 308–312), and notes on a scale insect new to Connecticut, *Matsucoccus matsumurae* Kuwana (p. 313), both by G. H. Plumb; white grub (*Phyllophaga fusca* Froh.) injury to seedling apple and pear trees (pp. 313–315), studies in breeding and control of the apple maggot (pp. 315–320) (see p. 671), continued study of arsenical burn on peach trees (pp. 320–322), further notes on spray residues for 1935 (pp. 322–324), continued tests with substitutes for lead arsenate (p. 324), and report on parasite work for 1935 (pp. 325, 326), all by P. Garman; clusters of flies (*Atherix variegata* Walk.) mistaken for rust patches, by Britton (pp. 326, 327); notes on the hairy chinch bug *Blissus leucopterus hirtus*, a pest of lawns, by B. H. Walden (pp. 328, 329); further infestations of *Calomycterus setarius* Roelofs, by Zappe (pp. 329, 330); note on *Tetralopha robustella* Zell. in Connecticut (Pyralidae, Lepidoptera), by Plumb (pp. 331–333); further observations on the squash bug in Connecticut, by R. L. Beard (pp. 333–339); further observations on termite (*Reticulitermes flavipes* Kollar) damage, by Turner and Zappe (pp. 340, 341); the relation between the hibernating female and the survival of the spring generation of the spruce gall aphid *Adelges abietis* L., by R. B. Friend (pp. 341–344); cooperative European corn borer egg parasitism investigation, by J. C. Schread (pp. 344–346), and conditioning a basement room for breeding insects, by J. F. Townsend (pp. 346–350).

The report concludes with miscellaneous insect notes (pp. 350–362), including the black widow spider *Latrodectus mactans* Fab., damage by the strawberry weevil, an outbreak of Say's blister beetle, the bagworm in New Haven, a borer in cattail (*Nonagria oblonga* Gr.), a leaf miner of chrysanthemum (*Agromyza maculosa* Malloch), the abundance of a white geometrid moth (*Physostegania pustulata* Guen.) and of the elm lacebug *Corythucha ulmi* Osb. & Dr., injury to rhododendron seedlings by *Oniscus asellus* L., structural wood injured by powder-post beetles (*Lyctus* sp.), the forest tent caterpillar, elm spanworm, prevalence of the fall cankerworm, lime tree looper, elm leaf aphid *Myzocallis ulmifolii* Monell, control of rosy apple aphids with California ladybeetles (convergent ladybeetle), plant bug (*Lygus* spp.) injury to fruit, abundance of eastern tent caterpillar, a leaf tier (*Plutella porrectella* L.) of sweet rocket, worms (European corn borer) in cake, injury to vegetables by the

garden millepede *Julus hortensis* Wood, the house centipede, the fruit tree leaf roller, and the black carpenter ant.

[Report of work with insect pests and rodents by the Florida Station] (*Florida Sta. Rpt. 1935, pp. 64, 65–69, 84, 100, 109–112, 115, 116, figs. 2*).—The work of the year with insect pests and rodents and their control (E. S. R., 73, p. 204) referred to includes the Florida flower thrips *Frankliniella cephalica bispinosa* Morg., by J. R. Watson; the introduction and propagation of beneficial insects (*Leis dimidiata* var. *15-spilota* Hope), by Watson and W. L. Thompson; the larger plant bugs (leaf-footed bugs, *Acanthocephalus fermorata*, *A. confraterna*, and the southern green stinkbug), by H. E. Bratley; potato leafhopper investigations, by A. N. Tissot; the green citrus aphid *Aphis spiraecola* Patch, by Watson and Thompson; the pecan nut casebearer, by Watson and G. B. Fairchild; the onion thrips, by Watson; the gladiolus thrips, by Watson and J. W. Wilson; biology and control of Florida aphids, by A. N. Tissot; an electrical method for determining concentration of hydrocyanic acid gas in air mixtures, by R. J. Wilmot; control of the purple scale and white flies with lime-sulfur at the Citrus Substation, by Thompson; and miscellaneous insect pests and their control, the prevalence and control of the sugarcane borer in south Florida, and the prevalence and control of rodents under field and village conditions, all by R. N. Lobdell at the Everglades Substation.

[Report of work in entomology by the Idaho Station] (*Idaho Sta. Bul. 220 (1936), pp. 30–34, fig. 1*).—The work with economic insects referred to includes beet leafhopper control, biological control of fruit insects, unsuccessful eradication of the cherry fruitfly, effective use of cube kaolin dust against several insects, grasshopper control, introduction of the European earwig parasite *Digonichaeta setipennis* Fall., physiological studies of the effect of poisons on insects, ladybeetle predators for the pea aphid, increased resistance by certain onion varieties to onion thrips, favorable hibernation important to the pea weevil *Triaspis thoracicus* Curt., spray combinations and codling moth control, control of the European elm scale by summer sprays, and increase of wireworms in red clover or sweetclover fields.

[Report of work in entomology by the Michigan Station], R. HUTSON (*Michigan Sta. Rpt. 1935, pp. 218, 219*).—Brief reference is made to the work of the year (E. S. R., 73, p. 505) with zinc arsenate for control of codling moth, the control of the tarnished plant bug, aphids, and cutworms, and observations on grasshoppers.

[Report of work in economic entomology by the Montana Station] (*Montana Sta. Rpt. 1934, pp. 36–40*).—The work of the year with insects and insect control is briefly referred to, including insecticides, identification of insects, and prediction of grasshopper outbreaks.

[Work in economic entomology and zoology by the New Jersey Stations] (*New Jersey Stas. Rpt. 1935, pp. 18–20, 38–46*).—This report (E. S. R., 73, pp. 203, 205) refers to work on the biology of the oyster; mosquito investigations and control; the effect of low frequency alternating current upon Japanese beetle grubs and earthworms in soils; the effect of high frequency electric current on bacteria; the effect of infrared oscillation on insects and their food; investigations of codling moth, leopard moth, spray injury, derris, cube root, *Cracca virginiana*, anabasine sulfate, and a large number of other new insecticides involving organic and inorganic chemicals, new wetting agents to be used in place of soap, nicotine fumigation for control of mushroom flies, paradichlorobenzene for control of wireworms, and control of strawberry rootworm and boring insects in trees and shrubs; and bee investigations.

[Report of work in economic zoology by the South Dakota Station], H. S. SEVERIN (*South Dakota Sta. Rpt. 1935, pp. 26–30*).—The work of the year

referred to (E. S. R., 73, p. 205) includes that on the economic importance, distribution, life history, and control of cyrtacanthacrine grasshoppers; insects as pollination agents of sweetclover; and the economic importance of blister beetles.

Effect of orchard practices on codling moth and leafhopper parasitism, B. F. DRIGGERS and B. B. PEPPLE (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 477–480*).—At the New Jersey Experiment Stations codling moth eggs exposed for 3 days showed low parasitism by *Trichogramma* sp. in a heavily sprayed orchard and high parasitism in an unsprayed orchard. Larval and pupal collections in late summer in three orchards showed more parasitism in a heavily sprayed and weedy orchard than in a heavily sprayed and clean-cultivated orchard and four and one-half times as much larval parasitism in an unsprayed and uncultivated orchard.

"Three plats of apple trees receiving different spray treatments following petal fall varied in leafhopper [mostly apple leafhopper] population and the percentage of leafhopper parasitism. Low leafhopper parasitism was correlated with high leafhopper populations. The highest percentage of parasitism and the lowest leafhopper population was found on the plat receiving no spray treatment following petal fall. The plat sprayed with lead arsenate-oil for first brood and nicotine tannate for second brood, while not as high in parasitism as the plat unsprayed following petal fall, showed one-sixth the population and 14 times the parasitism found on the plat sprayed with lead arsenate-oil during first and second brood."

Feeding and utilization of sucrose solutions by potato flea beetle and fall webworm: Feeding insecticides to flea beetle, D. O. WOLFENBARGER (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 586–589, figs. 2*).—A discussion is given of a method of feeding insects with biting mouth parts that has been employed with success. The potato flea beetle lived considerably longer on sucrose solution than water alone, and longer on water than in the starvation check. Barium fluosilicate was the most toxic of the inorganic poison materials tested. Beetles sprayed and dusted with bordeaux mixtures, alone and in combinations with some common stomach poisons, lived almost as long as those in the water check. Beetles sprayed with 5–5–50 bordeaux combined with calcium arsenate, however, did not live as long as those in the water check.

Reference is also made to the maintenance of life of fall webworm larvae by consumption of a 20 percent sucrose solution.

Determination of the less refined mineral oils on leaf surfaces after spraying, L. H. DAWSEY (*Jour. Agr. Res. [U. S.], 52 (1936), No. 9, pp. 681–690, fig. 1*).—This further study (E. S. R., 60, p. 12) reports upon the determination of the less refined petroleum oils in the presence of materials extracted from plant foliage by ethyl ether.

"Treatment of the leaf extract residues containing petroleum with nitric acid under controlled conditions results in destruction of a definite proportion of the oil each time, and by using a predetermined correction factor the original quantity of the oil present can be estimated. Applications are suggested in the determination of oil deposit from the foliage of camphor-tree, Satsuma orange, and chrysanthemum plants following spraying with oil emulsions. The method of analysis of these sulfonatable oils in the presence of chrysanthemum leaf materials has been simplified, without loss of accuracy, by omitting the usual wax-freezing step as employed in the treatment of the camphor-tree and Satsuma orange leaf extracts. The efficiency in oil recovery in washing leaf disks taken from sprayed plants with ethyl ether has also been studied. For a limited number of washings recovery is not complete, but from 90

to 95 percent of the oil is removed even when extraction is made 24 hr. after the spray application.

"The work of other investigators is discussed in the light of the present work, and the position taken that the total oil deposit is the preferable quantity to measure in the study of the insecticidal action of oils."

A list is given of eight references to the literature cited.

An account of the constitution and use of an atomised white oil, pyrethrum fluid, to control Plodia interpunctella Hb. and Ephestia elutella Hb. in warehouses, C. POTTER (*Ann. Appl. Biol., 22 (1935), No. 4, pp. 769–805, pls. 3, figs. 4*).—Following a brief account of the life history of the tobacco moth and the Indian meal moth in London warehouses, an account is given of a pyrethrum fluid insecticide, the technic of application, and the results of tests of its value in combating the infestation of imported stored products in warehouses. A list of 29 references to the literature is included.

Insect damage to seeds of Cracca virginiana L., J. S. YIP (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 622–629, figs. 2*).—In the course of an investigation of *C. virginiana*, a native North American perennial leguminous weed occurring from Canada to Florida, Texas, and Mexico, with regard to its possibilities as an insecticide, the seed was found to be widely damaged by insects, the more common of which are *Apion scgnipes* Say, the bean weevil, and *Ulophora tephrosiella* Dyar. The number of parasites of these pests is very low. Information thus far obtained shows that the larvae of *A. segnipes* and *U. tephrosiella* do much damage to the seed, and that little damage is caused by the bean weevil.

Stickers for derris applied as an insecticide spray, L. D. GOODHUE and W. E. FLEMING (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 580–583*).—In laboratory work aimed at the development of a suitable sticker for derris when used as an insecticide spray for control of the Japanese beetle, several oils, waxes, resins, agar-agar, and other materials were tested on glass plates and the most promising then tested on bean foliage. Rosin residue, the residual material left in the still during the manufacture of rosin, when emulsified with ammonium caseinate was found to be the most satisfactory and inexpensive sticker for derris.

The toxic effects of naphthalene on Bruchus obtectus and Tenebrio molitor in various stages of development, L. PYENSON and G. F. MACLEOD (*Jour. Agr. Res. [U. S.], 52 (1936), No. 9, pp. 705–713, figs. 2*).—A study of the toxicity of naphthalene to the bean weevil and the yellow mealworm in their various stages of development, conducted by the [New York] Cornell Experiment Station in cooperation with the Instituto de Pesquizas Agronomicas, Pernambuco, Brazil, is reported.

In experimental work with eggs of the two insects the toxicity of the naphthalene was found to vary with the age of the eggs. The rate of respiratory metabolism of the eggs measured by the percentage of daily loss in weight was directly related to lethal dosages of naphthalene. "An increased loss in weight was associated with a greater toxicity of naphthalene to the eggs. The development of bean weevil eggs was noticeably retarded by sublethal exposure to naphthalene vapor. The developmental rate of mealworm eggs was not significantly affected by sublethal exposures to naphthalene. Eggs and very young larvae of the mealworm when fumigated with naphthalene turned reddish brown, the color intensity varying directly with the period of exposure.

"Experiments with larvae of the mealworm showed that the toxicity of naphthalene decreased with increased age and weight of the larvae. Sublethal exposures of mealworm eggs or young larvae to naphthalene did not affect subsequent growth.

"Resistance to naphthalene varied greatly between instars of the more advanced stages of the mealworm. The order of susceptibility of all the stages of the mealworm to naphthalene from least to greatest resistance was: (1) Eggs, (2) young larvae, (3) adults, (4) prepupae, (5) pupae, [and] (6) mature larvae. Increased respiratory metabolism as measured by percentage daily loss in weight appeared to be related to increased toxicity of naphthalene with the different stages of the mealworm.

"In experiments with several species of adult insects and closely related organisms, Diptera were most susceptible to naphthalene while Coleoptera were most resistant.

"Injections of olive oil solutions of naphthalene into mealworm pupae produced the same toxic effects as when the pupae were exposed to naphthalene vapor. Naphthalene was a slow-acting poison to the pupae even when injected into the body. The nervous and muscular systems were not the first tissues to be affected, as shown by the wriggling movements of the darkened, dying pupae when touched. Fat bodies were probably the first tissues to be affected, since they appeared to be partly disintegrated and discolored in treated larvae and pupae."

Persistence of toxicity of nicotine-bentonite on apples, W. MOORE (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 590–594*).—In the experiments reported the toxicity of nicotine-bentonite was not destroyed by sunlight. The persistence of its toxicity on apples compared favorably with that of arsenate of lead-lime-milk.

Constituents of pyrethrum flowers.—II, Isolation of pyrethrin II, F. B. LAFORGE and H. L. HALLER (*Jour. Amer. Chem. Soc., 57 (1935), No. 10, pp. 1893–1896*).—Reporting further (E. S. R., 75, p. 160), a procedure for the preparation of pyrethrin II is described. "Petroleum ether extractives of pyrethrum flowers are separated from fats and waxes by the employment of acetic acid. The acids are removed from the concentrate by extraction in aniline solution with potassium carbonate. Partial separation of pyrethrin II from pyrethrin I is accomplished by taking advantage of their different solubilities in a system consisting of diluted acetic acid and petroleum ether. Pyrethrin II tends to concentrate in the acid solution, pyrethrin I in the petroleum ether. Concentrates so obtained containing about 80 percent of pyrethrin II and about 6 percent of pyrethrin I are distilled in a molecular still and yield pure pyrethrin II."

Constituents of pyrethrum flowers.—III, The pyrethrin content of fresh flowers, F. ACREE, JR., P. S. SCHAFFER, and H. L. HALLER (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 601–605*).—A study was made of pyrethrum flowers (see above) to determine if the pyrethrins are present in the fresh flowers, and if so, to what extent they are affected by enzyme activity and moisture content in the process of drying. The finding by Gnadinger et al. (E. S. R., 70, p. 53) that the method of drying produces very little variation in the pyrethrin content is confirmed. It is shown that the pyrethrin I and pyrethrin II exist as such in the fresh pyrethrum flowers. Enzymes and moisture have a negligible effect on the synthesis or decomposition of the pyrethrins in the process of drying the flowers.

Pyrethrin content of pyrethrum flowers from various sources, D. G. HOYER and M. D. LEONARD (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 605, 606*).—The results of an assay of the toxic value of prethrum flowers from various sources, in which 5-day-old houseflies were used and the sprays were prepared by extracting the ground flowers with kerosene at the rate of 1 lb. per gallon, are reported.

Insecticidal activity of aliphatic thiocyanates.—III, Red spiders and mites, D. F. MURPHY (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 606–611*).—Laboratory and field tests here reported (E. S. R., 70, p. 208) have demonstrated that B butoxy B′ thiocyanodiethylether at 1 : 800 when properly emulsified and used with a spreader successfully controls the common red spider. Tests conducted under field conditions on the European red mite on apples indicate that B butoxy B′ thiocyanodiethylether at 1:2,400 when properly emulsified and used with a spreader gives good control. The thiocyanate may be used with lime-sulfur or flotation sulfur to make a combination contact insecticide and fungicide. Preliminary tests indicate that the thiocyanate at 1:800 will destroy about 70 percent of the eggs of the red spider. Further work must be done on this phase of the problem.

Relative toxicity at high percentages of insect mortality, H. H. SHEPARD (*Nature [London], 134 (1934), No. 3383, pp. 323, 324, figs. 2*).—In this contribution from the Minnesota Experiment Station it is pointed out that estimates of the relative toxicity of insecticides have been made largely on the basis of amounts required to kill only half of an insect population. Mathematical considerations prevent high precision in determining the lowest amount to kill an entire population. An easy method is given in this paper by which good approximations of high percentages of mortality may be calculated from certain predetermined points on the toxicity curve.

Studies of seasonal occurrence of injuries to potato tubers in western New York, F. G. BUTCHER (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 486–490, figs. 2*).—Investigations of scab, scab gnat, and millepede injuries to potato tubers conducted in Monroe County, N. Y., in the past 4 yr. are considered, the results being presented in table and graph form. The scab gnat injuries appeared to follow scab infection, but since the proportion of injured tubers remained constant during the middle of the season and later actually decreased, it was apparent that millepedes also feed on the portions of the tubers injured by scab gnats.

A contribution to the knowledge of sugar-beet insects in Ontario, G. M. STIBBETT (*Sci. Agr., 16 (1935), No. 4, pp. 180–196*).—Following a brief reference to the importance and history of sugar beet production in Ontario, this contribution presents a historical review of and incidental notes on sugar beet insects in Ontario; results of regular collections of insects from sugar beet fields, of which the details are presented in two tables; collections from various fields in Chatham district; beneficial insects of sugar beet fields; an annotated catalog of invertebrates associated with the beet plant in Ontario; and a list of 36 references to the literature.

The effect of the freeze of December 12 and 13 on citrus pests in Florida, W. W. YOTHERS and M. R. OSBURN (*Fla. State Hort. Soc. Proc., 48 (1935), pp. 122–126*).—The results of observations of the effect on important citrus insects of the freeze of December 12 and 13, 1934, when the temperature fell to 22° F., are reported, the details being given in tables. Similar studies were conducted in 1917 (E. S. R., 43, p. 554).

The data indicate that the direct effect of the freeze on the citrus white fly pupae, which insect occurs as far north as North Carolina, amounted to very little, it being doubtful if the cold killed any pupae other than those deprived of normal food supply by defoliation. The purple scale is much more resistant to the low temperature of 22° than the Florida red scale. Examination made of the respective species in the same grove showed that 71.7 percent of the purple scales and only 28.5 percent of the red scales survived. The low temperatures actually froze some rust mites, but great numbers were

also left and were present on completely frozen fruit immediately after the freeze. After the freeze several living specimens of *Tenuipalpus irritans* and *Tetranychus citri* were found, and it is very doubtful if very many of these were frozen. While papaya plants in central Florida were killed to the level of the ground by the freeze, a large percentage of the larvae of the papaya fruitfly in the fallen fruit survived. The observations indicate that little or no mortality of the rust mite is caused by the sulfur dust during low temperatures.

Studies conducted by Watson during this period have been noted (E. S. R., 73, p. 348).

The trend of citrus insect control in Florida, J. R. WATSON (*Fla. State Hort. Soc. Proc., 48 (1935), pp. 91–93*).—This discussion is contributed from the Florida Experiment Station.

The control of purple scale and rust mites with lime-sulfur solution, W. L. THOMPSON (*Fla. State Hort. Soc. Proc., 48 (1935), pp. 98–107*).—This is a practical contribution from the Florida Experiment Station, based upon investigations a detailed report of which has been noted (E. S. R., 74, p. 230).

Shade-tree insect developments, E. P. FELT and S. W. BROMLEY (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 490–492*).—A discussion of important shade tree insect developments in 1935 (E. S. R., 73, p. 348).

Fumigation of flour mills with hydrocyanic acid gas, R. T. COTTON, H. D. YOUNG, and G. B. WAGNER (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 514–523, figs. 4*).—Data on the efficiency of fumigation with hydrocyanic acid gas as affected by the methods of producing and applying the gas, the type of construction of the building, the preparation of the mill, wind velocity, etc., observed in many mill fumigations in the middle western United States and extending over a period of two seasons are reported upon. Observations were made as to the relative cost and as to the efficiency of the fumigations in terms of insects killed and in gas concentrations obtained. The details are given in three tables and a number of graphs.

Killing insects in empty grain bins, H. H. SHEPARD (*Grain and Feed Journs. Cons., 73 (1934), No. 12, p. 511; abs. in Minnesota Sta. Rpt. 1935, p. 46*).—Attention is called to the misuse of contact insecticides for the control of grain insects and the importance of distinguishing between contact insecticides and insect fumigants. The use of kerosene as a contact insecticide is discussed with particular reference to its inflammability.

Possible insect carriers in the 1933 outbreak of encephalitis in Columbia, Mo., L. HASEMAN (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 618–621*).—In reporting upon a study made by the Missouri Experiment Station of an outbreak of encephalitis at Columbia, Mo., in 1933, which followed a much heavier epidemic in St. Louis and vicinity, three groups of insects are said to have been found outstanding at the beginning of or throughout the epidemic, namely, mosquitoes, leafhoppers, and the large bluebottle or blowflies (*Cynomyia cadaverina* R. D., *Calliphora erythrocephala* Meig., and *Phormia regina* Meig.).

The significance of the dragonfly name "Odonata", C. E. MICKEL (*Ann. Ent. Soc. Amer., 27 (1934), No. 3, pp. 411–414; abs. in Minnesota Sta. Rpt. 1935, p. 16*).—This contribution discusses the derivation and meaning of the dragonfly ordinal name Odonata.

Effect of thrips on pollination and blossom blight in strawberries, M. D. FARRAR (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 483–486, fig. 1*).—The flower thrips drifting into strawberry beds in Illinois cause a rapid increase in population during the early bloom; during the height of the bloom the numbers per bloom decrease, but again increase rapidly late in the season when few blooms are present. Both laboratory and field experiments indicate that the so-

called blight which they cause occurs on infested and weak blooms, the stronger blooms pollinating and producing fruit irrespective of thrips populations. They have been found to be only a minor limiting factor in the pollination and the production of fruit under field conditions.

Notes on the louse problem of a municipal workhouse, M. J. OOSTHUIZEN and H. H. SHEPARD (*Jour. Parasitol., 21 (1935), No. 4, pp. 318, 319; abs. in Minnesota Sta. Rpt. 1935, p. 44*).—The results of daily examinations of transients at the Minneapolis workhouse for lice infestation over a period of 20 mo. are briefly reported. During that period 7,818 men were examined, of whom 23.8 percent were found infested.

Parasitism of the apple leaf hopper (Typhlocyba pomaria) by Entomophthora, S. A. WINGARD (*Phytopathology, 26 (1936), No. 2, p. 113*).—Brief reference is made to the finding that the white apple leafhopper in Virginia apple orchards was destroyed by the fungus parasite *E. sphaerosperma* following an almost continuous rainfall the first week of September 1935, which prevented the application of sprays.

Biological control of the sugar cane leafhopper in Hawaii, O. H. SWEZEY (*Hawaii. Sugar Planters' Sta., Ent. Ser. Bul. 21 (1936), pp. [2]+57–101, figs. 29; also in Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 40 (1936), No. 1, pp. 57–101, figs. 29*).—The introductory part of this contribution takes up the early history of leafhoppers in Hawaii, plans for importation of parasites, and the organization and details of the work.

An account is then given of the parasites introduced, eight in number, namely: *Paranagrus optabilis, P. perforator, Anagrus frequens, Ootetrastichus beatus, O. formosanus, Haplogonatopus vitiensis, Pseudogonatopus hospes,* and *Cyrtorhinus mundulus.* The natural enemies that were already present in Hawaii, some 20 in number in addition to spiders, and the enemies of spiders are then considered.

A brief reference is made to fungus diseases of the leafhopper. A list is given of the literature cited and bibliography, together with an appendix dealing with the distribution of 23 leafhoppers of the genus *Perkinsiella,* chiefly sugarcane-infesting forms.

Experiments with derris as a control for the pea aphid, J. E. DUDLEY, JR., T. E. BRONSON, and F. E. CARROLL (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 501–508*).—Greenhouse experiments with the pea aphid demonstrated that ground derris, applied as a spray at the rate of from 0.25 to 5 lb. per 100 gal. (0.0009 to 0.022 percent of rotenone) with a spreader and wetting agent, killed more than 90 percent of the aphids on the treated plants. The aphids died during a period of from 3 to 5 days, and practically no reproduction occurred in the interim.

"A large number of tests on late-planted peas revealed that derris as a spray, with a spreader and wetting agent, applied prior to aphid infestation, protected the plants from appreciable damage for several weeks and resulted in an ultimate infestation considerably lower than had developed in the untreated checks; that heavy applications of derris sprays after the incidence of an infestation protected peas from damage from a commercial standpoint for nearly a month, enabling them to produce a normal crop of pods; that heavy applications of derris sprays with any one of several spreaders and wetting agents, made after the infestation had become heavy, killed approximately 95 percent of the aphids; that derris sprays controlled the aphid more quickly and to a higher degree than did derris dusts; and that concentrations of derris as low as 0.25 to 0.5 lb. (0.0009 to 0.0019 percent rotenone) per 100 gal., with spreaders and wetting agents, killed approximately as large a percentage of aphids as did 8 lb. per 100 gal.

"On the basis of the experiments reported herein, it appears that sprays of ground derris root containing 0.0044 percent rotenone, or possibly lesser concentrations, with a spreader and wetting agent, applied to pea vines while aphids are present in small numbers, give promise of effective control of the pea aphid."

Tar-oil and lubricating-oil sprays in relation to rosy aphid control and to winter-injured trees, F. Z. HARTZELL (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 556–561, fig. 1*).—This contribution from the New York State Experiment Station presents the results of a series of tests with tar oil and lubricating oil sprays applied in the spring of 1935 to determine their relative insecticidal efficiencies on the rosy apple aphid and their effects on apple trees which had a single growth period following a severe winter. An earlier account by the author et al. of the climatic conditions in western New York in 1933 and 1934 and the effects on fruit trees has been noted (E. S. R., 73, p. 342).

A concentration of 2.4 percent of creosote oil appears to be a practical amount to secure a high degree of control. In a tar-lubricating oil spray the toxic effects on aphid eggs apparently depend entirely upon the concentration of creosote oil and are not increased by the lubricating oil present, at least when the latter does not exceed 3 percent. The similar results secured, at the same dilutions of creosote oil, with all commercial brands and with tank-mixed emulsions, indicate that either all the manufacturers have used creosote oil which meets the standards proposed in 1934 or that the differences are not sufficient to affect the control of the aphid.

Cresylic acid in lubricating oil applied during the early green-tip stage gave more variable control than did creosote oil. Similar results have been secured in more extended tests during the past 6 yr. Notwithstanding its defects, cresylic acid and lubricating oil may have a place in the spray program

"Nicotine sulfate, 1:800 in 3 percent lubricating oil, applied during the green-tip stage, gave results similar to cresylic acid and oil. When used at a concentration of 1:400 excellent control was obtained. These results are similar to those secured in more extensive field tests during the past 4 yr. and indicate that these mixtures may help to extend the period for rosy aphid control."

In 1934 a number of trees were sprayed with creosote oil, lubricating oil, or a combination of both oils, and considerable twig injury resulted where the concentrations were in excess of 3 percent. Since no twig injury occurred in 1935, at similar concentrations, apparently the trees tolerated heavier dosages in 1935 than in 1934.

Apparently creosote oil and lubricating oil, when either was used alone, were quite similar in their effects on set of fruit. Water-gas tar oil appears to have been less toxic to the fruit buds than creosote oil when both were used at the same concentration.

A graph is given which shows the stages of the apple buds during periods when the several mixtures for the rosy apple aphid, eye-spotted budmoth, and San Jose scale should be applied and the average dates during the past 5 yr. when these conditions were found at Geneva, N. Y.

Comstock's mealybug as an apple pest, A. M. WOODSIDE (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 544–546*).—An outbreak of *Pseudococcus comstocki* Kuw. occurred in apple orchards in a restricted area of Albemarle County, Va., in 1934, and caused heavy losses. A dormant spray containing 4 percent of tar oil and 2 percent of petroleum oil applied after the trees had been scraped thoroughly and the larger masses of eggs removed gave good control. Nicotine sprays applied during the period of the first two cover sprays were also effective. Late summer applications for the second brood were not satisfactory

because many of the insects were within the calyxes, where they could not be reached.

Effect of oil spray on California red scale at various stages of development, W. EBELING (*Hilgardia [California Sta.], 10 (1936), No. 4, pp. 95–125, figs. 11*).—Experiments were made with a view to determining (1) the extent to which the settling of California red scale crawlers is inhibited by oils of various degrees of heaviness and sprays at different concentrations, and (2) the effect of oil sprays on both immature and adult stages.

Experimental data presented confirm the preliminary observation that the ultimate effect of oil spray on a red scale population is also influenced by the inhibition of the settling of crawlers for some time after the oil spray is applied. The data obtained indicate that where the normal amount of oil is deposited in the application of oil spray under orchard conditions there is a great reduction, for at least a month after the spray is applied, in the percentage of crawlers able to settle on the foliage. Among the crawlers able to settle and form whitecaps during this interim, there is a greater mortality than where oil spray has not been applied.

Attempts at control of the red scale with dusts directed against the crawlers have been unsuccessful because of practical considerations. All immature stages of the red scale are more easily killed by oil spray than the mature adult, probably because they are not as thoroughly sealed to the substratum upon which they rest and because their spiracles are not as far from their margins; they are thus more accessible to the oil.

"The majority of adult scales are killed by tracheal penetration of the oil, although, at least on the bark, a large percentge of them die from an oil spray treatment without tracheal penetration. Adult red scales with their margins loosened or lifted from their substratum are more vulnerable to oil sprays than are those not treated in this manner. It has been demonstrated that oil penetrates through the armor of the red scale. The armors of adult scales were painted with oil, care being taken that no oil should enter beneath the bodies of the insects. In two experiments, 5.64 and 17.78 percent of the insects treated in this manner were killed by the treatment in 16 days and 44 days, respectively. Those alive at the end of 2 weeks gave birth to a certain percentage of dead embryos and dead crawlers, as is typical of insects surviving the usual spray treatment.

"Red scale were found to live in an oxygen-free atmosphere for as long as 26 hr. Immersed in oil, however, they were found to live as long as 72 hr. A certain percentage of the porgeny of adult scales receiving a sublethal dosage of oil spray die before they are born; some of these are born before they have developed the usual insectan appendages. Because of the absorption of oil by the rough bark, and possibly also because of a lighter deposit of oil caused by the nature of the surface of the bark on the larger branches of citrus trees, it is on these parts of the trees that the greatest difficulty is experienced in the control of scale insects."

Tests of possible substitutes for hydrocyanic acid in fumigation of California red scale, H. L. CUPPLES, H. R. YUST, and J. HILLY (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 611–618*).—The details of toxicity tests on the California red scale with more than 300 chemical compounds are reported.

"Comparatively few of the compounds tested showed a substantial toxic action to the California red scale, and no compound which was not toxic to the scale was found to be markedly effective with hydrocyanic acid. Ethylene oxide is moderately toxic, but concentrations sufficient to kill the scale will injure the foliage. Chloropicrin is toxic to the scale, but also readily

burns the fruit. Practically a complete kill of scale was obtained with hydrogen sulfide at a dosage of 25 percent by volume for 25 min., but, although we have made no tests on foliage with this compound, it is believed that such a dosage would severely injure citrus vegetation. . . .

"We have found that various thiocyanates and isothiocyanates are toxic to the red scale at moderate concentrations, and of these two classes of compounds the former has seemed superior because less injurious to citrus fruit and foliage. Both methyl and ethyl thiocyanates have shown a high toxicity to the scale, with the methyl compound having the advantage of a lower boiling point. Methyl thiocyanate and hydrocyanic acid appear about equally effective in killing the red scale, molecule for molecule, methyl thiocyanate having the superior efficiency in obtaining a complete kill. Because of its lower molecular weight, however, hydrocyanic acid is superior on a weight basis. In some tests on citrus nursery stock, methyl thiocyanate proved inferior to hydrocyanic acid because of greater injury to the foliage.

"In regard to the variation of toxicity with chemical structure, it may be mentioned that in the case of the thiocyanates there was no evidence that the toxicity increased with the molecular weight, or boiling point; in fact, the lower members of the series seemed to be the more effective."

Earth pearls of citrus roots, J. R. WATSON (*Fla. State Hort. Soc. Proc., 47 (1934), pp. 55–57*).—Attention is called to a coccid, provisionally identified as *Margarodes rileyi*, that has been found infesting the roots of unthrifty citrus in groves at Waverly and from Lake Wales to near Fruitland Park, Fla., to a less extent of Bermuda grass, and in small numbers the roots of *Centaurea*. They are found only in sandy soil. Heavily infested trees have a yellow starved appearance and carry dead twigs and branches.

Some further observations on Margarodes in citrus groves, J. R. WATSON (*Fla. State Hort. Soc. Proc., 48 (1935), pp. 90, 91*).—These notes supplement the information (noted above) on this scale, found to infest the roots of citrus trees and a number of other plants, especially grasses.

Some tests of pyrethrum, derris, and nicotine mixtures against cabbage worms, H. C. HUCKETT (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 575–580*).—In work on Long Island, powdered derris root (4.5 percent rotenone, 16 to 18 percent total extractives) at strengths comparable to 4, 3, and 2 lb. of powder per 100 gal. of water gave a higher degree of mortality in the case of the imported cabbageworm than to larvae of the cabbage looper, and further, such mixtures were relatively ineffective to the zebra caterpillar. In the case of the cabbage looper the degree of effectiveness obtained at the highest derris strength was considered scarcely satisfactory.

"In tests with pyrethrum and so-called pyrethrins containing dust mixtures in contact applications for the larvae of the cabbage looper, at strengths of about 0.45, 0.27, and 0.18 percent pyrethrin content for mixtures containing ground pyrethrum flowers and of about 0.2 and 0.1 percent content for mixtures containing an impregnation with extract of pyrethrum flowers, the latter type of dust was the more effective.

"Nicotine sulfate-hydrated lime dusts of 3 and 4 percent nicotine content gave satisfactory results in a heavy contact application for the earlier instars of the zebra caterpillar; in contrast, a lighter application to older larvae of the cabbage looper was ineffective."

Notes and observations on the pistol case-bearer, E. GOULD (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 573–575*).—An outbreak of the pistol casebearer in a large commercial orchard near Ranson, W. Va., in 1927 is said to be the first of importance to be recorded in that State. Since that time there have been

outbreaks in a number of orchards throughout the Shenandoah-Cumberland fruit belt, these being generally distributed throughout the entire region. Thirty-six species of parasites have been reared from this host, 33 from larvae and 3 from the egg. Only 5 of these, namely, *Microbracon pygmaeus* Prov., *Eurydinota lividicorpus* Gir., *Habrocytus* n. sp., *Hemiteles tenellus* Say, and *Meteorus vulgaris* Cress., are normally common enough to be a significant factor in control. The nicotine-oil combination was found to be the most effective larvicide tested for the control of the casebearer. Summer oil used at the rate of 1 gal. per 100, with nicotine sulfate 1:800, is said to be as effective as, and cheaper than, the recommended nicotine-Penetrol combination. Recent work has shown that a 1 percent summer oil applied as an ovicide is very effective in controlling the casebearer. For best results, it is necessary that this spray be applied when the maximum number of eggs are present on the under surface of the leaves.

An experiment for the control of juniper webworm, Dichomeris (Ypsolophus) marginellus Fab., M. G. FARLEMAN (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 493, 494*).—Injury to juniper trees in a nursery, reported in September 1935, was found by the Michigan Experiment Station to be due to larvae of *D. marginellus*. Two plats were sprayed on September 4, (1) with nicotine sulfate (40 percent) 1:400, and (2) with Loro 1:400, both using a sulfated higher alcohol spreader at the rate of 6 oz. in 100 gal. Examination showed that the Loro plat required further treatment. As a safeguard, both plats were sprayed a second time, using nicotine sulfate with the same spreader and at the strength previously employed. In an examination made on September 25, the majority of the twigs, ranging from 3 to 6 linear in., possessed 3 to 8 larvae. Of the 725 larvae found in these samples, 694 had been killed. No spray injury to the juniper foliage was observed.

Further studies of larvicides to control fruit tree leaf roller, with special reference to lead arsenate and supplements, P. J. CHAPMAN and R. W. DEAN (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 561–570, figs. 2*).—The results of further work at the New York State Experiment Station (E. S. R., 73, p. 354) on the control of the fruit tree leaf roller are reported, the details being given at length in tables.

Nearly equal control efficiencies were obtained with a dormant-applied 6 percent oil spray functioning as an ovicide and the better lead arsenate or larvicidal treatments, if the damage attributable to the oil is disregarded. With the same qualifications, maximum efficiencies have been shown to result where both oil and arsenical were used. The dormant sprays applied in these tests caused a reduction in yield as a result of killing or weakening of the buds. This loss was pronounced where the 8 percent oil emulsion was used.

Lead arsenate sprays applied directly after and 7 days after blossoming contributed much more to whatever control was obtained than preblossom sprays in 1935. In one instance the control obtained with the two post-bloom sprays was essentially the same as when a schedule of two pre- and two post bloom sprays was applied. In relation to the development of the insect, these findings suggest that the spray coverage maintained directly after the hatching of the eggs was much more important in protecting the fruit in 1935 than that present immediately before and during hatching.

Lead arsenate used at the rate of 6 lb. per 100 gal. of water gave significantly higher efficiencies than the 3:100 rate in four of five comparisons. Differences in favor of the 6:100 rate ranged from 40.4 percent when combined with fish oil and wettable sulfur to no apparent difference in combination with 0.5 percent mineral oil and wettable sulfur.

Lime-sulfur-lead arsenate combinations were poorer by as much as 15 percent compared with mixtures of wettable sulfur and lead arsenate.

Results obtained with nicotine preparations were not as promising in 1935 as in 1934. Seasonal differences may be the explanation.

In spite of weather conditions which presumably hindered (in 1935) or favored (in 1934) the utilization of lead arsenate for the control of the fruit tree leaf roller, it was possible to obtain essentially the same results both years with comparable mixtures.

Pine-tip moths of southern Ohio, J. B. POLIVKA and J. S. HOUSER (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 494–497*).—In an insect survey of pine plantings made by the Ohio Experiment Station in 1934 and 1935, all species of pine studied, except white pine, either in native stands or in plants, were found infested by one or more of the three species of tip moths that occur in southern Ohio, namely, the Comstock tip moth *Rhyacionia comstockiana* Fern., the Nantucket tip moth *R. frustrana* Comst., and the Zimmerman tip moth *Pinipestis zimmermanni* Grt.

"With the exception of ponderosa pine, those species most seriously infested are those whose native habitat most closely approaches that of the area studied. There is a correlation between abundance of native pine, infestation of native pine, and infestation of plantings of pine species similar in susceptibility to native sorts. In some areas tip moths have caused significant damage both to native stands and to planted areas. The variation in infestation from one year to another by any one species of tip moth may be due to parasitism, but up to now there are no data on this point for southern Ohio."

Variations in codling moth injury in northwestern Arkansas, D. ISELY and H. H. SCHWARDT (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 473–476*).—Records kept by the Arkansas Experiment Station of codling moth injury in the northwestern part of the State from 1918 to 1935, inclusive, and spraying experiments for 11 of the 17 yr. are considered. The severity of infestation is grouped by years as follows:

"Years of very light infestation, when even poorly sprayed orchards were relatively free from worms—1919, 1922, and 1935. Light infestation, when 80 to 90 percent or more of the fruit was free from worms in well-sprayed orchards—1923, 1924, and 1928. Medium infestation, during which severe losses frequently occurred—1926, 1927, 1929, 1930, 1931, and 1934. Possibly 1926 belongs with this last group, and 1930 and 1931 with the following one. Heavy infestation, during which losses in well-cared-for orchards frequently approached 20 to 40 percent—1918, 1920. Most severe injury—1925, 1932, and 1933.

"Among the factors which have been responsible for this variation in abundance of the codling moth, the climatic conditions at the time of flight of moths of the overwintered brood appear to be most important. During the severe years, 1918, 1925, 1932, and 1933, the temperature during May and June was distinctly above normal. During the light years, 1919, 1923, 1924, 1928, and 1935, the temperature during this same period was below the mean. Similarly during years of heavy injury the rainfall was below the mean during the period of flight of moths of the overwintered brood, while during the light years for the same period it was above normal."

It was difficult to find any consistent relationship between the summer weather and codling moth abundance. The temperature hazard to the codling moth in summer seems more likely to be from temperatures that are excessively high rather than from those that are low. Other factors besides acquired resistance and temperature may have brought about a change in the codling moth problem, such as a change since 1918 in a large percentage of the acreage which was

in the moderately susceptible variety Ben Davis and the less susceptible Winesap to the very susceptible varieties Delicious, Stayman, and Golden Delicious.

Codling moth spraying experiments in Pennsylvania in 1935, H. N. WORTHLEY (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 527–532*).—Spraying work conducted by the Pennsylvania Experiment Station in the south-central part of the State, the details of which are given in six tables, indicated that the safest and most effective treatment for codling moth control consists of four first-brood cover sprays of lead arsenate at approximately 10-day intervals from early June to early July, the first two sprays containing fish oil and the last two Black Leaf 155 B or a similar but less injurious formula if one can be developed. For the few orchards where second-brood sprays may be necessary the omission of sulfur after the third week in June is recommended, as summer oil with nicotine sulfate or with Black Leaf 155 A appears to be the only safe and effective substitute for lead arsenate for second-brood codling moth control. Because of the expense of such a schedule, the importance of attempting to secure a high degree of control of the first brood during June is stressed.

Laboratory tests of phenothiazine against codling moth larvae, E. H. SIEGLER, F. MUNGER, and L. E. SMITH (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 532–537*).—In a further study of phenothiazine (E. S. R., 73, p. 808), laboratory work with codling moth larvae has shown that "the initial toxicity of pure phenothiazine is superior to that of lead arsenate. The reduction in the percentage of stings on fruit sprayed with this material is frequently striking. Commercial phenothiazine (55 percent phenothiazine), however, was less effective than lead arsenate, especially when the sprays had been subjected to normal weathering. The physical properties of phenothiazine are in general fairly satisfactory for insecticidal purposes and for an organic compound its cost is relatively low. However, the practicability of using this material as an insecticide for the codling moth can be determined only by adequate experiments under orchard conditions."

Tests of insecticidal efficiency of some contact sprays against codling moth eggs, W. S. HOUGH and R. N. JEFFERSON (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 537–541*).—The details of experiments in which ovicides were used against eggs of the codling moth at Winchester, Va., in 1934 and 1935 and at Blacksburg in 1935 appear in tables.

"Orthol K emulsion at the rate of 2, 3, and 4 qt. per 100 gal. were used alone and in combination with bordeaux mixture, and in each instance ovicidal efficiency was reduced by the bordeaux mixture, but when used at the rate of 4 qt. per 100 gal. the ovicidal efficiency was not reduced to a considerable degree. Oil in combination with bordeaux mixture in the tests of 1935 resulted in a relatively high percentage of control, except in the case of white oil dispersed with pine tar soap to which bordeaux mixture was then added. In this formula the run-off appeared to be excessive. Summer scalecide (a new preparation was used in 1935) failed to give satisfactory control; likewise, paraffin-wax emulsion, except when the undiluted stock emulsion, containing 20 percent wax, was used. A wetting agent (Aresket) at the rate of 0.1 percent by volume caused excessive run-off of all sprays in which it was used. At comparable oil dilutions certain vegetable oils were equal to or slightly more effective than refined petroleum oil as an ovicide in tests on codling moth eggs."

Inheritance of resistance to the hessian fly in the wheat crosses Dawson × Poso and Dawson × Big Club, W. B. CARTWRIGHT and G. A. WIEBE (*Jour. Agr. Res. [U. S.], 52 (1936), No. 9, pp. 691–695, fig. 1*).—Under the conditions of the experiment, conducted at Birds Landing, Calif., the Dawson parent

variety showed 0.4 percent of the plants infested with the hessian fly. For the other parent varieties, Poso and B 8 Club, the percen ages were 96.9 and 98.4, respectively. On the basis of the behavior of F_2 rows, both crosses indicated that inheritance of resistance to the hessian fly is controlled by two genetic factors. It was found that the fly was unable to complete its life cycle on resistant plants. With the knowledge gained, an attempt is being made to breed varieties of wheats for California that will possess resistance to infestation by the hessian fly.

Relative toxicity of some optically active and inactive rotenone derivatives to culicine mosquito larvae, D. E. FINK and H. L. HALLER (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 594–598, fig. 1*).—In the work reported "nearly full-grown culicine mosquito larvae, principally *Culex quinquefasciatus* Say, were used as test insects to compare the toxicity of rotenone, deguelin, optically active and inactive dihydrodeguelin, and optically active and inactive isorotenone, the chemical relationships of which are discussed. Optically active dihydrodeguelin and isorotenone were more toxic than the corresponding optically inactive forms. It is therefore probable that the hitherto unaccountable toxicity of derris extractives can be attributed partly to the optically active deguelin known to be present."

Dosage-mortality curve of pyrethrum sprays on the house fly (Musca domestica L.), D. HOYER, S. Z. VON SCHMIDT, and A. WEFD (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 598–600, fig. 1*).—The effect of pyrethrum sprays on the housefly is shown in table and chart form.

Notes on the apple maggot, P. GARMAN (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 542–544*).—The report of Allen and Fluke (E. S. R., 70, p. 509) showing that the apple maggot can be reared during the winter and the flies utilized for control experiments led to work by the author, who has successfully reared the flies in winter under laboratory conditions at the Connecticut [New Haven] Experiment Station. Lime, talc, and sulfur were found to have considerable repellent action toward oviposition. The adult fly was affected by cryolite almost but not quite as much as by lead arsenate.

A new Ecuadorian fleabeetle injuring crucifers (Coleoptera: Chrysomelidae), H. S. BARBER (*Jour. Wash. Acad. Sci., 26 (1936), No. 4, pp. 181, 182*).—Under the name *Disonycha camposi* n. sp., a description is given of a flea beetle said to damage cruciferous plants at Guayaquil, Ecuador.

Barium carbonate for the bean beetle, L. M. PEARS (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 584, 585*).—Barium carbonate, which has been very extensively marketed under the trade name Baricide as an insecticide for the control of the Mexican bean beetle, was tested during the seasons of 1934 and 1935 in the laboratory and field at Morgantown and at Kearneysville, W. Va.

In laboratory tests it was found to be rather slowly fatal to Mexican bean beetles and their larvae and toxic to blister beetles and to potato beetles, with uncertain results on some flea beetles and nymphs of grasshoppers. Several species of caterpillars ate the poison in laboratory tests without apparent effect; field tests against cabbage butterfly larvae and cabbage loopers likewise showed no protection to the infested plants; fall webworms were resistant, and no other caterpillars tested showed any definite ill effects. It was found that 1 lb. to the gallon gives the best control but that 0.5 lb. or even 0.25 lb. give nearly as good control commercially.

It appears that Baricide does not equal the best of the standard materials such as magnesium arsenate and some of the fluosilicates, although satisfactory control in moderate infestations at least may be secured from its use. Further, Baricide may be recommended only where cost of material and amount

of labor required are not important factors and where poisonous residues are particularly objectionable. Since such conditions obtain with a great number of growers of beans, it appears that there may be a definite place for this material, with all its limitations, as an insecticide for bean beetle control.

Effects of some inorganic salts on development and reproduction of the bean weevil (Acanthoscelides obtectus), R. J. BUSHNELL (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 509–514*).—Following a brief reference to the literature, experiments which have shown an inhibiting influence by potassium chloride and sodium sulfate on the oviposition of the bean weevil when the ovipositing females have been reared in normal beans are reported. Other salts that were used appeared to have slight or no influence on oviposition. Ferric sulfate in sufficient amounts increased the duration of the larval stage of the bean weevil. Sodium chloride, sodium nitrate, and potassium chloride in the larger quantities affects the development of the bean weevil by increasing the duration of the larval, prepupal, and pupal stages. This effect is apparent whether the beetles are reared at 25° or 30° C., but the differences in developmental rates are greater at the lower temperature. The effect of the sodium salts on the weights of bean weevils appears to depend upon whether they contain monovalent or bivalent anions. It was shown that those salts which cause a decrease in weights of the young adult bean weevils also cause a decrease in the number of offspring obtained.

Dust treatments for protecting beans from the bean weevil, H. O. DEAY and J. M. AMOS (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 498–501*).—The results of experiments set up in 1933 are reported in detail in a table.

"Untreated navy beans were 54 percent infested by bean weevils when exposed to their attack for 6 mo. Anderson clay, Dawson clay, Dutox, and dusting talc at all dilutions used gave perfect or nearly perfect protection to navy beans from infestation by the bean weevil. Hydrated lime was a little less efficient than the foregoing materials but still very effective at all dilutions used. Coal ashes prevented infestation at dilutions of 1:2 and 1:4 and allowed less than 0.5 percent infestation at dilutions of 1:10 and 1:25. Wood ashes gave perfect protection at dilutions of 1:2 but allowed an infestation of 1 percent or more at greater dilutions. Flour was ineffective at dilutions of greater than 1:2. It gave perfect protection at dilution of 1:1 in preliminary tests. The protection afforded by the nonpoisonous dusts, especially at high dilutions, is definitely correlated with the adhesivity of the material. None of the materials used affected the cooking quality or taste of the beans, but materials that adhered well and wrinkled the seed coat were much harder to remove by washing. None of the materials used affected germination of the beans."

Partial second brood of plum curculio in Virginia, W. J. SCHOENE (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 571–573*).—It is concluded from a study at the Virginia Experiment Station of the life history of the plum curculio and other data that Virginia is on the border line between the one-brooded and the two-brooded areas, and that in seasons that are favorable to the curculio a partial second brood occurs.

The apple flea weevil, J. S. HOUSER and R. B. NEISWANDER (*Ohio State Hort. Soc. Proc., 69 (1936), pp. 10–15*).—This contribution from the Ohio Experiment Station reports upon the present status of the apple flea weevil, a bulletin on which, by the author, has been noted (E. S. R., 51, p. 257). The pest has been found to be attacked by 22 species of parasites and a fungus disease, which occasionally become so abundant that an infestation may be nearly eliminated.

Control work with insecticides in 1934 and 1935 has shown fluorine to be peculiarly and particularly toxic to insects of the apple flea weevil group. The application (1) of Dutox, a patented barium fluosilicate product, or (2) of Kalo Spray, a specially prepared natural cryolite, at the rate of 5 lb., with flotation sulfur 8 lb., Goulac 3 oz., and water 100 gal. during the pink and prepink periods is recommended.

The use of flotation sulfur in the preblossom spray, fluorine being incompatible with lime-sulfur, prevented scab damage as effectively as lime-sulfur used at the conventional strength.

The apple flea weevil, J. S. HOUSER and R. B. NEISWANDER (*Midwest Fruitman, 9 (1936), No. 10–11, pp. 5, 9, 10*).—A practical account based on the above.

A new and effective control for apple flea weevil, J. S. HOUSER and R. B. NEISWANDER (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 481, 482*).—In this further contribution the efficiency of fluorine in combating the pest is emphasized.

"A comprehensive series of spray plats was executed in 1934 at Medina, Ohio, and repeated with slight modifications in 1935 at Medina and at Jackson, Ohio. In all three series, fluorine was outstandingly successful to the extent that in plats so treated flea weevil damage was reduced to a point considerably below that of significant injury. The formula used was Dutox or Kalo spray 5 lb., flotation sulfur 8 lb., Goulac 3 oz., [and] water 100 gal. One application was made during the pre-pink period and another when the apple buds were in the full-pink stage. In each instance the under side as well as the upper side of the foliage was covered, with particular attention given to the inner portions of the tree. Plats sprayed with Kalo spray were slightly less damaged by flea weevil than were the Dutox plats."

Quantitative demonstration of the presence of spores of Bacillus larvae in honey contaminated by contact with American foulbrood, A. P. STURTEVANT (*Jour. Agr. Res. [U. S.], 52 (1936), No. 9, pp. 697–704*).—In continuation of earlier work (E. S. R., 68, p. 360), in which it was found to be possible to demonstrate the presence of spores of *B. larvae*, the cause of American foulbrood, in samples of commercial honey that had had contact with American foulbrood in the course of their production or preparation for the market, the author has developed a quantitative method for determining the approximate number of spores per cubic centimeter in such honey. The method, which is similar to that employed by Breed and Brew at the New York State Experiment Station (E. S. R., 35, p. 70) for counting bacteria in stained smears of milk, is described, and formulas are given for calculating the number of spores per cubic centimeter in honey. Data obtained, using samples of honey of known spore contents, are given with the formula for calculating the mean spore count per field that theoretically should be recovered from such samples, as derived from actual spore counts per field of stained sediments from honey. A statistical analysis of the data indicates that the method used is sufficiently accurate for determining the spore content of unknown honeys. The formulas for calculating the data, with permissible limits of error, are also given.

Distribution of the Argentine ant in the United States and suggestions for its control or eradication, M. R. SMITH (*U. S. Dept. Agr. Circ. 387 (1936), pp. 40, figs. 24*).—This contribution deals with the distribution and abundance of the Argentine ant, control and eradication work in Mississippi, and the method recommended for its control or eradication.

The pest has been found in all types of soil and at elevations ranging from approximately sea level to nearly 4,000 ft. "They seem to be affected by strong winds and by moisture conditions in the soil. Although tropical insects, they can withstand more cold than most of our native ants. It is estimated that

the Argentine ant occurs over an area of at least 4,000 sq. miles in the United States. California and Louisiana are the most heavily infested States, and infestations also occur in Mississippi, Alabama, Georgia, Texas, South Carolina, Arkansas, North Carolina, Florida, Maryland, Tennessee, Arizona, Missouri, and Illinois (States listed in order of decreasing size of infested area). The size of the infestations varies from a single colony to areas containing several hundred square miles. Although as yet the ants are sporadically distributed over the States mentioned, except in Missouri, Maryland, and Illinois, where the infestations are of the indoor type, there is nothing to prevent them from occupying the entire area within their present boundaries and also from spreading to additional territory.

"Efforts to control and eradicate the Argentine ant in Mississippi by poisoning campaigns have resulted in freeing 39 out of 245 infested localities and reducing the infestations in nearly all the others. The method used in Mississippi is therefore described in some detail. . . . The ants can be controlled by one thorough campaign, and by repeating the campaign each fall it is possible to eradicate them in from 2 to 5 yr. The method consists, in brief, in making careful surveys of infested areas and then placing cups of sirup containing sodium arsenite at proper intervals throughout these areas. Where eradication is attempted, supplementary measures, such as burning and oiling colonies, expedite the work, although these should not be resorted to until the numbers have been greatly reduced. The cost of eradicating ants should not be more than 3 ct. per cup of poison or $3 to $6 per block."

A list is given of 18 references to the literature.

The female sex of the genus Photomorphus (Mutillidae), C. E. MICKEL (*Ann. Ent. Soc. Amer., 27 (1934), No. 4, pp. 610–613; abs. in Minnesota Sta. Rpt. 1935, p. 32*).—A description is given of the male mutillid wasp, of which the female was described by Cockerell in 1895 as *Sphaerophthalma myrmicoides*. The species is assigned to the genus *Photomorphus*.

Problem of European red mite on prunes in western New York, T. W. REED (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 546–550, figs. 4*).—In control work at the New York State Experiment Station with the European red mite, probably the most serious pest attacking prunes in western New York, the dormant oil treatment was found helpful in checking the pest, although in a hot, dry season it may increase to serious numbers. Lime-sulfur is effective in killing the mites, but the burning effect on the foliage is often too severe and may reduce the yield. The summer oils applied either at the shuck-fall spray or later in the summer killed not only the mites but prevented the eggs from hatching. However, when applied in July or August the summer oils, although not actually injuring the fruit, do produce spotting, and this detracts from its appearance at picking time. When summer oil was applied with bordeaux at the shuck-fall stage, no spotting was noticeable and the mites did not become numerous. They had increased in numbers by September, but since the fruit is usually picked before September 15 and since the foliage at this season is tough and rather dry, the mites produced no noticeable injury. It was observed in various plantings that the mites were less numerous on those trees on which no sulfur had been used than on those which had been treated with sulfur sprays or dusts.

The data suggest that the more vigorous a planting the less is the harmful effect of mite population or lime-sulfur. In fact it seems logical to assume that proper fertilization and care of the planting are the first and most important steps in a European red mite control program.

Derris insecticides.—VI, Summer control of European red mite on apple with derris and neutral wetting agents, R. E. HEAL (*Jour. Econ. Ent., 29*

(*1936*), *No. 3, pp. 550–556*).—In continuation of this study at the New Jersey Experiment Stations (E. S. R., 73, p. 647), field tests were carried out on the summer control of the European red mite on apple trees the foliage of which retained sulfur and arsenical residues. "Sprays containing derris in various proportions in combination with different wetting agents were used. Derris was supplied in three forms, a dust of 1 percent rotenone content, a dust of 0.75 percent rotenone content, and a finely ground root of 4 percent rotenone content. Aresket, Areskap, and Aresklene, skim milk, and soap were used as wetting agents. The combination which was shown to be most satisfactory consisted of 1.25 to 2 lb. of derris root (4 percent rotenone) and 10 oz. of Aresket or Areskap to 100 gal. of spray. The outstanding feature of this spray, beyond its toxicity to the pest, was its compatibility with sulfur and lead arsenate deposits on the foliage, the presence of the former precluding the use of any oil spray, and the presence of the latter estopping the use of any spray containing soap. Two applications spaced at a period of from 1 to 2 weeks apart were necessary to effect control. The length of period between applications was dependent on the rate of development of the immature stages of the mite. Thorough application was found to be essential for the effective use of this spray.

"Derris dust of 1 percent rotenone content was of no value in the control of this pest when applied as a dust."

ANIMAL PRODUCTION

[**Investigations with livestock in Florida**] (*Florida Sta. Rpt. 1935, pp. 51, 52, 53, 54, 56–58, 72, 129, 134–136, 137, 138, 149–152*).—The results obtained in tests with beef cattle are reported on grading up native cattle by the use of purebred bulls, by A. L. Shealy; the efficiency of the trench silo for preservation of forage crops as measured by chemical means and by the utilization of the nutrients of the silage by cattle, by Shealy, W. M. Neal, and R. B. Becker; at the Everglades Substation mineral supplements for young calves and cut sugarcane for range cattle, both by R. W. Kidder; at the North Florida Substation the feeding value of sorghum silage, peanut hay, and cottonseed hulls as roughages in fattening steers, by L. O. Gratz and R. M. Crown; and at the West Central Florida Substation the milk production of Red Polled cows, birth weight of purebred and grade Red Polled calves, comparison of digester tankage and cottonseed meal for wintering mature cows and yearling heifers, and the mineral intake of dual-purpose and native cattle.

Swine studies yielded results on a comparison of corn, sweetpotatoes, and Spanish peanuts with dry lot feeding for pork production, and fattening fall pigs for spring market on runner peanuts and sweetpotatoes, both by W. W. Henley; and at the North Florida Substation a comparison of gains made by swine on corn, corn and tankage, corn and cowpeas, corn and peanuts, and Spanish peanuts, by Gratz and Crown.

Studies on the adaptability of Columbia sheep to Florida conditions are reported from the North Florida Substation, by Gratz and Crown.

In tests with poultry, information was obtained on the effect of feeding crotalaria seed to chickens and other birds, by M. W. Emmel; a comparative study of corn and liquid milk v. a grain and mash ration in feeding for egg production, a comparative study of the value of meat scrap, fish meal, and milk solids as sources of protein for egg production, and lights v. no lights for egg production, all by N. R. Mehrhof and E. F. Stanton; the physical properties of eggs from hens on experimental diets; the storage of eggs; and at the West Central Florida Substation on confinement v. range rearing of chicks, the

importance of range rotation in poultry production, egg production and mortality from pullets reared under confinement v. range conditions, the comparative value of milk solids, ground peanut kernels, meat meal, and fish meal in fattening broilers and fryers, and all-night lights v. no lights on Single Comb White Leghorn hens, all by Mehrhof, Emmel, and W. F. Ward.

[Investigations with livestock in Idaho], H. P. MAGNUSON, C. W. HICKMAN, C. E. LAMPMAN, J. TORVS, and R. F. JOHNSON (*Idaho Sta. Bul. 220 (1936), pp. 7, 8, 20–22, 43–45, 50, 51, 53–56*).—Results obtained in experiments with cattle are reported on phosphorus deficiencies in cattle in various parts of the State, the carotene content of pasture grasses, the negative effect of phosphorus supplements in steer fattening rations, and at the Caldwell Substation a comparison of light and heavy silage feeding for fattening steers, feeding steers with and without minerals, feeding yearling steers on pasture, and the carrying capacity of different pasture grasses.

Studies with swine produced data on bone inequalities in the foot development of swine, and the inheritance of inverted nipples.

In tests with sheep information was reported on the negative effects of phosphorus in lamb fattening rations at the Caldwell and Aberdeen Substations, and a comparison of light and heavy silage feeding for fattening lambs at the Caldwell Substation.

Poultry tests led to information on the high vitamin A requirements of laying hens, the need of animal protein supplements in rations containing peas, and confined v. range rearing of birds.

[Investigations with livestock in Michigan], G. A. BROWN, H. R. HUNT, and C. G. CARD (*Michigan Sta. Rpt. 1935, pp. 159–161, 230, 231, 238, 239*).—Studies with livestock yielded results on limited v. liberal rations for the development of draft colts, finishing steer and heifer calves, and silage v. shocked corn for beef cattle.

In swine tests information was obtained on the allowance of skim milk for growing and fattening pigs, alfalfa meal as a protein supplement for brood sows, and corn and barley for pigs on pasture.

Sheep studies produced results on winter rations for breeding ewes, methods of self-feeding and amounts of roughage desirable for fattening lambs, and cross-breeding and selection for the improvement of wool and other characters.

In poultry work progress was made in a comparison of different pasture crops for growing poultry, the effect of artificial heat on egg production of pullets during the winter months, and a comparison of electric and coal brooders in the production of winter broilers.

[Investigations with livestock in Montana] (*Montana Sta. Rpt. 1934, pp. 49, 50–52, 66–68, 72–77*).—Results obtained in tests with beef cattle are reported on the value of adding cottonseed cake to a barley and alfalfa ration, and of substituting dried beet pulp for part of the barley in rations for fattening calves; at the Northern Montana Substation on the use of locally grown feeds for winter maintenance of mature cows, the disadvantage of feeding breeding cows for heavy gains during the winter, feeding wheat and barley to finishing yearling steers, full v. light winter rations in developing heifers, and effect of type of sire on birth and mature weight of heifers. At the U. S. Range Livestock Experiment Station progress was made in the development of economical rations for wintering cattle on the range and in the feed lot.

In sheep studies, information was obtained on summering ewes and lambs on the forest, dried beet pulp and alfalfa for wintering breeding ewes, a limited roughage ration for breeding ewes, and limited and full feeding of ewe lambs. At the U. S. Range Livestock Experiment Station a comparison was made of cot-

tonseed cake and corn as supplements for wintering ewes on the range, and data obtained on methods of wintering ewe lambs.

Swine tests at the U. S. Range Livestock Experiment Station were concerned with the production of quality bacon from hogs raised on irrigated alfalfa pasture and cereal grains.

Turkey studies at the U. S. Range Livestock Experiment Station produced results on the protein, mineral, and vitamin requirements of turkeys, growing and fattening turkeys, and the feed requirements of breeding turkeys.

[Experiments with livestock in South Dakota], J. W. WILSON, K. W. FRANKE, and W. E. POLEY (*South Dakota Sta. Rpt. 1935, pp. 14, 15, 17, 18, 19, 45, 46*).—Information obtained in tests with beef cattle are reported on the substitution of tankage for linseed oil meal in rations for calves, the value of Russian-thistles and Sudan grass as roughages, and the value of tankage as a supplement to corn and alfalfa hay for baby beef production.

In the swine tests results were obtained in fattening summer pigs on South Dakota grains, Russian-thistle and pigweed as pastures for pigs, and attempts to feed soybeans with corn to avoid soft pork.

Poultry studies yielded evidence on the values of white corn and milk in growing turkeys, turkey egg hatchability, and the value of oats and millet in growing and laying rations for pullets.

The effect of retarded growth upon the sexual development of rats, S. A. ASDELL and M. F. CROWELL (*Jour. Nutr., 10 (1935), No. 1, pp. 13–24*).—This study involved the use of three groups of rats on different planes of nutrition, one group receiving an optimum ration, the second group kept at an average weight of 40 g, and the third group at 80 g. When signs of failure were observed both restricted groups were allowed to gain 10 g in weight. Throughout the trial energy intake was the only limiting factor in the diet.

It was observed that the age at opening of the vagina increased while weight at opening decreased with severity of diet restriction. Evidently age is a more important consideration than weight in this respect. The increased severity of treatment increased the age and weight interval between the vaginal opening and the occurrence of first oestrum, these two events becoming entirely dissociated with severe restriction. Cornified vaginal smears were common in the normal rats but never observed in the restricted groups. The cornified rats weighed less than those with regular cycles, and the latter in turn weighed less than anoestrous rats. When energy above maintenance was supplied, both growth and sexual activity occurred until increased growth increased maintenance to the level of energy intake, then both growth and sexual activity ceased. Occurrence of an oestrous smear is considered a delicate indication of increased energy supply. A sex deformity observed in deprived males and the mode of action of the anterior hypophysis are each discussed briefly.

The role of calcium and phosphorus in determining reproductive success, W. M. COX, JR., and M. IMBODEN (*Jour. Nutr., 11 (1936), No. 2, pp. 147–176, figs. 8*).—This extensive investigation involved the use of 145 female rats, in 20 groups of 5 each, which had been studied for 10 consecutive reproductive cycles while receiving diets of purified foodstuffs containing varying levels and ratios of calcium and phosphorus.

The results are evaluated on the basis of the average weight of the young at 21 days, the percentage of ash in the young, and the change in weight of the mother throughout the cycle. A calcium-phosphorus ratio of 1 at a calcium level of 0.49 percent was adjudged the ideal level and ratio for successful gestation and lactation. Excessive mineral intake produced poor results regardless of ratio, while phosphorus in excess was better tolerated than excess calcium.

Factors affecting the carotene content of alfalfa hay and meal, H. R. GUILBERT (*Jour. Nutr., 10 (1935), No. 1, pp. 45–62, fig. 1*).—In this study at the California Experiment Station in cooperation with the U. S. Department of Agriculture, extensive tests were conducted to measure the degree of carotene destruction in alfalfa under various methods of handling.

Little or no loss occurred in vacuum drying. Very rapid losses occurred when fresh alfalfa was sun-dried or when dried alfalfa was exposed to either direct sunlight or sunlight filtered through ordinary glass. Autoclaving resulted in significant losses, and the destruction of enzymes by this process reduced but did not eliminate further loss when the hay was subsequently sun-dried. Enzyme action was found to be an important factor in carotene losses and under unfavorable drying conditions may cause extensive destruction. Temperature proved a major factor in determining the amount of carotene loss during storage. During 8 weeks' storage at −5° to 5° C. no loss was observed, while at 20° to 30° 30 percent losses occurred, and 9 days' storage at 60° and 80° gave 62 and 87 percent losses, respectively. Large losses were also noted in both dehydrated and sun-cured meal in a warehouse during hot weather.

It is pointed out that no broad generalities regarding the relative values, based on curing methods, should be made without consideration of the carotene content of the original hay and unless effective means are employed to prevent deterioration in storage.

The comparative digestibility of artificially dried pasture herbage by sheep and rabbits, C. J. WATSON and W. GODDEN (*Empire Jour. Expt. Agr., 3 (1935), No. 12, pp. 346–350*).—The digestibility of 5-week-old artificially dried herbage, consisting of mixed grasses and clover, was determined by digestion trials with four male rabbits and two wether sheep. The coefficients of digestibility for nitrogen, ether extract, crude fiber, and nitrogen-free extract were 61.5, 25.8, 26, and 55.9, respectively, for the rabbits, and 76.7, 51.8, 74.5, and 81.4, respectively, for the sheep.

Lake vegetation as a possible source of forage, R. A. GORTNER (*Science, 80 (1934), No. 2084, pp. 531–533; abs. in Minnesota Sta. Rpt. 1935, p. 34*).—In this article from the Minnesota Experiment Station the author shows the dry matter, ash, crude protein, and crude fiber content and indicates the feeding value of 16 different kinds of lake water vegetation from representative Minnesota lakes. These forages were generally characterized by a high protein, high lime, and low fiber content.

Commercial feeding stuffs, L. S. WALKER and E. F. BOYCE (*Vermont Sta. Bul. 404 (1936), pp. 46*).—This is the usual report of the analyses for protein, fat, and fiber of 2,343 samples of feeding stuffs collected for official inspection during December 1935 (E. S. R., 74, p. 678).

Judging the age of sheep by their teeth (*Montana Sta. Circ. 149 (1936), pp. 4, figs. 6*).—This study covers the examination of the teeth of 2,300 Rambouillet sheep of known age, all of good quality, but not especially fed or cared for. Diagrams are presented showing the variations in stage of development of teeth at different ages with the percentage of each age group falling in the various classes.

It is evident that there is considerable overlapping of the stage of teeth development from one age group to the next, so that in a rather large percentage of cases it is impossible to determine the correct age. This is illustrated by the fact that the teeth of 57 percent of the 2-year-olds and 28 percent of the 3-year-olds appeared alike.

The effect of the plane of nutrition of ewes upon their wool, lamb, and milk production, M. G. SNELL (*Louisiana Sta. Bul. 269 (1936), pp. 23, figs. 9*).—

In an attempt to determine the cause of excessive shedding of wool by sheep on cut-over range areas in Louisiana, demonstratively not due to scab, a 3-yr. experiment was conducted with four lots of 10 ewes each, fed in dry lot. Lot 1 ewes received a full feed (60 parts hay, 40 parts grain) continuously; lot 2 ewes were fed the same as lot 1 ewes for 8 mo. but for 4 mo. (representing the winter range condition) they were fed only one-third as much as those in lot 1; lot 3 ewes received two-thirds as much; and lot 4 ewes one-third as much as did the lot 1 group.

Lot 1 ewes showed greater gains in weight, produced more wool with fiber of greater length and diameter and less crimp, gave birth to more lambs, and produced more milk daily than any of the other lots. No shedding of wool occurred in this group.

Lots 2, 3, and 4 gave successively poorer results in each of these respects, with each group showing a tendency to shed. All of the original ewes in group 4 died before the end of the 3-yr. period.

There was little difference in birth weight or weight at 120 days of lambs from groups 1, 2, and 3, while lambs from group 4 were significantly smaller at birth and at 120 days. The low plane of nutrition in the experiment did not increase the ability of the ewes to digest feed.

Dry beet pulp, wet pulp, and dried molasses pulp, for fattening lambs, W. F. DICKSON and D. HANSEN (*Natl. Wool Grower, 26 (1936), No. 1, pp. 27, 28*).—The results from trials with 10 lots of 30 lambs each, fed over a 71-day fattening period, are reported by the Montana Experiment Station.

The addition of either wet or dried beet pulp to rations of oats and alfalfa or barley and alfalfa increased the rate and decreased the cost of gains. The dried pulp produced faster and cheaper gains than wet pulp in the oat-alfalfa ration, while in the barley-alfalfa ration dried pulp produced faster gains but at a slightly higher cost than wet pulp. A ration of barley, cottonseed cake, wet beet pulp, and oat straw produced both faster and cheaper gains than when dried pulp replaced the oat straw, the former giving the most economical gains of any ration tested. It is also noted that monocalcium phosphate failed to equal cottonseed meal as a supplement to a barley, alfalfa, and wet pulp ration. There was an average death loss of 5 percent with losses occurring in 8 of the 10 lots. This is higher than had been experienced during the last few years.

Self or hand-feeding for fattening lambs, F. BARNUM and W. F. DICKSON (*Natl. Wool Grower, 26 (1936), No. 4, p. 26*).—In this single trial at the Montana Experiment Station the data indicate that the group of self-fed lambs ate more feed per day, made more rapid and economical gains, were better finished, and dressed heavier than hand-fed lambs. While the heavier lambs in both groups gained faster than the lighter lambs, self-feeding favored the light lambs more than the heavy lambs.

The effect of age upon the weaning weight of range lambs, W. F. DICKSON and F. BARNUM (*Natl. Wool Grower, 26 (1936), No. 3, pp. 22, 23*).—The Montana Experiment Station has made a study of the weights of 2,130 Rambouillet lambs at weaning time covering a 3-yr. period.

It is noted that (1) single lambs weighed about 10 lb. heavier than twin lambs of the same age, (2) the oldest single lambs (from 160 to 169 days) averaged 17.5 lb. heavier and the oldest twin lambs 18.8 lb. heavier than the youngest (from 100 to 109 days) respective groups, and (3) the weight trends of the different age groups indicate that twin lambs were gaining faster than single lambs of the same age at weaning time. The management of flock at breeding time in order to obtain most favorable lambing is briefly discussed.

[Investigations with poultry in New Jersey] (*New Jersey Stas. Rpt. 1935, pp. 4, 5, 7, 78–81*).—Data obtained in experiments with poultry are reported on the vitamin A requirements of the chicken, the role of tryptophane in the nutrition of the chicken, methods of measuring egg size to serve as a basis for the selection of future breeding stock, the size of eggs produced during the hatching season, mortality rates in egg-laying contests between 1916 and 1933, and production records of birds in individual cages.

A note on the structure of egg white, P. J. SCHAIBLE, J. M. MOORE, and J. A. DAVIDSON (*U. S. Egg and Poultry Mag., 41 (1935), No. 12, pp. 38, 39, figs. 2*).—This brief report from the Michigan Experiment Station describes a simple method for observing the structure of egg white. The authors conclude "it is evident that the firm white is of laminated structure, composed of concentric layers containing mucin fibers."

A method of measuring the strength of the yolk membrane, S. S. MUNRO and G. ROBERTSON (*U. S. Egg and Poultry Mag., 41 (1935), No. 12, pp. 48, 50, fig. 1*).—A technic is described for measuring the breaking strength of the vitelline membranes in terms of millimeters of mercury in a vertical column. The average breaking strength of the membranes of 557 fresh eggs was 27.05 mm of mercury.

Factors modifying egg production with special reference to seasonal changes, E. O. WHETHAM (*Jour. Agr. Sci. [England], 23 (1933), No. 3, pp. 383–418, figs. 8*).—Data on seasonal variations in egg production are presented for different latitudes and correlated with different amounts and quality of light. It is considered that the influence of light is due to its action on the anterior lobe of the hypophysis, stimulating the production of the hormone. Hens with low levels of production were most affected by variations in the light.

The effect of variation in the calcium-to-phosphorus ratio on the utilization of nitrogen, calcium, and phosphorus by the growing chick, C. W. ACKERSON, M. J. BLISH, and F. E. MUSSEHL (*Nebraska Sta. Res. Bul. 83 (1936), pp. 11*).—In this study three groups, totaling 123 chicks, were fed accurately known amounts of rations (hand-fed as pellets) containing varying percentages of calcium, with liberal provision of the antirachitic factor so that conditions for assimilation and deposition were favorable. The percentage retention of nitrogen, calcium, and phosphorus was determined by comparative slaughter tests, comparison being made between newly hatched chicks and chicks which had been fed for several weeks.

About 37 percent of the ingested nitrogen and 28 percent of the phosphorus was retained in each of the three lots, while the percentage of calcium retention amounted to 35, 24, and 13 on the 0.9, 1.5, and 2.3 percent calcium rations, respectively. No significant change in the percentage composition of the chicks or the gains made by them was noted.

The amino acid content of eggs and chicks: Relation to diet and to incidence of chondrodystrophy, A. R. PATTON and L. S. PALMER (*Jour. Nutr., 11 (1936), No. 2, pp. 129–134*).—This investigation from the Minnesota Experiment Station reports significant differences in the glycine content of normal and chondrodystrophic chick embryos. Only slight variations occurred in the content of the other amino acids determined.

Eggs from hens fed an optimum ration and glycine-deficient rations showed no significant differences in the amino acid content of the egg proteins. Feeding glycine to hens in moderate amounts did not affect the glycine content of the eggs, while larger doses proved toxic. It is noted that incubated eggs contained more glycine than fresh eggs, indicating its synthesis during embryonic development.

The vitamin A reserve of embryo and baby chicks, A. D. HOLMES, F. TRIPP, and P. A. CAMPBELL (*Jour. Nutr., 11 (1936), No. 2, pp. 119–128, figs. 2*).—Data are presented on the vitamin A reserve of embryo and baby chicks determined by assaying the livers by the antimony trichloride colorimetric method. The unabsorbed egg yolk was also assayed.

For groups of eighteenth-day embryos, 6-hour old chicks, and 24-hour-old chicks the livers weighed 0.51, 0.89, and 1.1 g and contained 7, 12, and 19 blue units of vitamin A, respectively, while the vitamin A content of the unabsorbed yolk of these groups was 80, 58, and 44 blue units, respectively. The large store of vitamin A in the yolk undoubtedly influenced the rapid increase in the vitamin A content of the livers of chicks during the first few days after hatching.

Growth promoting effect of flavine on the chick, S. LEPKOVSKY and T. H. JUKES (*Science, 82 (1935), No. 2127, p. 326*).—A brief report is made confirming the conclusions of Elvehjem and Koehn (E. S. R., 73, p. 277) that flavine is powerless to prevent a pellagra-like syndrome in chicks caused by feeding a heated basal diet. The syndrome was prevented by the filtrate from liver extract after the flavines were removed.

When an unheated diet of the same composition was fed, slow growth occurred and growth was markedly accelerated by the addition to the diet of the fuller's earth adsorbate containing the flavine. It is concluded that liver extract contained two water-soluble factors which promote growth in chicks and that both factors are distinct from vitamin B (B_1).

The effect of feeding deaminized versus untreated cod liver oils on growth, egg production, and mortality of poultry, H. S. GUTTERIDGE (*Canada Dept. Agr. Pub. 475 (1935), pp. 29, fig. 1*).—The six samples of cod-liver oil and one sample of pilchard oil analyzed contained measurable quantities of nitrogenous material, ranging from 0.0003 percent in purified medicinal cod-liver oil to 0.031 percent in sun-rendered cod-liver oil, with an observed tendency for the oils high in nitrogenous material to also be high in free fatty acids. The removal of these nitrogenous fractions by chemical processes resulted in greater growth of young chicks, particularly cockerels, and also in more efficient use of the feed for egg production and maintenance and gain in body weight during the first laying year. It is concluded that oils produced under such conditions as to contain relatively high amounts of these nitrogenous fractions should not be used for poultry feeding purposes.

The effects of varying amounts of animal protein fed to White Leghorn pullets.—II, Factors correlated with egg-size and number of eggs, C. C. RHODES, L. H. BARTEL, and P. E. F. JOOSTE (*Empire Jour. Expt. Agr., 3 (1935), No. 12, pp. 313–319*).—By further summary of the data presented in part 1 of this study (E. S. R., 74, p. 834), the existing correlation between various characteristics of a pullet and the eggs she lays has been determined.

Egg weight was significantly correlated with average monthly body weight for all groups, with maximum body weight in the medium and high protein groups and with average body weight only in the medium protein group.

Annual egg production was highly correlated with winter (4 mo.) production and was negatively correlated with days out of production.

Oats for chickens, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bimo. Bul. 181 (1936), pp. 95–98*).—Continuing these studies (E. S. R., 63, p. 862), it was found that oats rations regardless of the form of oats fed or the method of feeding were decidedly superior to yellow corn rations without oats for egg production. Germinated oats gave good hatchability of eggs. Hulled oats were slightly better than other forms of oats from the standpoint of egg production and feed consumption. There was no evidence to support the conten-

tion that corn was superior to oats for the maintenance of body weight of layers. As much as 40 percent of oats could be fed without ill effects on the birds.

Since employing the free-choice system of feeding whole oats, troubles with feather picking, cannibalism, and pick-outs have largely disappeared, even where chicks or laying pullets were subjected to very severe conditions of confinement.

The oats could be fed in a variety of ways, but the inclusion of a large amount in a yellow corn ration led to a deficiency of vitamin A. This deficiency could be corrected by providing other sources of this vitamin, such as cod-liver oil or succulent green feed.

The management of laying hens in cages, W. C. THOMPSON (*U. S. Egg and Poultry Mag., 42 (1936), No. 1, pp. 24–27, fig. 1*).—In a preliminary study at the New Jersey Experiment Stations, 108 White Leghorn pullets were placed in individual wire cages on November 1 and kept on trial under close confinement for 1 yr. The pullets averaged 147.76 eggs per bird and returned a profit over feed cost of $2.77 each. No unusual conditions were encountered which could be attributed to the cage management. The greatest disadvantage was the increased initial cost for cage installation, but this was partially offset by the larger number of birds housed per unit of floor space and the saving in cost of labor and litter.

Wheat gray shorts for the prevention of slipped tendons in battery brooder chicks, R. M. SHERWOOD and J. R. COUCH (*Texas Sta. Bul. 525 (1936), pp. 25*).—A series of four studies is reported in which White Leghorn chicks were fed in battery brooders on various experimental rations. Data are presented on the frequency of slipped tendon, the rate of gain in live weight, and the feed requirement per unit of gain for each group.

The substitution of 20 percent of wheat gray shorts for a like amount of ground corn or ground kafir produced more rapid gains and fewer slipped tendons and required less fed to produce a unit of gain than did rations not containing the shorts. Rations containing 30 percent produced more rapid gains but required more feed per unit of gain than the rations containing 20 percent shorts. Rations containing wheat gray shorts milled from hard wheat produced fewer slipped tendons and more rapid gain, but required more feed per unit of gain than a ration containing soft wheat shorts. In three rations with different calcium-phosphorus levels with and without shorts, the presence of shorts had a greater effect on gain in weight, prevention of slipped tendons, and feed required per unit of gain than did the various calcium-phosphorus levels.

The effect of cooling eggs on the size of the air cell, E. M. FUNK (*U. S. Egg and Poultry Mag., 42 (1936), No. 1, p. 30, fig. 1*).—In this brief note from the Missouri Experiment Station, data are presented to show that cooling eggs to low temperatures produces an air cell of considerable size. It is suggested that in grading eggs some tolerance should be allowed for the effect of cooling on the size of the air cell.

Results of cooling eggs by different methods on farms, E. M. FUNK (*U. S. Egg and Poultry Mag., 41 (1935), No. 5, pp. 14–18, 62–64, figs. 7*).—In this contribution from the Missouri Experiment Station, it is noted that the time required to cool eggs from high temperature (from 92° to 102° F.) to below 68° in a 50° room was 1, 3, 5, 10, and 16 hr. for a single egg, eggs on a wire tray, in a wire basket, in a galvanized pail, and in a case, respectively. Circulation of air in the cooler greatly hastened the rate of cooling, especially when the eggs were held in wire trays or baskets.

Assuming a cooling efficiency of 100 percent for a single egg held in the cooler without forced air circulation, the cooling efficiency of the eggs held in various containers was for a wire tray 37 percent, a wire basket 27 percent, a wire basket with air circulation 120 percent, a galvanized pail 16 percent, and in a case 8 percent. Chilling and lining or wrapping the case retarded the rate of rise in temperature when the eggs were removed from the cooling room.

Freezer burn on refrigerated poultry, D. K. TRESSLER (*U. S. Egg and Poultry Mag., 41 (1935), Nos. 9, pp. 33–46, figs. 2; 10, pp. 38–41*).—This article from the New York State Experiment Station presents a critical review of the literature dealing with freezer burn on refrigerated poultry and outlines a plan of research to determine means for its prevention.

Sex differentiation in day-old ducklings, P. J. SERFONTEIN (*Farming in So. Africa, 10 (1935), No. 113, pp. 349, 350, figs. 2*).—A detailed description of the method of examining ducklings for sex determination immediately after removal from the incubator is presented. It is stated that on opening the cloaca of the male, there is a distinctly visible organ which is absent in the female. The opinion is expressed that a person after examining 25 individuals should be able to determine sex with 100 percent accuracy.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle in Florida], R. B. BECKER, W. M. NEAL, P. T. D. ARNOLD, and A. L. SHEALY (*Florida Sta. Rpt. 1935, pp. 50, 51, 52, 53, 56*).—Data obtained in tests with dairy cattle are reported on deficiencies in feeds used in cattle rations, the ensilability of *Crotalaria intermedia*, Napier grass, sorghum, and sugarcane, the digestibility coefficients and feeding value of dried grapefruit refuse, and the feeding value of crotalarias.

[Investigations with dairy cattle and dairy products in Idaho], D. R. THEOPHILUS (*Idaho Sta. Bul. 220 (1936), pp. 26–28, 29, 30, fig. 1*).—Results are given from studies with dairy cattle on the continuous use of proved sires for maintaining high production, the value of breeding efficiency to dairymen, the difference between the Eckles standard and the observed weight and height of Holstein females in Idaho, the feed utilizing efficiency of high producing Holstein cows, and variations in the solids-not-fat content of the milk of individual cows within the Holstein and Jersey breeds.

In tests with dairy products, information was obtained on the importance of thorough washing and sterilizing of the separator in producing good quality cream, and the relationship between the extraneous matter in cream and the amount of extraneous matter in the finished butter.

[Investigations with dairy cattle and in dairy production in Michigan], E. L. ANTHONY and E. D. DEVEREUX (*Michigan Sta. Rpt. 1935, pp. 177, 178, 214, 215*).—The results obtained in studies with dairy cattle are reported on the vitamin D content of corn silage and the vitamin D requirement of growing calves, the value of alfalfa hay in the ration of dairy cattle, and the effect of supplementing a basic ration of low phosphorus alfalfa, corn silage, and corn with bonemeal on growth, reproduction, and milk production of dairy cattle.

Studies with dairy products produced data on indophenol substitutes for methylene blue in the reduction test, synthetic media for bromothymol blue test, a sanitary survey of the milk produced in the Lansing milkshed, the homogenization of milk, the effect of heat on certain chemical and physical properties of milk, the effect of sugar beet tops on the flavor of milk, and influence of source of fat and serum solids on the quality and overrun of ice cream.

[Investigations with dairy cattle by the Montana Station] (*Montana Sta. Rpt. 1934, pp. 49, 50, 71, 72*).—Studies with dairy cattle produced results on the use of rye as a grain feed for dairy cattle, and at the Huntley Substation on the value of high quality roughages for economical milk and butterfat production, cutting pasture grasses for soiling and silage, the use of Reed canary grass as a pasture crop, the use of an open-shed type barn for dairy cattle, and securing superior germ plasm in dairy cattle.

[Investigations with dairy cattle and dairy products in New Jersey] (*New Jersey Stas. Rpt. 1935, pp. 6, 7, 25–32, 33, 34, 35, 36*).—Information obtained in studies with dairy cattle are reported on the effect of processing on the carotene content of alfalfa hay, analyses of alfalfa-timothy hay silage, inbreeding and outcrossing Holstein dairy cattle in establishing genetic factors for high milk and fat production, color pigmentation in the skin and milk of Guernsey dairy cattle, methods of winter feeding of dairy heifers and their relationship to growth on summer pasture, the value in a dairy ration of dehydrated molasses, grass silage, dehydrated roughage, and animal byproducts, the yield of green grass for ensilling from timothy sod treated with varying applications of calcium cyanamide, and grass silage as a means of growing more feed units.

In studies with dairy products results were obtained in tests on the effects of certain fatty acids and their triglycerides on the processing of dairy products, and methods employed in standardizing milk.

[Experiments with dairy cattle in South Dakota], T. M. Olson (*South Dakota Sta. Rpt. 1935, pp. 24–26*).—Results obtained in tests with dairy cattle are reported on a comparison of sweetclover, alfalfa, Sudan grass, and permanent pasture mixtures under South Dakota conditions; the influence of roughage on the vitamin D potency of milk; the effect of tankage on flavor in milk; the effect of breeding on the vitamin D potency of milk; effect of sunlight on the milk of dairy cows; and variations in the calcium and phosphorus content of cows' milk during the lactation period.

Molasses hay silage, C. B. Bender, H. H. Tucker, W. C. Krueger, K. O. Pfau, and A. S. Fox (*Jour. Dairy Sci., 19 (1936), No. 2, pp. 137–146, figs. 5*).—This contribution from the New Jersey Experiment Stations deals with the preparation of silage from legumes and mixed grasses of both high and low moisture content, 40 lb. of molasses per ton being added in each case. Special note was made of temperatures developed during the ensilling process by means of thermocouples placed at various levels and distances from the walls as the the silo was filled.

The low moisture silage reached a maximum temperature of 141° F. on the seventh day and continued to rise during the latter part of the storage period, reaching a maximum of 157.7°. The temperature of the high moisture silage as a whole remained well under 100°, with 103° the maximum recorded. On opening the silo the low moisture silage was found practically unfit for feeding, ranging from a very dry moldy condition near the edge to black and charred material near the center of the lower section. Practically all lactic acid type bacteria had been destroyed. The high moisture silage was in excellent condition, with no signs of burning or rotting, and showed very small loss of nutrients during the ensilling process.

Effects of uncomplicated phosphorus deficiency on estrous cycle, reproduction, and composition of tissues of mature dairy cows, C. H. Eckles, L. S. Palmer, T. W. Gullickson, C. P. Fitch, W. L. Boyd, L. Bishop, and J. W. Nelson (*Cornell Vet., 25 (1935), No. 1, pp. 22–43; abs. in Minnesota Sta. Rpt. 1935, p. 39*).—Continuing the study of phosphorus deficiency (E. S. R.,

70, p. 233), this experiment was designed to determine the effect of such deficiency upon the oestrous cycle of cows. The ration used was designed to provide an adequate supply of all minerals except phosphorus. The animals were kept in a barn and exercised in a dry lot free of vegetation. Careful watch was kept for physiological evidences or external symptoms of heat. In addition a careful physical examination was made of the reproductive organs at intervals of 30 days.

It was found that uncomplicated phosphorus deficiency could be experimentally produced in mature dairy cows and continued for two or three years without causing abnormal oestrum. The condition did appear to reduce breeding efficiency. It is concluded that the disturbances in oestrum and the low calf crop among cattle in phosphorus-deficient areas were probably due to the complicated nutritive deficiencies prevalent under such conditions.

The effect of ingested cod liver oil, shark liver oil, and salmon oil upon the composition of the blood and milk of lactating cows, C. M. McCAY L. A. MAYNARD, ET AL. (*Jour. Biol. Chem., 109 (1935), No. 1, pp. 29–37, fig. 1*).—In the first of two experiments from the [New York] Cornell Experiment Station, two cows were fed for 4 weeks on normal herd rations, then for 4 weeks on the same ration plus 168 cc of cod-liver oil daily. No relation was noted between oil feeding and the composition of the blood other than an increase in the iodine number of the plasma lipids. Total lipids in mammary plasma were consistently lower than in jugular plasma, indicating that the gland removes lipids in some form from the blood. There was a rapid drop in milk fat during the first week of cod-liver oil feeding and the minimum was reached during the second week, with the fat content returning to normal within 2 weeks after oil feeding was discontinued.

In the second trial five cows were fed for alternate 2-week periods with and without oil in the ration to determine the effect of straight cod-liver oil, the saponifiable and nonsaponifiable fractions of cod-liver oil, shark oil, and salmon oil on the composition of milk. The usual lowering of milk fat during the cod-liver oil period, both under dry lot and pasture conditions, was noted. The effect of both the shark and salmon oil was much less and very inconsistent, indicating that perhaps they do not act like cod-liver oil. The nonsaponifiable fraction of cod-liver oil had no effect on milk fat, while the saponifiable fraction seemed to carry the injurious substance. It is suggested that the fraction causing muscle lesions in Herbivora may be the same as that which depressed fat secretion.

The decrease in the lactose content of milk following the production of artificial hypoglucemia, W. R. BROWN, W. E. PETERSEN, and R. A. GORTNER (*Jour. Dairy Sci., 19 (1936), No. 2, pp. 147–154, figs. 3*).—In this experiment at the Minnesota Experiment Station, artificial hypoglucemia was produced in dairy cows through repeated intravenous injections of insulin. The results of three trials are presented. From 800 to 1,000 units of insulin were used, the number of injections varying from 2 to 5.

Each case resulted in a marked hypoglucemia, followed by a decrease in the lactose content of the milk in each instance. No paresis or coma was noted in any of the animals. Milk samples were taken at frequent intervals to follow the trend of lactose synthesis. In general, the milk sugar curves followed the blood sugar curves by approximately 1 hr., and when correlated on this basis the correlation was 0.6084 ± 0.19. A rise in lactose content of the milk was noted at about the normal evening milking period, which was probably due to an outpouring of stored milk secreted before the onset of the experimental hypoglucemia.

Soybean flour as a substitute for cow's milk in feeding dairy calves, L. SHOPTAW (*Jour. Dairy Sci., 19 (1936), No. 2, pp. 95–99, figs. 2*).—In this study at the [Oklahoma] Panhandle Experiment Station, soybean flour was fed as a gruel to a group of four dairy calves for 70 days in comparison with a similar check group fed whole milk and skim milk. The calves were 25 days of age at the beginning of the trial. Both groups had free access to both grain mixture and alfalfa hay.

The soybean flour group consumed less of the liquid feed, more grain, and less hay than the milk-fed group, was less thrifty, subject to considerable diarrhea, and did not relish the soybean milk at the start. They gained 0.9 lb. daily in weight and a total of 4.37 in. in height at withers during the trial as against 1.24 lb. and 4.94 in. for the milk-fed calves.

Estimating the weights of dairy cows from heart-girth measurements, J. F. KENDRICK and J. B. PARKER (*U. S. Dept. Agr., Bur. Dairy Indus., 1936, BDIM–695, pp. 2*).—A table is presented for estimating the live weight of dairy animals from heart-girth measurements, based on a study of 1,721 actual weights and heart-girth measurements of Holstein and Jersey cattle.

Information on dairy herd-improvement associations, J. F. KENDRICK (*U. S. Dept. Agr., Bur. Dairy Indus., 1936, BDIM–692, pp. 10*).—A list of 43 questions and answers pertaining to dairy herd improvement associations is presented.

DHIA proved-sire list, I, compiled by J. F. KENDRICK (*U. S. Dept. Agr., Bur. Dairy Indus., 1936, BDIM–706, pp. 58*).—This is a list of 385 dairy sires proved for production in Dairy Herd Improvement Association work in the various States, along with the average mature equivalent production of the proving daughters and of their respective dams.

Organizing cooperative dairy bull associations, J. G. WINKJER (*U. S. Dept. Agr., Bur. Dairy Indus., 1936, BDIM–691, pp. 8*).—Suggestions are made regarding the plan of organization, the selection of bulls, and the operation of cooperative bull associations.

Milk goats coming into their own, J. C. MARQUARDT (*Farm Res. [New York State Sta.], 2 (1936), No. 4, p. 12, fig. 1*).—The present status of the milk goat industry and the attempts that are being made to improve the quality of goat milk are discussed.

Investigations on the milk of a typical herd of Shorthorn cows, II, J. GOLDING, J. MACKINTOSH, and E. C. V. MATTICK (*Jour. Dairy Res. [London], 6 (1935), No. 1, pp. 6–25, figs. 2*).—Continuing this study (E. S. R., 70, p. 520), summaries are presented covering the fourth and fifth years of the investigation. Special emphasis is laid on the unusual composition of milk noted during the drought in the summer of 1933, especially the abnormal fall in solids-not-fat, lower values for formol titration and phosphorus, and a longer time for rennet coagulation. Daily records covering this period are presented.

The analysis of weekly composite samples showed relatively high values for titratable acidity, formol titration, ash, calcium, and phosphorus from October to February, followed by a general decrease during the summer months. Determinations of pH values and freezing point showed little seasonal variation. The possibility of a close association between nonfatty solids and phosphorus content is suggested.

Seasonal variation of the percentage butterfat content of milk: An examination of the results of certain individual cow tests, C. D. OXLEY (*Jour. Dairy Res. [London], 6 (1935), No. 1, pp. 1–5*).—A statistical analysis, including the means and standard deviation of the butterfat percentage of approximately 3,200 milk samples and representing both morning and evening

milkings for each of the four quarters of the year, is presented, with a discussion of the probable source of error due to the nature of the samples.

It is noted that the means of the afternoon samples for July–September and for October–December are significantly higher than for January–March, but not significantly higher than for April–June, nor is the latter higher than for January–March. In the case of the morning samples the means for July–September and for October–December are significantly higher than for the other two seasons, with little difference noted between the January–March and April–June quarters.

The relation of the amino nitrogen content to quality of cream and butter, D. H. JACOBSEN (*Jour. Dairy Sci., 19 (1936), No. 2, pp. 125–136, fig. 1*).—In experiments at the South Dakota Experiment Station, 27 churnings were made from lots of cream graded as second grade sour, first grade sour, and fresh sweet cream. Samples of cream and buttermilk were analyzed for amino nitrogen at churning time, and butter samples were similarly analyzed and also scored for quality when fresh and after 1, 3, and 6 mo. in storage.

Based on acidity and flavor of cream, the percentage of total nitrogen occurring as amino nitrogen increased as the quality of cream decreased. In general, cream and butter containing the higher percentage of amino nitrogen gave lower butter scores, although considerable overlapping of grades was noted. Classification of churnings on the basis of amino nitrogen content of cream alone failed to determine satisfactory butter flavor grades. The lowest score of butter showed the highest percentage of total nitrogen occurring as amino nitrogen, both fresh and at each stage of storage. Apparently the amino nitrogen content may be of aid in cream grading only when used in combination with flavor and acidity tests.

Babcock testing and other methods of analyzing dairy products, L. K. CROWE (*Nebraska Sta. Circ. 53 (1936), pp. 40, figs. 17*).—This publication contains information about and directions for using the Babcock and other methods for testing milk, cream, skim milk, buttermilk, whey, butter, and other dairy products for their principal constituents. Typical problems in dairy arithmetic are included.

Determining cleanliness of milk supplies, M. W. YALE (*Farm Res. [New York State Sta.], 2 (1936), No. 4, pp. 5, 10*).—In this article the author describes some of the methods used in examining milk for cleanliness and discusses the limitations of the methods.

The evaluation of the germicidal potency of chlorine compounds, I, II, C. K. JOHNS (*Sci. Agr., 14 (1934), No. 11, pp. 585–607, fig. 1, Fr. abs., p. 607; 15 (1934), No. 4, pp. 218–227, figs. 4, Fr. abs., p. 227*).—This investigation was carried on at the Central Experimental Farm, Ottawa.

I. *Hypochlorites.*—In the first study results are presented on several methods for evaluating the germicidal potency of hypochlorite sterilizing products. Two new test methods, an indicator test for pH, and a microscopic slide biological test were developed, both of which are considered promising. Certain discrepancies are noted which occur in rating the various concentrations by different test methods, and which apparently are due to the differences in the buffer capacities of the product. Most accurate results are obtained by testing freshly prepared solutions.

The results indicate that the influence of the pH of the solution is greater than the concentration of available chlorine, particularly in dilute solutions, in determining its germicidal potency.

II. *Chloramine-T products.*—The germicidal potency of five commercial chloramine-T products and of U. S. P. chloramine-T in varying concentrations

was determined. Within a range of 2,000 to 25 p. p. m., each of the commercial products showed a gradual decline in germicidal activity on dilution, whereas the U. S. P. product behaved differently, showing decreased germicidal potency as the concentration was reduced from 2,000 to 1,000 p. p. m., then showing increased activity as the concentration was further reduced to 200 p. p. m., falling off again beyond that point.

Note is made of an unusual pH reaction of the commercial products studied, in that each became more alkaline on dilution with water having a slight acid reaction, while U. S. P. chloramine-T decreased in alkalinity on dilution, reacting similarly to hypochlorite solutions. This unusual reaction is attributed to the presence of sodium bicarbonate in the commercial product, and probably accounts for the difference in germicidal potency of the commercial and U. S. P. compounds.

A comparison of ten presumptive test media used in the detection of the Escherichia-Aerobacter group in milk, M. A. FARRELL (*Jour. Bact., 30 (1935), No. 6, p. 654*).—In an investigation by the Pennsylvania Experiment Station of 10 of the better-known presumptive test media proposed for use in water and milk analysis, brilliant-green lactose bile, fuchsin lactose broth, and methylene-blue brom-cresol-purple broth proved superior, detecting the *Escherichia-Aerobacter* group of bacteria in milk in 53 percent of the samples examined. The remaining seven media were 20 percent less efficient in the detection of this group.

Concerning the habitat of Streptococcus lactis, P. STARK and J. M. SHERMAN (*Jour. Bact., 30 (1935), No. 6, pp. 639–646*).—In this study at the [New York] Cornell Experiment Station, *S. lactis* was consistently isolated from certain plant sources, including fresh corn (grain and silks) and dried navy beans. It was also obtained from cabbage, head lettuce, garden peas, and wheat middlings, though with some difficulty. When these isolated strains were tested with respect to their actions on arabinose, xylose, sucrose, and mannitol, they were found to correspond quite closely with the strains from milk, although wide variations were noted in the behavior of the various strains from this small group.

The organism was not isolated from all plant sources examined, neither was it found in the mouths or throats of cows, bovine feces, human feces, or in soil. It is demonstrated that *S. lactis* does occur on plants, and it is suggested that they may represent the natural habitat of the organism.

Types of Oospora found in butter, C. M. SORENSEN and E. H. PARFITT (*Jour. Bact., 31 (1936), No. 1, pp. 86, 87*).—In examining acidulated potato dextrose agar plates of 600 samples of pasteurized commercial sour cream butter at the Indiana Experiment Station, a difference was noted in the appearance of the *Oospora* colonies that grew on these plates.

From cultures made from those colonies differing in appearance apparently eight different varieties were obtained, all of which could be characterized as *O. lactis*. Significant differences were found within these cultures as to caseolysis, lipolysis of milk and tributyrin, growth rates, optimum temperature, and majority thermal death point, also in their production of caseolytic and lipolytic enzymes.

The relation of Oospora lactis to the keeping quality of butter, O. H. AUSH and H. MACY (*Amer. Creamery and Poultry Prod. Rev., 79 (1934), No. 6, pp. 190–194; abs. in Minnesota Sta. Rpt. 1935, p. 35*).—A study was made at the Minnesota Experiment Station of the effect of *O. lactis* on unsalted butter. On the basis of their activity or rapidity of growth, seven varieties of the fungus were selected from approximately 100 cultures isolated from different grades of commercial butter for use in this study.

The fungus grew well in unsalted butter stored at 10° C. (50° F.), whether the butter was made from sweet, sour, raw, pasteurized, or autoclaved cream. There was no direct correlation between the fungus count and the quality of the butter after storage. The temperature and period of incubation of infected cream did not consistently influence the fungus or the score of the butter after storage. Whether grown in sweet or sour cream, *O. lactis* was not a factor in the deterioration of butter made from such infected cream. No correlation existed between the fungus count and acidity of the cream, with the score of the butter after storage, or between the acidity of the cream and the score of the butter after storage. The fungus was capable of destroying the substances responsible for the flavor of fine starter butter.

Butter worked with *O. lactis*-infected equipment or inoculated during the working process and stored at —23° had a higher fungus count than butter made from infected cream. Pasteurizing temperatures above 60° for 30 min. or 82° by the flash method and autoclaving at 118° for 30 min. destroyed the fungus in cream, but the keeping quality of the butter was not materially improved. The fungus count of salted butter decreased with increasing brine concentrations, although it remained relatively high even at 20-percent concentration. Salt improved the keeping quality of *Oospora*-infected butter, and a 1.5-percent concentration was as effective as 3 percent. Butter stored at —23° had better keeping qualities than that stored at either 2° or 10°. The seven cultures of *O lactis* studied, whether grown alone or in combination, were ineffective in influencing the keeping quality of autoclaved sweet cream or storage butter, except that the starter flavor was destroyed.

Effect of temperature, salt, and acidity on growth of mould (Oospora lactis), H. MACY and A. E. ANDERSON (*Natl. Butter and Cheese Jour., 25 (1934), No. 22, pp. 28, 29; abs. in Minnesota Sta. Rpt. 1935, p. 31*).—The Minnesota Experiment Station made a study of the effects of salt concentration, temperature, and acidity on the growth of seven cultures of *O. lactis* on whey agar and in buttermilk.

Growth was extensive in the controls on all media at 20° C. (68° F.), less luxuriant at 10° and 2°, and entirely checked at —23°. Except when the pH of whey agar was low, there was no permanent effect on the viability of cultures due to low temperatures. The growth on whey agar was affected when the salt concentration exceeded 1 percent and was entirely checked at 10 percent. On buttermilk growth was usually retarded at a salt concentration above 2.5 percent and stopped at 10 percent. The degree of acidity did not in itself have a very marked effect on the extent of growth. The combined effects of high salt concentration and low temperatures and/or pH concentration were noticeable.

A method of preparing churned cultured buttermilk, C. L. ROADHOUSE and E. E. BROWN (*California Sta. Circ. 339 (1936), pp. 12, figs. 4*).—Methods for preparing starters, the handling of milk and cream, and the churning process are discussed. Suggestions regarding cooling, bottling and storage, delivery, and care of equipment are also presented.

French contributions to the art of cheese-making, R. S. BREED and C. D. KELLY (*Farm Res. [New York State Sta.], 2 (1936), No. 4, pp. 3, 9, figs. 4*).—Continuing this series of articles (E. S. R., 75, p. 250), the types of cheeses produced in France are described.

Methods of making cottage cheese on the farm, L. H. BURGWALD (*Ohio Sta. Bimo. Bul. 181 (1936), pp. 92, 93*).—Processes are described.

The age thickening of sweetened condensed milk.—IV, The effect of salts, V. C. STEBNITZ and H. H. SOMMER (*Jour. Dairy Sci., 19 (1936), No. 2, pp.*

101–115, fig. 1).—Continuing this series of studies (E. S. R., 75, p. 250), data are presented on the effect of adding certain salts to both stable and unstable milks before and after condensing as regards the stability of the finished product toward age thickening.

The results indicate that stable condensed milk cannot be further stabilized by the addition of sodium citrate, disodium phosphate, or calcium acetate. The addition of sodium citrate to unstable milk either before or after condensing had a pronounced stabilizing effect, while disodium phosphate added to unstable milk before condensing had only a slight stabilizing effect. The addition of calcium acetate or disodium phosphate after condensing caused a rapid thickening. Results are presented to show that there is no correlation between the alcohol test and the stability of sweetened condensed milk toward age thickening.

Using frozen cherries in cherry ice cream, J. C. HENING (*Ice Cream Trade Jour., 31 (1935), No. 11, p. 16*).—In this brief report from the New York State Experiment Station it was demonstrated that common varieties of sour cherries, when packed in the ratio of 4 parts of cherries to 1 part of sugar and frozen, could be used later to produce a very satisfactory cherry ice cream. Additional sugar was added as the cherries were thawed, and the cherries and sirup were added to the ice cream mix early in the freezing period in the ratio of 30 parts of cherries to 70 parts of mix. This high percentage seemed desirable, due to the mild flavor of the cherry.

VETERINARY MEDICINE

Treatise on exotic veterinary and comparative pathology.—II, Microbe diseases, G. CURASSON (*Traité pathologie exotique vétérinaire et comparée.—II, Maladies microbiennes. Paris: Vigot Bros., 1936, pp. 689*).—The second of the three volumes of this work (E. S. R., 75, p. 102) deals with the visible microbe (including fungus) diseases. Bibliographical lists of references accompany the accounts of the several diseases.

[Report of work in animal pathology by the Florida Station] (*Florida Sta. Rpt. 1935, pp. 50, 55, 56, 58, 59, 129*).—The work of the year with animal diseases referred to (E. S. R., 73, p. 236) includes the etiology of fowl paralysis and leukemia, by M. W. Emmel, reports relating to which have been noted (E. S. R., 74, pp. 700, 856; 75, p. 547); investigations of hemorrhagic septicemia in cattle and swine, by D. A. Sanders; effect of feeding colon organisms and dried whey on the bacterial flora of baby chicks affected with pullorum disease, by Emmel; a study of plants poisonous to livestock in Florida, by Sanders, Emmel, and E. West, including *Cassia occidentalis*, *Crotalaria spectabilis*, cocklebur, tungseed meal, and *Glottidium vesicarium*; and cattle parasites under Everglades conditions, by R. W. Kidder.

[Report of work in animal pathology by the Idaho Station] (*Idaho Sta. Bul. 220 (1936), pp. 22–25, 45–47, fig. 1*).—The work of the year in animal pathology referred to (E. S. R., 74, p. 99) includes further work with grubs in the head of sheep (sheep batfly), tests for pullorum disease control, cure of foul sheath in rams by the use of copper sulfate, udder infections, transmission of paratyphoid in turkeys through the eggs, flock resistance to fowl paralysis, and a new disease of turkeys due to a paratyphoid organism of the *Salmonella aertrycke* type.

[Report of work in animal pathology, parasitology, and bacteriology by the Michigan Station] (*Michigan Sta. Rpt. 1935, pp. 162–176, 177, 179, 180, 180–201, figs. 2*).—The work of the year reported upon (E. S. R., 73, p. 536)

relates to Bang's disease control and horse parasite control, both by B. J. Killham; bromothymol blue broth in the detection of mastitis streptococci, by E. D. Devereux; mastitis studies, by C. S. Bryan; vaccination of cattle against Bang's disease, by I. F. Huddleson; coccidiosis control experiments and control of intestinal worms of poultry, both by W. L. Chandler; tapeworm infestation, coccidiosis immunity work, the effect of chronic coccidiosis on the growth, production, and mortality of laying pullets, roup vaccination, infectious laryngotracheitis vaccination, and autopsies in connection with work in avian pathology, all by H. J. Stafseth; and a note on the influence of high frequency alternating current on animals, by H. T. Graham and F. W. Fabian.

[Report of work in veterinary medicine by the Montana Station] (*Montana Sta. Rpt. 1934, pp. 52–54*).—The work of the year is briefly referred to, with particular reference to control of infectious abortion, foot rot of sheep, arthritis in lambs, and acute diarrhea in lambs.

[Work in animal pathology by the New Jersey Stations] (New Jersey *Stas. Rpt. 1935, pp. 34, 77, 78*).—The work of the year referred to (E. S. R., 73, p. 236) includes a study of the methods of controlling Bang's disease, infectious laryngotracheitis of the fowl, paratyphoid infection of pigeons, fowl paralysis, and swine erysipelas infection in turkeys.

[Work in animal pathology by the South Dakota Station] (*South Dakota Sta. Rpt. 1935, pp. 18, 19–22, 35–45, 47, 48*).—The work of the year referred to (E. S. R., 73, p. 236) includes a chenopodium experiment in worming pigs, earlier studies of which by LeBlanc, Wright, and Taylor have been noted (E. S. R., 71, p. 537); studies of so-called "alkali disease" due to selenium intoxication, by K. W. Franke; pharmaceutical studies of chenopodium, by F. J. LeBlanc; and the progress of work with hemorrhagic septicemia, by C. C. Lipp.

Toxicity tests on African rue (Peganum harmala L.), W. L. Black and K. W. Parker (*New Mexico Sta. Bul. 240 (1936), pp. 14, figs. 8*).—Livestock losses in a localized area a short distance east of Deming, N. Mex., in the early spring months of 1934 and 1935 led to studies of the palatability and possible toxicity to cattle and sheep of *P. harmala*, suspected of being the cause.

The plant was shown to be unpalatable, being eaten by cattle and sheep only when they are in a starving condition. The unpalatability was reduced by drying, but cattle and sheep refused to eat hay made of it when kept before them in a feed lot for several days.

The amounts fed to the animals in the experiment gave no indication that consumption by cattle or sheep is detrimental to their health. "A dosage of 44.5 g (1.57 oz.) of the seed per day over a period of 4 days is apparently harmless to an 89-lb. sheep. A dosage of 160.3 g per day of the mature leaves and stems over a period of 26 days was likewise harmless to sheep weighing 77 and 63 lb. A dosage of 136.2 g per day of the young leaves and stems without seed pods continued over a period of 20 days was harmless to sheep weighing 59 and 89 lb. Grazing for a period of 33 days in a pasture containing no other vegetation failed to produce any noticeable effects upon sheep.

An average daily dose of 250.6 g of mature seed fed to a 780-lb. cow for a period of 29 days failed to produce unfavorable symptoms in the animal. An average daily feeding of 667.6 g of mature leaves and stems fed to an 890-lb. cow for a period of 26 days had no effect upon the animal, and an average daily dose of 406 g of young leaves and stems without seed pods fed to an 880-lb. cow for a period of 15 days produced no ill effects. A test in which the animal was confined for a period of 33 days to a pasture with no other

vegetation present and with the supplemental feeding of a daily average of 568 g of mature leaves and stems, including seed pods, over a period of 24 days failed to produce any noticeable effects on a 760-lb. cow.

Organ specificity of the parasite Eimeria tenella, C. A. HERRICK (*Jour. Parasitol., 22 (1936), No. 2, pp. 226, 227*).—It is considered apparent from the studies conducted that (1) "the sporozoites of *E. tenella* localized in the epithelium of a cecal pouch through which all intestinal material had passed for a period of 4 days with all the resulting changes in physiology, and (2) the sporozoites escaped from the oocysts and established themselves in the normal and translocated cecal pouches after passing through only the anterior half of the duodenal loop of the chicken."

The Australian epidemic of encephalomyelitis (X-disease), J. R. PERDRAU (*Jour. Path. and Bact., 42 (1936), No. 1, pp. 59–65, pls. 3*).—The Australian X disease studied by Cleland et al. (E. S. R., 41, p. 876) was caused by a virus with characteristics so closely resembling those of the virus of louping ill that differentiation between them on the evidence now available is well-nigh impossible, but no claim is made that they are one and the same virus.

Observations upon the migrations and pathogenesis of Gasterophilus larvae, D. E. FAULKNER and A. A. KINGSCOTE (*Jour. Parasitol., 22 (1936), No. 2, p. 228*).—The authors record the presence of the larvae of *Gasterophilus* in the lumen of the esophagus, their absence in submucous and periesophageal tissues, and the occurrence of a marked edema in the gastric submucosa.

Inapparent (subclinical) infection of the rat with louping-ill virus, F. M. BURNET (*Jour. Path. and Bact., 42 (1936), No. 1, pp. 213–225*).—In the work reported rats have shown no manifest evidence of infection after intranasal inoculation with louping ill virus, but the virus regularly appears and apparently multiplies in the olfactory bulbs. While it has not been possible to provide proof that multiplication of louping ill virus in rats takes place only within the cells of the nervous system, all available data support this inference.

A sequel to a public health ruling concerning streptococcic mastitis, C. S. BRYAN and G. J. TURNEY (*Amer. Jour. Pub. Health, 26 (1936), No. 5, pp. 517–520*).—This contribution from the Michigan Experiment Station reports upon the outcome of control work with streptococcic mastitis in dairy herds conducted by the city of Lansing in an effort to increase the quality of raw milk and suppress any possible health hazard. The mastitis-affected animals were removed from herds supplying milk to the city, and herd retests are being made every 6 mo. The elimination of infected cows has resulted in a marked decline in the herd wastage and the production of a higher quality of milk.

Mastitis from the manufacturers' and distributors' viewpoint, F. B. HADLEY (*Vet. Med., 31 (1936), No. 5, pp. 207–209*).—This is a contribution from the Wisconsin Experiment Station.

A note on the influence of culture media on the isolation of Pasteurella from equine cerebral tissue of artificially inoculated horses, R. GRAHAM (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 59–64, fig. 1*).—The results obtained in cultural studies on equine cerebral tissues taken from horses immediately following death from artificial *Pasteurella* inoculation suggest that the type of media selected for direct propagation of *Pasteurella* strains is important in accurately appraising the presence or absence of a cerebral *Pasteurella* infection of the equine encephalon. Different types of liquid media discussed, upon being inoculated with bits of cerebral tissue, yielded positive results in all three horses, while the same cerebral tissue specimens heavily seeded on plain agar and gentian violet-agar plates proved negative.

An epidemic of Pasteurella infection in a guinea-pig stock, J. WRIGHT (*Jour. Path. and Bact., 42 (1936), No. 1, pp. 209–212*).—An account is given of an epidemic of fibrinopurulent serositis in a guinea pig colony caused by a member of the *P. septica* group.

Criteria for the accurate classification of the rickettsial diseases (rickettsioses) and of their etiological agents, H. PINKERTON (*Parasitology, 28 (1936), No. 2, pp. 172–189, pls. 2*).—Morphological, histopathological, and immunological studies of seven strains of rickettsial disease have led to the conclusion that they represent two widely separated groups for which typhus and spotted fever seem the most logical names.

"Diseases of the spotted fever group are carried by ticks (Arachnoidea) and characterized by distinctive histopathological lesions—thrombonecrosis of arterioles and venules, with micro-organisms of definite and characteristic morphology, invading smooth muscle cells, as well as endothelium, mesothelium, and macrophages. Tissue culture studies show massive invasion and distention of cell nuclei, while cytoplasmic invasion of host cells is relatively sparse.

"Diseases of the typhus group are carried by lice and fleas (Insecta) and characterized by the facts that the intracellular parasite which causes them invades only endothelium and mesothelium, distends the cytoplasm of its host cells without ever invading nuclei, and in guinea pigs causes only proliferative endangeitis without thrombonecrosis.

"In the spotted fever tick, organisms are intranuclear as well as intracytoplasmic, invade nearly all types of tissue, and are transmitted hereditarily. In typhus-infected lice and fleas, organisms are intracytoplasmic only, infect only the lining cells of the gut, and are not transmitted hereditarily."

Staphylococci from animals, with particular reference to toxin production, F. C. MINETT (*Jour. Path. and Bact., 42 (1936), No. 1, pp. 247–263*).—The author has found the production of β toxin to be a characteristic feature of hemolytic staphylococci from animals. "Thus out of 97 strains from various animal sources, mostly cow's milk, only 5 failed to form recognizable amounts of β toxin. Ten strains, including 8 from dogs, produced β toxin and only very small or undetectable amounts of α toxin. The staphylococci from dogs were also distinguished by their greater proteolytic power in culture. The α unitage of cow serum is generally below 7.0 and the β unitage generally 0.45y or less."

Turning sickness, a protozoan encephalitis of cattle in Uganda: Its relationship with East Coast fever, R. W. M. METTAM and J. CARMICHAEL (*Parasitology, 28 (1936), No. 2, pp. 254–283, pl. 1*).—A description is given of this specific disease which occurs sporadically in the East Coast fever areas of eastern equatorial Africa. "Clinically, acute cases are characterized by peculiar nervous symptoms, absence of fever, and blindness. Death occurs in most cases within 2 to 21 days of the onset of illness. Chronic cases are encountered from time to time and may survive up to 6 mo. The disease is widespread in Uganda. It affects cattle of both sexes and all breeds and is commonest in young stock between 6 mo. and 2 yr. of age. It has, however, been observed in older animals.

"Pathologically, in acute cases petechial hemorrhages or extravasations are found in various parts of the brain and meninges. Generally the hemorrhages are small and do not seriously injure the adjacent brain tissue. In some cases the extravasations are responsible for a considerable amount of damage. Microscopic examination shows that the brain lesions are due to extensive embolism of cerebral vessels. The lymphocytes which form these emboli contain in their cytoplasm protozoan bodies indistinguishable in structure from the schizonts

of the genus *Theileria*. These bodies occur in great numbers in the brain but are extremely rare or absent in the lymphocytes of other parts of the body. In chronic cases the hemorrhages have been absorbed, but the brain is permanently damaged by replacement changes and by the appearance of small cysts or cavities which contain a citron colored fluid. These cavities when numerous seriously disorganize certain parts of the brain.

"The disease has not yet been transmitted experimentally, and its connection with the theileriases is still uncertain. However, much evidence has been collected to show that cases of turning sickness have been infected with East Coast fever some time previously, generally on an average of 6–8 mo. The possible relationship between turning sickness and East Coast fever is discussed at some length."

The role of the rat flea in the transmission of typhus, G. COVELL and D. R. MEHTA (*Indian Jour. Med. Res., 23 (1936), No. 4, pp. 921–927, fig. 1*).—In a study of typhus in the Simla Hills a strain was recovered from rat fleas collected from wild rats which has been maintained in guinea pigs for 17 generations. "A strain of typhus originally derived from the brains of wild rats has been transmitted from an experimentally infected white rat to a normal white rat by means of the rat flea, *Xenopsylla cheopis*. The clinical and serological reactions produced in laboratory animals by infection with the strain were unaltered by its passage through the flea. Rickettsiae morphologically indistinguishable from those observed in laboratory animals inoculated with passage virus have been demonstrated in fleas fed on experimentally infected white rats. Our results indicate that there is a great multiplication of rickettsiae in *X. cheopis*, thus confirming the observations of workers in other countries."

The effect on rodents of Bacillus typhi murium cultivated in rye grain by a new method used at the Pasteur Institute as compared with the virus from ampoules [trans. title], A. CHAPPELLIER (*Ann. Épiphyt. et Phytogénét., n. ser., 1 (1934–35), pp. 341–348, figs. 4*).—The author has found *B. typhi murium* as cultivated in rye grain by a new method emp'oyed at the Pasteur Institute of Paris to be quite generally consumed by 10 species of rodents tested and often in the presence of their natural food. Two species tested appeared to be resistant to the action of the organism.

The cercaricidal action of normal serums, J. T. CULBERTSON (*Jour. Parasitol., 22 (1936), No. 2, pp. 111–125*).—A description is given of the antagonistic action of the normal serum of vertebrates against larval trematodes (cercariae), which action is manifested by the serum of representatives of all classes of vertebrates. "A considerable number of species of cercariae belonging to different groups have been tested and found susceptible to the cercaricidal action of the normal serums. The substance in the serum responsible for the cercaricidal effect is highly labile, being readily destroyed by heat or by desiccation and quickly lost in storage. It can be removed from the serum by absorption with a dry mass of either cercariae or bacteria. The alexin of the fresh serum is fixed during the process of absorption of the cercaricidal power by these substances. Agencies which destroy specifically the several known components of alexin also destroy at the same time the cercaricidal power of the serum.

"It is possible that with further work the test for cercaricidal action of serum may aid in determining potential hosts of cercariae in trematode life histories. The relationship of the cercaricidal action to some other antagonistic properties of serum and the limited possibility of its development as a response to specific immunization are briefly discussed."

Granulomatous nasal swelling in a bovine, C. L. DAVIS and H. L. SHORTEN (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 91–96, figs. 4*).—This is a case

report of a 10-year-old Hereford cow, born and raised in Colorado under semi-range conditions, from which a species of *Helminthosporium* was isolated.

Transmission experiments with bovine malignant catarrh, R. DAUBNEY and J. R. HUDSON (*Jour. Compar. Path. and Ther., 49 (1936), No. 1, pp. 63–89, pl. 1, figs. 5*).—An account is given of transmission experiments with strains of malignant catarrh or snotsiekte from Kenya. Two strains, at least, proved to be transmissible.

Further investigations on the causal agent of bovine pleuropneumonia, F. F. TANG, H. WEI, and J. EDGAR (*Jour. Path. and Bact., 42 (1936), No. 1, pp. 45–51, pls. 2*).—In continuation of their earlier work (E. S. R., 73, p. 386), the authors present descriptions of two rare morphological elements of the bovine pleuropneumonia organism, namely, the ameboid and the giant ring forms. The organism was found to be resistant to ultraviolet rays and to the photodynamic action of methylene blue. It has been cultivated in the chorioallantoic membrane of chicken embryo. No inclusion bodies were found, but the organism could be reisolated. Pseudopleuropneumonia forms have been found in chicken embryos and in the blood of the hen, guinea pig, rabbit, goat, sheep, horse, and man, and are thought to be formed from the protoplasm of red blood corpuscles by some process of protein dispersion.

Cattle plague vaccine: Studies on glycerinised spleen pulp, S. C. J. BENNETT (*Jour. Compar. Path. and Ther., 49 (1936), No. 1, pp. 1–48*).—Studies of rinderpest vaccine are presented, with a list of 35 references to the literature.

The appearance of Trichomonas foetus, the cause of trichomonad abortion, in cattle in the Netherlands [trans. title], L. DE BLIECK and A. BOS (*Tijdschr. Diergeneesk., 63 (1936), No. 7, pp. 369–373; Ger. abs., p. 373*).—The authors record cases of pyometra in cattle in the Netherlands due to *T. foetus*.

Border pining in sheep, II, W. L. STEWART and A. P. PONSFORD (*Jour. Compar. Path. and Ther., 49 (1936), No. 1, pp. 49–62, fig. 1*).—This contribution reports upon further studies (E. S. R., 74, p. 544) in which nematode parasites of the subfamily Trichostrongylineae are shown to be the apparent cause of the main symptoms of acute pining, although the number of parasites present during the winter months are insufficient to account for the persistent anemia and emaciation characteristic of chronic pining. It is suggested that border pining is due to a combination or interaction of malnutrition and gastrointestinal parasitic infestation.

A note on the subject of Johne's disease in sheep [trans. title], THIERY and GETAS (*Bul. Acad. Vet. France, 8 (1935), No. 4, pp. 210–212; abs. in Vet. Rec., 16 (1936), No. 8, pp. 219, 220*).—In tests made of 107 head in a flock of sheep, in which 10 ewes had died from Johne's disease, 23 gave positive, 15 doubtful, and 69 negative reactions to johnin. In a second lot of 60 head tested, 22 gave positive reactions, 3 were doubtful, and 35 negative. Reference is made to records of occasional outbreaks of this disease in sheep in various countries since 1911.

Chronic progressive pneumonia of sheep, with particular reference to its etiology and transmission, G. T. CREECH and W. S. GOCHENOUR (*Jour. Agr. Res.* [*U. S.*], *52 (1936), No. 9, pp. 667–679, figs. 6*).—This is a report of work on the etiology and transmission of a fatal lung disease of sheep which has been recognized among the herds of the northwestern United States, especially in Montana, where it has been studied by Marsh and Cowdry at the Montana Experiment Station (E. S. R., 50, p. 481; 57, p. 673), and in Oregon, for at least two decades.

In the authors' investigations of the disease 23 naturally infected and 96 healthy sheep were used, the latter being experimentally exposed. A number

of the lung specimens from natural cases of the disease were cultured with negative results, whereas others yielded different types of organisms, none of which proved to be an etiological factor. The lesions of the disease are of the nature of a chronic catarrhal pneumonia. Only 4 of the 96 experimentally exposed sheep developed lesions similar in character to those seen in natural cases of chronic progressive pneumonia, which, in the opinion of the authors, were the result of experimental exposure. Definite evidence to this effect was lacking, however, because of the inability to reproduce similar lesions by further inoculations of diseased lung tissues from these 4 animals into other healthy sheep. The studies have failed to reveal any specific etiological factor of a bacterial nature or otherwise.

Note on the egg producing capacity of Cooperia curticei, a nematode parasitic in sheep, J. S. ANDREWS (*Jour. Parasitol., 22 (1936), No. 2, pp. 222, 223*).—A series of observations on the number of eggs laid in a 24-hr. period by a single female *C. curticei* are briefly referred to. The results show that there was a considerable difference between the number of eggs produced per female in the case of 1 of 3 animals which harbored only 286 female *C. curticei* and the number of eggs produced per female in 2 other animals which harbored, respectively, 4,137 and 3,832 female *C.* curticei. It is pointed out that this result is in line with the findings of other authors that the egg production per female decreases as the number of parasites increases.

The occurrence of Eperythrozoon ovis in Algeria [trans. title], A. DONATIEN and F. LESTOQUARD (*Bul. Soc. Path. Exot., 28 (1935), pp. 423–426; abs. in Vet. Bul., 6 (1936), No. 1, pp. 27, 28*).—In investigations of the characters of a strain of *E. ovis* discovered in a sheep in Algeria, sheep and goats were inoculated. This was followed in the sheep by a brief invasion of the blood and in the goats by a heavy blood invasion which persisted in some animals for several months but without any rise in temperature. The persistence of the parasites was revealed by splenectomy or by the relapses which occurred with superimposed infections, such as anaplasmosis. The organisms occurred in the red blood corpuscles or free in the plasma, and they appeared as dots about 0.25μ to 0.33μ in diameter, staining a pale pink with Giemsa.

The occurrence of Eperythrozoon ovis in France [trans. title], H. LAFENÊTRE (*Rev. Vét. [Toulouse], 88 (1936), Apr., pp. 200, 201*).—The hematozoal parasite of sheep *E. ovis*, closely related to *Anaplasma*, which was described and first reported by Neitz et al. (E. S. R., 73, p. 239) in 1934 from the Union of South Africa and discovered by Donatien and Lestoquard in Algerian sheep as above noted, is recorded for the first time in sheep in the south of France. The pathogenicity of the form occurring in France remains to be determined.

Tapeworm studies.—III, Sheep parasitized with one Moniezia expansa each, N. R. STOLL (*Jour. Parasitol., 22 (1936), No. 2, pp. 161–179, figs. 2*).—In this further contribution (E. S. R., 74, p. 545) two sheep, each harboring one *M. expansa*, were studied primarily with reference to the development and maintenance of the cestode infections. "Parasitism resulted from exposure to infested ground for 7⅛ hr. in November and 8 hr. in January, respectively. In the first case a prepatent period of 37 days was followed by a patent period of 54 days, although proglottids had ceased appearing 2 days earlier. Six days after the end of the patent period a single specimen of *M. expansa*, intact with scolex but not showing mature segments, was recovered at the autopsy of the host. A definite cycle of proglottid production was observed. It was high at the beginning of patency, then dropped sharply, and gradually rose again to about the original level before finally tapering off. The basis is given for the estimate of a total production during the patent period of about 4,000 proglottids

and between 40 and 80 million eggs. Mature segments totaling about 6 m were discharged. In the second case, not followed in such detail as the first, there was indicated a similar prepatent period, followed by a patent period of 7 weeks, an interpatent period of a week, and a period of renewed patency until slaughter of the host 4 weeks later, when one mature *M. expansa* was found."

A report on experimental infections of Ovis aries with the infective larvae of Ostertagia circumcincta, W. L. THRELKELD and T. O. DOWNING (*Jour. Parasitol., 22 (1936), No. 2, pp. 187–201, figs. 6*).—Experiments conducted at the Virginia Experiment Station with a view to determining the pathogenicity of the infective larvae of *O. circumcincta* on the host, with particular reference to the blood, are reported.

Light infections with *O. circumcincta* larvae (4,395–27,700) given over periods of from 2 weeks to 2 mo. 9 days to 3 lambs 4, 6, and 1 mo. old, respectively, apparently caused no injury to the host. Moderate numbers of larvae (46,685) given over a period of 4 mo. to a lamb 5 mo. old, caused no pathologic symptoms other than a loss in weight. Moderate numbers of larvae (55,000) given over a short period of time (1 week) to a lamb 7 mo. old produced a slight eosinophilia of a short duration. Large numbers of larvae (225,000) given to a lamb 1 mo. old, over a period of 1 week, affected the growth of the host animal. There was a decrease in the percentage of hemoglobin. The differential blood count indicated a decrease in the percentage of lymphocytes, a pronounced eosinophilia, and the appearance of undifferentiated cells designated as hemocytoblasts; the latter probably are called forth as red-cell precursors to counteract the anemia. Very great numbers of larvae (1,145,000) given to a lamb 8 weeks old over a period of 2 mo. 18 days caused a loss of weight and produced pathologic changes with erythrocytosis, followed by a decrease in the red cells, as well as a drop in the hemoglobin percentage and the number of lymphocytes. Hemocytoblasts appeared at this time. Moderate doses of larvae (55,000) and heavy doses of larvae (225,000) given over a period of 1 week to 2 lambs 7 and 1 mo. old, respectively, yielded a comparatively heavy egg output over short duration, 28 days to 1 mo. 28 days, which rapidly reached a maximum and rapidly decreased to permanent negative counts. This was a marked contrast to the histories of egg count readings obtained from 3 lambs which received doses of infective larvae over extended periods.

An experimental study of rinderpest virus in goats in a series of 150 direct passages, P. T. SAUNDERS and RAO SAHIB K. KYLASAM AYYAR (*Indian Jour. Vet. Sci. and Anim. Husb., 6 (1936), No. 1, pp. 1–86, pl. 1, figs. 82*).—In experimental work the mortality rate from rinderpest in control animals gave evidence of attenuation of the virus for bovines after the eightieth passage through goats. There was a constancy of reaction in the experimental goats in Madras with no evidence of attenuation for these animals. All of the experimental goats readily took the infection, and there is no indication that the virus cannot be maintained indefinitely through goats.

Trembling in pigs, E. H. HUGHES and R. HINMAN (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 96, 97*).—A brief report is made of two litters of pigs farrowed in the California Experiment Station herd in the spring of 1936, individuals in which exhibited a marked trembling. The condition, the cause of which has not been determined, is considered to be the same as that reported from Pennsylvania by S. M. Nissley in 1932.[8]

Infection of the Rhesus monkey (Macaca mulatta) and the guinea-pig with the virus of equine encephalomyelitis, E. W. HURST (*Jour. Path. and Bact., 42 (1936), No. 1, pp. 271–302, figs. 2*).—In the author's investigations, con-

[8] Jour. Amer. Vet. Med. Assoc., 81 (1932), No. 4, p. 551.

ducted with both the western and eastern strains of equine encephalomyelitis virus, but more often the latter, it was found that the course of the infection in guinea pigs or *Rhesus* monkeys may be divided into visceral and nervous phases. "In the guinea pig the two phases tend to overlap, in the monkey to be separated by an interval of several days. The nervous phase succeeds the visceral much less constantly in the monkey than in the guinea pig.

"During the visceral phase virus circulates in the blood in greater amount than can be accounted for readily by its titer in the viscera, while at a site of innoculation in muscle little or no multiplication takes place and in the dermis only moderate local increase. It seems, therefore, that the virus must multiply chiefily either in the blood or in some tissue intimately connected with the blood stream and forming only a small part by weight of the various viscera.

"In the monkey, nervous infection occurs at a time when the very prompt antibody response to the visceral infection is as complete as it ever will be; monkeys recovered from the visceral infection without obvious nervous involvement are not usually immune to intracerebral inoculation of fresh virus. On the other hand, guinea pigs recovered without having shown nervous symptoms are immune to subsequent intracerebral inoculation.

"Unlike many neurotropic viruses, the virus of equine encephalomyelitis inoculated intramuscularly or intradermally does not reach the central nervous system by way of the local peripheral nerves. In many cases the findings suggest that the nervous system is infected by virus which has during the period of blood circulation passed out on to the nasal mucosa, and thence by the perineural lymphatics of the olfactory nerve to the subdural space. The evidence presented does not finally exclude on the part of the virus a slow 'growth through' the hematoencephalic barrier as an alternative method of infection of the central nervous system, but in the monkey virus does not pass directly from the blood into the cerebrospinal fluid.

"Argument is advanced to show the probable close resemblance of the virus of equine encephalomyelitis to certain other viruses capable of exciting nervous disease, viz, those of vesicular stomatitis, yellow fever, and louping ill. As a group these viruses probably possess 'pantropic' affinities, but as they differ materially in their cellular affinities and mode of action from such pantropic viruses as pseudorabies, B virus, and herpes, they must be relegated to a separate group."

Further studies on the efficacy of fowl-pox vaccines, A. KOMAROV and I. J. KLIGLER (*Jour. Compar. Path. and Ther., 49 (1936), No. 1, pp. 90–95*).—Laboratory and field experiments here reported are considered to warrant the conclusion that (1) "fowl pox vaccine applied by the stick method on the wing to flocks 2- to 3-mo. old, of early hatch, results in few secondary lesions and confers a durable immunity", and (2) "it is not advisable to use this vaccine in late-hatched birds because these birds suffer from severe postvaccination reactions." It is suggested tentatively that late hatches be first vaccinated with pigeon pox vaccine and 2 mo. later with fowl pox.

Studies of pullorum disease.—II, The incidence of Salmonella pullorum in eggs from infected hens, W. L. MALLMANN and J. M. MOORE (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 35–52, fig. 1*).—In continuation of studies of pullorum disease at the Michigan Experiment Station (E. S. R., 71, p. 103) infertile eggs from reacting hens contained less *S. pullorum* infection than the fertile eggs from the same hens. "A study of eggs from reacting hens reveals that both dead germs and chicks dead in the shell show a much higher incidence of *S. pullorum* than the live chicks from the same hens.

The average incidence of *S. pullorum* in all the eggs from reactor stock is nearer that of the organism in the fertile eggs, rather than the average obtained by checking the presence of *S. pullorum* in both the fertile and infertile eggs. The percentage of infection shown by chicks hatched from reactor stock is remarkably low. The extent of the disease in the chick is probably due not to the large number of infected chicks hatched but to the spread from a few infected chicks during hatching and brooding. Apparently pullorum disease is very contagious. The need of segregation of clean stock, the immediate elimination of infected chicks, and the use of clean incubators and brooders is clearly demonstrated by this study."

Arthritis in a chick caused by Salmonella pullorum, F. R. BEAUDETTE (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 89–91*).—This brief review of the literature, contributed from the New Jersey Experiment Stations, indicates that *S. pullorum* may be isolated, as a localized infection, from the ovary, testes, spleen, gall bladder, thoracic abscess, myocardium, pericardial sac, skin, middle ear, and the joint cavity.

Variation of Salmonella pullorum, H. VAN ROEKEL and L. F. RETTGER (*Jour. Infect. Diseases, 58 (1936), No. 2, pp. 172–184, figs. 7*).—This contribution reports upon the behavior of 13 variants detected among 163 freshly isolated strains of *S. pullorum* during the course of a study of the variation of this organism (E. S. R., 73, p. 854). "The behavior of these variants in sodium chloride solution of different concentrations and in the presence of positive and negative serums differed greatly. Other properties, such as colonial and cellular morphology, Gram-staining, and biochemical reactions revealed little or no variation, on the whole. *S. pullorum* strains readily underwent variation when subjected to frequent transfer and storage in beef infusion broth. When variants were cultivated on both meat extract agar and liver infusion agar the colonial and cellular features often appeared markedly different. Some strains that appeared normal on meat extract agar exhibited pleomorphic tendencies when placed on liver infusion agar Most variants exhibited a lesser degree of virulence than their parent strains, and in some instances appeared avirulent. The agglutinogenic power and the absorptive capacity of the variants tested were not equal to those of the normal type."

The resistance of Salmonella pullorum to the action of various disinfectants, E. C. MCCULLOCH and S. COSTIGAN (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 53–58*).—The results of tests made of the viability of *S. pullorum* in chicken manure suspensions and the disinfection of *S. pullorum* with phenol, liquor cresolis, formaldehyde, sodium hypochlorite, and lye are reported in table form.

The results show that the disinfectants may be divided into two classes. The phenol, the liquor cresolis, and the formaldehyde are markedly affected by the temperature, while the sodium hypochlorite and the lye are but slightly influenced. On the basis of the concentration required to kill in 10 min. but not in 5, in the absence of added organic matter and at 2° C., phenol killed *S. pullorum* in a dilution of 1:50, liquor cresolis in 1:65, formaldehyde in 1:25, sodium hyperchlorite 70 p. p. m. of available chlorine, and lye in 1:1,175.

The addition of chicken manure only slightly influenced the results; in the presence of light and heavy chicken manure suspensions at 2°, the mean phenol coefficients are as follows: Liquor cresolis 1.35, formaldehyde 0.45, available chlorine 333, and lye 15.75.

"At 20°, in the absence of added organic matter, phenol killed *S. pullorum* in 1:80, liquor cresolis in 1:125, formaldehyde in 1:50, sodium hypochlorite

in a concentration of 50 p. p. m. of available chlorine, and lye in 1:1,250. In the presence of the heavy suspension of chicken manure, lye killed in 1:750. At this temperature the mean phenol coefficients are liquor cresolis 1.77, formaldehyde 0.71, available chlorine 250, and lye 12.5.

"At 40° a 1:175 phenol dilution and a 1:400 liquor cresolis dilution killed *S. pullorum* in the absence of chicken manure, while a 1:350 dilution killed when it was present; formaldehyde (1:200) killed in the absence of chicken manure, and a 1:150 dilution killed when it was present; sodium hypochlorite (40 p. p. m.) killed; and lye killed in dilutions of 1:1,250 to 1:1,500. The mean phenol coefficients at 40° are liquor cresolis 2.1, formaldehyde 1, available chlorine 143, and lye 7.6."

The cellular elements and hemoglobin in the blood of chickens with spontaneous tuberculosis, C. OLSON, JR., and W. H. FELDMAN (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 26–34*).—A report is made of a study of the blood of eight female Rhode Island Red fowl 2 to 3 yr. old which had reacted positively to intradermal injections of avian tuberculin. One failed to give macroscopic or microscopic evidence of the disease at necropsy and also presented essentially normal hematologic findings. The seven tuberculous birds revealed leucocytosis, especially in regard to the heterophile granulocytes and monocytes. The degree of leucocytosis was about in direct ratio with the extent of the tuberculosis. In none of the tuberculous fowls studied was there any indication of anemia. Attempts to obtain cultures of the avian type of the organism in the circulatory blood failed in all but one instance.

An outbreak of aegyptianellosis in Pekin ducks, J. D. W. A. COLES (*Jour. So. African Vet. Med. Assoc., 5 (1934), No. 2, p. 131*).—The occurrence of the parasite *Aegyptianella pullorum* in a diseased 2-month-old Peking duck in a flock at Pretoria North, Union of South Africa, in which 10 were affected, is reported. The presence of the disease in chickens on the same farm is said to have been detected by the author the preceding year.

Paratyphoid infection in turkeys, C. D. LEE, G. HOLM, and C. MURRAY (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 65–76*).—A paratyphoid organism was isolated from turkey poults of various ages under 5 weeks from farms in widely distributed areas in Iowa, where large losses were experienced by the owners in 1934. The incidence of occurrence on the same farms was low the second year.

"A general systematic study of the organism, including the application of the simple agglutination test as well as the agglutinin absorption test, identified the organism as *Salmonella aertrycke* type. The organism is highly virulent for baby chicks, young poults, guinea pigs, and rabbits when administered orally, intraperitoneally, or intravenously. Newly hatched poults may spread the infection to others. The cycle of infection seems to be very similar to *S. pullorum* infection in chickens. The symptoms are weakness, unthriftiness, loss of appetite, ruffling of feathers, dragging of wings, sleepiness, diarrhea, sudden onset, and high mortality. The lesions of the disease in turkey poults may be said to be duodenitis, hyperemia of the liver and kidneys, hyperplasia of bone marrow of the long bones, a distention and filling of the ceca with a cheesy, coagulated plug of fecal material, undigested feed material, and epithelial debris. The blood picture presents a leucocytosis with a large degree of monocytosis."

Species of Capillaria parasitic in the upper digestive tract of birds, E. B. CRAM (*U. S. Dept. Agr., Tech. Bul. 516 (1936), pp. 28, figs. 12*).—The status of the present knowledge of 11 species of nematodes of the genus *Capillaria* occurring in parts of the digestive tract of birds anterior to the intestines is considered.

The species *C. charadrii* (Rudolphi 1819) Travassos 1915 is said to be nomen nudum and therefore unrecognizable. A morphological description is given of each of the other 10 species, namely, *C. annulata* (Molin 1858) Cram 1926, *C. contorta* (Creplin 1839) Travassos 1915, *C. corvicula* (Wassilkowa 1930) Baylis 1931, *C. cylindrica* (Eberth 1863) Travassos 1915, *C. dispar* (Dujardin 1845) Travassos 1915, *C. laricola* (Wassilkowa 1930) Baylis 1931, *C. lophortygis* Baylis 1934, *C. obtusiuscula* (Rudolphi 1819) Travassos 1915, *C. perforans* Kotlán and Orosz 1931, and *C. triloba* (Linstow 1875) Travassos 1915.

The author concludes that external characters rather than an internal character, such as the spicule, are of primary importance in the recognition of *C. contorta*, and on that basis has allocated as that species a capillarid found by her in the esophagus, including the crop, of a considerable number of gallinaceous and a few anseriform birds. It is pointed out that the present descriptions of two recently created species, *C. lophortygis* and *C. perforans*, are inadequate for satisfactory differentiation of them from *C. contorta*.

"Three species, namely, *C. annulata*, *C. contorta*, and *C. dispar*, are known to produce severe pathological effects, which are described. Of these species, the first two have appeared to be of increasing economic importance in poultry and game birds in the United States during the past decade. Attempts to produce artificial infestations with *C. annulata* were unsuccessful, but experimental proof of the complete life cycle of *C. contorta* was obtained. . . .

"Six turkeys and two bobwhite quail were experimentally infected in such well-controlled experiments that no doubt existed as to the origin of the parasites; the cultures used for these experiments included strains of *C. contorta* from the bobwhite quail, mountain quail, ring-necked pheasant, and turkey. In addition, specimens of *C. contorta* from a domestic duck, a young Peking, were thought to have developed as a result of an artificial feeding with a culture of the pheasant strain, although the presence of a few specimens of the parasite in a control duck raised the question as to the origin of the infestations. Later attempts to infect ducks were unsuccessful, possibly due to the age or race of the birds used; negative results were obtained also in several cases with turkeys. Only negative results followed repeated attempts to infect chickens, guinea fowls, and pigeons, and a single attempt to infect a crow."

A list is given of 52 references to the literature cited.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Idaho Station], H. BEERSFORD (*Idaho Sta. Bul. 220 (1936), pp. 12–16, 28, 29, fig. 1*).—The progress results are briefly presented of investigations on drainage effect of wells; new types of farm machinery, including the small-size, high-speed, all-crop combine, and plow attachments for pea weevil control; production of alcohol from potatoes; power and labor utilization in Idaho creameries; dairy barn ventilation; rural electrification, including supplementary electric heat in poultry laying houses, and the use of electric fences; and the distribution and costs of steam, electrical power, and labor in Idaho creameries.

[Agricultural engineering investigations by the Michigan Station], H. H. MUSSELMAN (*Michigan Sta. Rpt. 1935, p. 158*).—A very brief progress report is presented of investigations on bindweed control equipment, porous canvas hose irrigation, and low-pressure tires on tractors.

[Agricultural engineering investigations by the Montana Station] (*Montana Sta. Rpt. 1934, pp. 45–48*).—The progress results are briefly presented of investigations on the storage and use of flood waters for irrigation, water wheels and pumps for irrigation, and irrigation methods.

[Terracing and water and sewage investigations by the New Jersey Stations] (*New Jersey Stas. Rpt. 1935, pp. 12–14, 89–94*).—The progress results of investigations are briefly presented on terracing, activated sludge, sewage chlorination, chemical precipitation of sewage, sewage sludge dewatering, use of activated carbon in sewage treatment, pathogenic organisms in sewage, and high and low temperature digestion of sewage.

[Agricultural engineering investigations by the South Dakota Station], R. L. PATTY (*South Dakota Sta. Rpt. 1935, pp. 8–11, 45*).—The progress results are briefly presented of investigations on field machinery hitches for tractors and large horse teams, rammed earth for farm building walls, corn harvesting machinery, protective coverings and length of service of steel fence posts, and rammed earth walls in poultry house construction.

American Farm Bureau Federation, Institute of Irrigation Agriculture, Fourth Water Users Conference, Los Angeles, Feb. 25–27, 1935 ([*Chicago: Amer. Farm Bur. Fed., 1935*], *pp.* [*3*]+*99, pl. 1*).—This institute included, among others, special papers on Underground Water, by H. Conkling; The Use of Power on Irrigation Projects, by C. L. Childers; Underground Water, by J. J. Deuel; Measures Taken to Alleviate the Effects of the Drought of 1934, by W. W. McLaughlin; and The Movement and Control of Underground Water, by W. Peterson.

American Society of Civil Engineers, Report on Progress Conference on Water Conservation, Los Angeles, Mar. 13, 14, 1935 ([*Los Angeles: Amer. Soc. Civ. Engin.*], *1935, pp.* [*3*]+*102*).—This report, presented by the committee on conservation of water of the irrigation division of the American Society of Civil Engineers, contains special papers and reports on Evaporation Studies in Southern California, by H. F. Blaney and A. A. Young; Use of a Limited Water Supply for Irrigating Citrus Orchards, by C. A. Taylor; Law of Underground Waters, by H. Conkling; Economic Limits of Conservation of Flood Water by Spreading, by K. Q. Volk; Runoff From Small Experimental Plots, by F. B. Laverty; Measurement of Debris Transported from Burned Areas, by C. W. Sopp; Check Dams, by P. Bauman; Erosion Control, by H. E. Reddick; Forest Influence Studies at the San Dimas Experimental Forest, by E. I. Kotok; Safeguards on Denuded Watersheds, by W. V. Mendenhall; Runoff and Erosion Experiments in Mountain Areas, by C. J. Kraebel; and Erosion and Runoff Experiments from Cultivated Areas, by L. A. Jones.

American Farm Bureau Federation, Institute of Irrigation Agriculture, Fifth Annual Conference, Salt Lake City, Mar. 11–13, 1936 ([*Chicago: Amer. Farm Bur. Fed., 1936*], *pp.* [*4*]+*82*+*16*).—This institute included, among others, special papers on Basic Information Relating to Hydrology of the Region West of the 100th Meridian, Including a Study of Methods and Results of Snow Surveys, by G. D. Clyde; How the Great Plains Area is Meeting the Problems of Irrigation Pumping, by G. S. Knapp; A Committee Report of Recent Research and Investigational Work on Irrigation and Drainage in the Western States, by W. W. McLaughlin, C. S. Scofield, and O. W. Israelson; Practical Irrigation Problems on Which Farmers Need Assistance, by W. Peterson; A Study of the Preferential Rights in the Use of Water and Their Relation to Agriculture and of Authority for Enforcement, by G. E. P. Smith; A Critical Study of the Recommendations of the National Resources Board, by R. B. West; and The Place of Reclamation in the National Agricultural Program, by M. L. Wilson.

Experimental verification of pump well theories, T. R. COLLIER and W. GARDNER (*Utah Acad. Sci., Arts, and Letters, Proc., 12 (1934–35), pp. 177–179, figs. 2*).—In a brief contribution from the Utah Experiment Station an attempt

is made to verify experimentally the conclusions of Eliason and Gardner reported in a previous article (E. S. R., 69, p. 437).

Partial list of Government publications of interest to architects, builders, and retail lumbermen (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab., 1936, pp. 16*).—This mimeographed list relates mainly to fungus defects in forest products; the growth, structure, and identification of wood: manufacture and grading of lumber; mechanical properties and structural uses of wood and wood products; the seasoning of wood; wood finishing subjects; and wood preservation.

The relation of colloids in soil to its favorable use in pisé or rammed earth walls, R. L. PATTY (*South Dakota Sta. Bul. 298 (1936), pp. 23, figs. 13*).—This bulletin summarizes results of studies in progress at the station for several years on rammed earth as a structural material and refers particularly to recent studies on the soil colloid relationships.

It has been found that a soil low in colloids is favorable for pisé walls and resists weathering action well. A soil that tests high in colloids is unfavorable for the purpose. A test for colloids not only identifies the soil as being favorable or unfavorable, but indicates just how favorable it will be.

The hydrometer method of soil analysis was found to lend itself well to work with earth walls. With this method the colloidal content of a soil can be obtained in 40 min. after the sample has been dried to constant weight. Heavy clay soils high in colloids were found to be unfavorable for rammed earth walls, while light sandy soils low in colloids were very favorable. The dividing line was found to be a colloidal content of 40 percent. Soils containing more than 40 percent colloids are not fit to use as they are, and in few cases can such soils be made satisfactory for the purpose by adding a reasonable amount of sand or by special protective coverings.

Silt seems to be more favorable in a soil than clay. Although no uniform ratio is shown between the silt content and the quality of the wall, it is apparent that silt is generally favorable. It is also true that a silty soil makes an excellent wall when sand is artificially added.

Sand is distinctly favorable in a soil for pisé work. Sandy soil resists weathering, rams much more quickly, holds protective coverings well, and probably will hold oil paints. It was found that no soil containing less than 80 percent sand is too sandy for the purpose.

Additional findings since a previous account (E. S. R., 70, p. 260) are given. Foundations for pisé walls should extend from 12 to 15 in. above the ground except in cases in which cement stuccoes are used for coverings, in which case 9 in. may be sufficient. Rammed earth increases in strength with age in the same way as does concrete. The average increase in strength was 45 percent over a period of 2 yr.

Age-strength relationship for rammed earth, R. L. PATTY (*Engin. News-Rec., 117 (1936), No. 2, p. 44, figs. 2*).—In tests conducted at the South Dakota Experiment Station on the relation of age to the strength of rammed earth, three base soils were used and 12 test blocks were made from each soil on the same day and from the same pile of earth. The first was a very heavy clay soil, the second a medium sandy soil, and the third a very sandy soil. At the end of 6 mo. four blocks of each soil were tested to failure, at the end of 1 yr. four other blocks of each of the soils were broken, and at the end of 2 yr. the final four blocks of each soil were broken. Upon averaging the strength of each group of test blocks an increase in strength was shown in the case of each soil. At the end of 1 yr. the average increase in strength over the 6-mo. test blocks was 33.7 percent, and at the end of 2 yr. the average increase in strength over the 6-mo. blocks was 45 percent.

The heavy clay soil had the greatest early strength, and it was still first in strength at the end of 2 yr., but the results showed that the sandier soils gained more strength with age. Clay soil is not a favorable soil for pisé walls in spite of its superior strength, because it has a tendency to slake in the wall and does not resist the action of weathering as well as the soils containing less clay. Of the three soils used in this strength test, soil containing 74.82 percent of sand made the best wall.

Hardwoods of the South (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab., 1935, pp. 16, figs. 14*).—Southern hardwoods are discussed briefly with reference to texture, planing, shaping, turning, bending, warping, cross grain, seasoning, splitting, nail holding, screw holding, gluing, and odor and taste.

Operating small sawmills, methods, bibliography, and sources of equipment, C. J. TELFORD (*U. S. Dept. Agr., Forest Serv., Forest Prod. Lab., 1936, pp.* [2]+*40*).—This is a technical treatise on financing and operation of logging and milling outfits, with information on timber appraisal and marketing. A list of manufacturers of dry kilns, sawmills, and accessories in the United States is included.

The measurement of the flow of air through timber seasoning stacks, W. L. GREENHILL (*Jour. Council Sci. and Indus. Res.* [*Austral.*], *9 (1936), No. 2, pp. 128–134, figs. 4*).—A method of measuring the air velocity through timber stacks by means of a vane anemometer is described. Correction factors, which, for any particular type of anemometer, were found to depend on the thickness of the timber and of the separating strips, on the velocity of the air, and on the position in which the anemometer is held, have been determined for a number of cases.

Tests on the strength of beams notched in various ways, I. LANGLANDS (*Jour. Council Sci. and Indus. Res.* [*Austral.*], *9 (1936), No. 2, pp. 88–96, figs. 2*).—Three series of tests on long and short beams of Australian timber are reported, one on 4- by 2-in. specimens designed to fail in shear even when not notched and the others on 4- by 2-in. and 3- by 2-in. specimens of such length that they would normally fail in bending.

It was found that notching the ends of beams and joists seriously affects their strength. It is therefore advisable not to notch the ends of a joint or beam whenever it can be avoided. The reduction in strength can be obtained with fair accuracy from the U. S. D. A. Forest Service formula. If it is necessary to notch the beam its strength can be about doubled (or under certain conditions even brought up to the strength of an unnotched beam) by cutting away the bottom portion of the beam at the notch by means of a slanting saw cut with a slope of about 1 in 3 to the axis of the beam.

Load performance tests of precast joist-precast slab floor construction, R. E. COPELAND (*Jour. Amer. Concrete Inst., 7 (1935), No. 2, pp. 195–211, figs. 9*).—The tests reported were conducted on a type of light weight concrete floor constructed of precast reinforced concrete slab sections laid on and united to precast reinforced concrete joists. Seventeen large panels were tested, all of 14-ft. clear span except one of 20-ft. span. All panels were tested with uniformly distributed load except one panel where the load was applied at the midspan and quarter points.

The loads placed on the panels ranged from 40 lb. per square foot for the panels having the weakest bond joints to 445 lb. per square foot. Yield point stress in the tension steel was produced by a load of 200 lb. per square foot in the case of the panel with joists functioning as independent members and by loads of from 275 to 288 lb. per square foot in the case of 14-ft. span panels functioning as a T-section.

The deflections due to the weight of the slabs averaged about 0.12 in. for the 14-ft. panels and 0.2 in. for the 20-ft. panel.

The plain bond joint, type 1, whose shear resistance depends wholly on the adhesion of the mortar to the precast members, failed with panel loads of 40 lb. per square foot with smooth textured mortar contact surfaces, and with panel loads of from 40 to 160 lb. per square foot with rough textured mortar contact surfaces. Joint types 2 and 3, providing for a mechanical bond by interlocking the slab units with the joist, performed very satisfactorily and were relatively stronger in panel load capacity than the tension reinforcement. In joint types 4 and 5, in which mechanical bond was obtained by means of the irregular or serrated mortar contact surfaces forming a series of small mortar keys, joint type 4 fractured at a load of 220 lb. per square foot and joint type 5 at a load of 218 lb.

The results in general are taken to indicate that it is possible and practicable to construct precast joist-precast slab floors in such a manner that the joist and slab function together as a T-section.

Considering the range of mortar strengths studied, strength of mortar was not an important factor, but it is believed that the mortar should be at least as strong as the 1:1:6 cement-lime mortar used. Panels constructed of Haydite concrete performed similarly to comparison panels made of sand and gravel concrete. Within the range of conditions studied, variations of span length and type of loading produced no appreciable effect on load performance.

One hour fire test of fire-retardant wood door, A. S. WILLIAMS (*Amer. Wood-Preservers' Assoc. Proc., 31 (1935), pp. 225–229, figs. 3*).—In this experiment the test assembly consisted of a flush-type wood door 1¾ in. thick, 36 in. wide, and 79¾ in. high. The door was composed of a fire-retardant wood core constructed of chestnut strips approximately 1⅜ in. wide, assembled so as to form two 5-in. stiles, running the full length of the door and joined by four 10-in. cross rails, thus providing for three panels 13¼ by 26 in., which in turn were divided at the middle by means of a 5-in. short stile joined to the cross rails. The rails were joined to the stiles by tongue-and-groove joints supported by dowels. The core thus assembled was covered with a ⅛-in. cross band of fire-retardant poplar, and the door was finished with ⅛-in. untreated birch veneer. The door was hung with ⅛-in. clearances at top and sides and ⅛ in. at bottom. The test structure consisted of a gas-fired furnace having an opening 62 by 93 in., which formed one wall of a vestibule with the test assembly in place.

The test was conducted in accordance with the procedure outlined in the Standard Fire-Test Specification C 19–33 of the American Society for Testing Materials. The temperature rise on the unexposed face of the door was 176° F. above the initial vestibule temperature. The door showed practically no deformation at the end of the test and remained secure in the frame. The unexposed face of the door showed no discoloration, and at no time did flame appear on the unexposed face. No smoke was evolved by the test assembly, and only a small amount of smoke passed through the openings when the furnace damper was closed near the beginning of the test.

Corrosion: Causes and prevention, F. N. SPELLER (*New York and London: McGraw-Hill Book Co., 1935, 2. ed., pp. XIII+694, figs. 141*).—This is the second edition of this book. It deals with the nature and mechanism of corrosion: principles and methods of corrosion testing; relative corrosion of ferrous metals; prevention of corrosion in the atmosphere, under water, in closed water systems by removal of dissolved gases, in high-pressure steam plants—boiler water treatment, in steam and hot water heating systems, in chemical

industries, and underground; and stray-current electrolysis. The book also contains an appendix on the calculation of corrosion rates in terms of penetration in inches per year, the marble test of Von Heyer, determination of sodium sulfite, and retarding corrosion in refrigerating plants and a selected bibliography on the corrosion of ferrous metals.

Studies on the use of the terracing plow for soil conservation, H. J. HARPER (*Jour. Amer. Soc. Agron., 28 (1936), No. 4, pp. 301–309, figs. 3*).—Studies at the Oklahoma Experiment Station on the terracing plow are reported, the purpose of which was to determine its limitations in a soil conservation program.

It was found that the effective height of terrace ridges could be increased by plowing twice in the same furrow for three or four rounds. When a riding plow is used a deep narrow furrow slice should be moved toward the terrace ridge. A moldboard designed with the outer end flattened and bent slightly to the rear at a point about 22 in. from the edge of the landside will operate easier along crooked furrows in soil where sods are frequently encountered and in soil which tends to stick near the end of a straight moldboard.

The draft of a terracing plow is very similar to that of a general-purpose plow when operating under similar conditions. A plow operating in subsurface soil required about twice as much power as the same plow operating in surface soil. When terrace ridges are being constructed with a terracing plow the land should be planted to small grain or some other crop which will cover the surface of the ground and reduce the erosion which may occur from breaks in the low ridges, unless the ridges can be plowed two or three times during the fall or winter in order to increase the effective height. When row crops are grown the rows should be planted on a contour and parallel with the terrace ridge. The terracing plow was more useful that a backfilling plow or an ordinary plow in gully control work where soil is removed from the upper edge of a bank in order to establish a more vigorous growth of vegetation in the bottom of the ditch.

The combine harvester, E. G. GREST (*Sci. Agr., 15 (1934), No. 4, pp. 244–246*).—In a brief contribution from the Canadian Department of Agriculture, an analysis of data relating to combine harvester cost is presented for 63 machines. It was found that in most cases 700 acres or more for a 15–16 ft. combine and 525 acres or more for a 10–12 ft. combine must be harvested per year to obtain a reasonable cost per acre of crop harvested.

Small-grain nursery equipment, H. M. BROWN and J. W. THAYER, JR. (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 395–403, figs. 8*).—The five machines developed at the Michigan Experiment Station and in use on the plant breeding plats include a planter, a garden tractor grain nursery cutter, a bagger, a tier, and a nursery thresher.

Gardening by electricity, "TRICIAN" (*Rural Electrif. and Electro-Farming, 11 (1936), No. 133, pp. 407–409, figs. 3*).—Applications of electricity to small-scale gardening operations in England are briefly described.

Electricity in poultry farming, C. A. CAMERON BROWN (*Oxford: Univ. Oxford Inst. Res. Agr. Engin., 1935, pp. 73, pls. 12*).—This is a conservative analysis of data relating to the uses of electricity on poultry farms in England, as gathered from a survey of the experiences of a large number of farmers in different parts of the country and as obtained from the work of various research institutions.

It is concluded that the use of electrical methods in poultry farming has become technically successful. The fear of current failure appears to be the biggest single objection to the general adoption of electrical methods where the cost is favorable.

With reference to the cost of running, all-electric incubators using current at 1.25d. per unit compare favorably with oil-heated machines, bearing in mind the extra labor and the wastage with oil. At 1d. per unit the all-electric incubator is as cheap as oil under average conditions on all grounds, and at prices less than 1d. the all-electric machine is cheaper. While the economic results are best in the bigger cabinet machines, the use of electricty in the smaller and in the table machines is particularly appreciated in districts where poultry farming is incidental to mixed farming.

For rearing, electricity cannot compete with oil- or coal-fired, central-heated, hot-water plants on large farms, but it is better than oil for battery brooding and the cost is reasonable at unit prices up to 1.25d. or so. For hover heating it is competitive with oil at the same price per unit only if great care is taken in operating the controls or if automatic control is fitted, and a rate of from 0.5 to 0.75d. per unit is necessary to allow hover heating to be developed to any extent.

Lighting of laying houses is successful, but the costs determined in tests should be related to prevailing market prices. The application showed a substantial profit per bird in the conditions experienced during the 1930–31 season.

With reference to the quality of output the electrical methods are criticized in some quarters on the grounds of producing poorer and less virile birds. This does not appear to be true in connection with rearing, compared at least with other methods of heating, but in hatching there is definitely a tendency to hatch out the less virile chicks which would otherwise have failed to survive. The remedy is drastic inspection and culling, and this illustrates that the use of these modern methods is only for the experienced poultryman who knows both how to appreciate the labor-saving devices and to recognize their limitations. Doubts may exist as to the reliability of the supply, but there is no doubt that operation with electrical appliances is more convenient and pleasant than with any other type.

A "two-way" candling and grading bench for use in egg packing plants, E. R. MENEFEE (*Poultry Sci., 15 (1936), No. 2, pp. 125, 126, fig. 1*).—In a brief contribution from the Indiana Experiment Station, a description is given of a grading and candling device which is used in several Indiana packing plants where eggs are being graded under the U. S. Government standards.

Air conditioning by the sun, W. P. GREEN (*Mech. Engin. [New York], 58 (1936), No. 6, pp. 369–371*).—Studies conducted at the University of Florida on the possibility of using solar energy for air conditioning in Florida are briefly reported.

In order to secure definite information as to how much heat can be expected from a square foot of Florida sunlighted area, a parabolic-trough or cylinder-type heater was built and mounted upon the roof of the engineering shops at the university. The reflector has a length of 3 ft. and a width of 4 ft. and is enclosed in a sheet metal case insulated inside with a single thickness of celotex. The reflector material is a thin sheet of nickel-plated zinc. The top of the reflector case is covered with ordinary window glass. The collector is turned about an axis, parallel to the earth's axis of rotation, by a system of weights and is so timed by two alarm clock motors as to be facing the sun continually. At the focus of the reflector inside its case there is a 2-in. round iron pipe which has inside of it a 1.25-in. pipe. Water circulates by gravity between the two pipes and is heated by the sun's rays which the reflector concentrates upon the pipe. Provision is made for measuring the quantity of water circulating and the temperature rise.

Results obtained during runs in November, 1934 and 1935, showed as high as 128 B. t. u. per square foot per hour of sunshine collected was possible with

this simple type of construction. Radiation losses being less will tend to increase this value during the summer, although the increase in the humidity of the air during the summer cuts down the atmospheric transmission of solar energy. Operating temperatures as high as 220° F. were readily obtainable, the aforementioned test being run at 210°. When filled with water and with all outlets closed, the steam pressure rose to 50 lb. per square-inch-gage, indicating a temperature in the absorber of approximately 300°. The ratio of the area of sunshine collected (concentration ratio) to the area of the absorbing surface in this collector is approximately 6.5:1. Since it is desirable to reach the temperature of 250° in operation and above 300° as a maximum, the concentration ratio should be increased to about 11:1. This will also increase the operating efficiency of the unit, since the radiating surface of the absorber will be decreased and therefore both radiation and convection losses from this surface cut down.

The requirements for a solar energy refrigeration plant are briefly outlined, it being concluded that a reflector surface collecting 360 sq. ft. of sunshine per ton of refrigeration is indicated. To take care of losses this should be increased to 400 sq. ft.

Provision for storing the heat collected, or a part of it, so that the plant could remain in operation during cloudy periods and for at least 3 hr. after sunset will mean the storing of hot water or some other heated medium in sufficient quantities to furnish the reserve heat necessary for efficient operation. Insulated storage tanks will make this feasible. The storage of water at a maximum pressure of 80 lb. per square-inch-gage is recommended.

The use of an electric steam generator for the sterilization of dairy utensils on the farm, H. G. LINDQUIST (*Milk Plant Mo., 25 (1936), No. 1, pp. 30–32, fig. 1*).—This contribution from the Massachusetts Experiment Station describes the operation of a small electric steam generator and presents data on the efficiency of the unit for sterilizing various farm dairy utensils which had been contaminated with a specially prepared culture containing miscellaneous milk-grown organisms and coli aerogenes from cow manure. Utensils such as pails, strainers, and cans when exposed over the steam jet of this unit for from 4 to 7 min. were rendered practically sterile and dried out in a few minutes after removal from the sterilizer. Steam was available within 3.5 to 4 min. after turning on the current when operated at room temperature and in from 4 to 5 min. when operated at a temperature below 32° F. The unit required 0.85 kw.-hr. per hour for operation.

Effect of nature of filling material and dosing cycle on purification of creamery wastes, M. LEVINE, G. H. NELSON, and H. E. GORESLINE (*Iowa Engin. Expt. Sta. Bul. 124 (1935), pp. 56, figs. 3*).—The effects of various filling materials and dosing cycles upon the purification effected by, and the rate of discharge from, trickling filters were investigated in these studies, and the influence of the rate of discharge on the composition of the effluents was also observed. Sectional lath and cinder filters and solid cinder, quartzite, gravel, spiral ring packing, broken tile (burned clay), and corncob filters were studied. All filters were 2 ft. square and 6 ft. deep. Sectional filters consisted of six sections, each a foot high, separated vertically by 4-in. spaces. The waste was skim milk applied at the 24-hr. dosing rate of 550,000 gal. per acre. Actual application was made over a period of from 16 to 20 hr. per day. The concentration of the waste varied from about 200 to 1,600 p. p. m. oxygen demand.

Extremely high efficiencies were obtained with cinders, but they clogged quite frequently so that it was necessary to wash the filter after about 5 mo. of

operation. Moderate doses of $MgSO_4$, $CaCl_2$, and Na_2SO_4 did not affect the cinder filter efficiency.

The purification effected by corncobs was unexpectedly high, although nitrification did not develop. The corncob filter bed shrank 35 percent in depth. Efficiency decreased sharply at the end of the test, perhaps indicating an imminent failure in the purification function.

The 3-in. spiral packing was too large for outstanding results. Nitrification was quite satisfactory, however, and for smaller rings excellent results can be expected without danger of the clogging which eventually ensued in cinders, gravel, and broken tile.

Dosing cycles did not affect the efficiency of cinder filters, but on the quartzite the efficiency decreased as the length of cycle increased. Nitrate content of effluent was not affected. Probably some of the wastes were short circuited with the longer dosing cycles. With the longer cycles there were surges of comparatively unpurified sewage. Short cycles (2.5 to 5 min.) effected higher purifications, more constant run-offs, and more nearly uniform composition of effluents than did longer cycles (20 to 22 min.).

The more uniform the rate of run-off the more nearly the peak efficiency is reached for any given load.

Some observations on the European broad fish tapeworm Diphyllobothrium latum, J. E. THOMPSON (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 1, pp. 77–86, figs. 4*).—This is a report of observations conducted in Minnesota. It is pointed out that since ova of *D. latum* can pass through an Imhoff tank, the presence or absence of parasite ova in a sewerage system effluent should be used as an additional index in judging the efficiency of such plants.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Bul. 181 (1936), pp. 98–102, fig. 1*).—The table of index numbers of production, prices, and income, by J. I. Falconer (E. S. R., 75, p. 555), is brought down through April 1936, and an article on Livestock Auctions in Ohio, by G. F. Henning and P. S. Eckert (pp. 98–101), showing the location of such auctions, the numbers of livestock handled yearly, the area of yards and premises, and the number of pens used by the 57 auctions handling more than 3,000 head of livestock annually, is included.

Current Farm Economics,, Oklahoma, [June 1936] (*Oklahoma Sta., Cur. Farm Econ., 9 (1936), No. 3, pp. 65–80, figs. 2*).—Included are articles as follows: The Oklahoma Farm Price of Cattle as Compared with the Kansas City and Chicago Price of Stockers and Feeders, by W. J. Fessler; Wheat Situation, by T. R. Hedges; Quality of the Oklahoma Cotton Crop for the Crop Year 1935, and Some Effects of Returning Classification Cards to Patrons of Gins Cooperating with Grade and Staple Statistics Section, both by C. B. Barre; and Some Financial Aspects of Cooperative Ginning of Cotton, by A. W. Jacob.

Rural land economics, 1933–1935, compiled by O. CUMMINGS (*California Sta., 1936, pp. [118]*).—This mimeographed bibliography includes "outstanding references relating to rural land economics, especially to the present national land policy."

Factors determining type-of-farming areas in Nebraska, L. F. GAREY (*Nebraska Sta. Bul. 299 (1936), pp. 32, figs. 16*).—This bulletin supersedes Bulletin 244 (E. S. R., 63, p. 884). It describes the physical, biological, economic, and other factors determining types of production in the State, and

the shifts in crops, livestock, and income that have taken place in the State from 1910 to 1934. Thirteen type-of-farming areas are designated for the State and described.

Evolution of an agricultural policy for Montana (*Montana Sta. Rpt. 1934, pp. 10–27, figs. 7*).—The investigations of the station in regard to land settlement, use, and ownership; taxes; irrigation; and range use are briefly discussed.

The rural indebtedness situation in Puerto Rico [trans. title], S. L. DESCARTES (*Puerto Rico Col. Sta. Bul. 42 (1936), Span. ed., pp. 44, figs. 2*).—This study is based chiefly on data obtained regarding 1,731 holdings, including about 12 percent of the total rural indebtedness of the island. Analyses are made to show the distribution of the indebtedness among different types of agricultural enterprises, increase in indebtedness 1920–34, sources of funds, relation of indebtedness to value of property, term of loans, interest rates, etc.

The total value of the properties studied was approximately $13,200,000 and the total indebtedness $6,000,000, which represented 83 percent of the value of the 906 holdings having indebtedness. The amount of indebtedness in 1930 was 297 percent of that in 1920. There was a decline to 286 percent in 1934. The indebtedness on coffee properties amounted to 82 percent of the estimated actual value of such holdings and to 102 percent of the actual value of the holdings with indebtedness. The percentages for other properties were sugar 34 and 68, tobacco 60 and 98, small fruits 41 and 89, tree fruits 69 and 79, and miscellaneous 35 and 96, respectively. For loans other than those from the Federal Bank and the Rehabilitation Commission the rate of interest varied from 7.4 to 8.9 percent, and the length of the loans averaged 4.1 yr.

Farmer bankruptcies decline further in 1935, but are exceeded in number by debt compositions and extensions (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. 5*).—Tables show by States for 1934 and 1935 the total number of bankruptcies and number of bankruptcies among farmers; the total number of bankruptcies and the number by farmers, employees and professionals, merchants, manufacturers, and other classes by years 1928–35; and the compositions and extensions of farmer cases during the fiscal year ended June 30, 1935, under sections 12, 74, and 75 of the National Bankruptcy Act.

Part-time farming in New Castle County, Delaware, M. M. DAUGHERTY (*Delaware Sta. Bul. 199 (1936), pp. 24*).—Data are gathered from 120 part-time farmers in the low-income groups in New Castle County in January and February 1934 in cooperation with the Bureau of Agricultural Economics, U. S. D. A., using Civil Works Administration funds. Analysis is made of cash incomes, length of farming experiences, location, value and area of part-time farm, value of products, etc.; of the relation of size and farm expenses; of number of cultivated acres and expenses, etc. The average value of the farms studied was $3,460 and the average earning outside of farming was $752. The average farming experience of the farmers was 9 yr. and their average age 46.7 yr. Slightly over 50 percent of the farmers had been raised on farms. Two-thirds of the farmers owned their farms, which were about two-thirds paid for. Large families did not raise more products than small families, and families in the low-income groups did not raise more than those in the larger-income groups. Fifty-five percent of the farmers stated that one acre or less would be all the land desirable if they were relocated. The most important advantage of part-time farming was given as economy by men and as a better place to rear children by women. The average saving was about $28 per month.

"The facts, as presented in this bulletin, show that part-time farming is not highly profitable, and that the operation of such a farm is attended with

much work and some inconvenience. Yet most of the occupants find the balance to be in favor of part-time farming as contrasted to living in a city."

Cost of producing farm products in New Jersey (*New Jersey Stas. Rpt. 1935. pp. 7–9*).—Brief summaries are included of findings as to costs of production of milk, poultry, asparagus, corn silage, sweetpotatoes, onions, apples, and peaches.

Cost of production of sweet potatoes, compiled by H. W. HAWTHORNE (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. 16*).—This is a compilation of the findings in studies made in Arkansas, California, Georgia, Louisiana, Mississippi, New Jersey, New Mexico, South Carolina, Texas, and Virginia for the years 1914–32, inclusive, by the Department and the State agricultural experiment stations.

Cost of production and grove organization studies of Florida citrus, C. V. NOBLE, Z. SAVAGE, and B. MCKINLEY (*Florida Sta. Rpt. 1935, pp. 32, 33*).—A table is given showing the average costs, returns, and profits per acre, 1932–33, of grapefruit plantings made from 1918 to 1920.

The manufacture and use of California canned orange juice, H. J. STOVER (*California Sta. Mimeogr. Rpt. 45 (1936), pp. [1]+27, figs. 6*).—This is a preliminary report based chiefly on a survey of the manufacturers of orange byproducts in California made in February 1936. Tables and charts include data on orange production, shipments, and prices in the United States; the packs of orange and other fruit juices in California; the relation of canned orange juice to sales of fresh oranges and other canned fruit juices, etc.

Creamery operating efficiency in California.—III, Relation of creamery capacity to supply of milk fat in Humboldt County, J. M. TINLEY, F. H. ABBOTT, O. M. REED, and J. B. SCHNEIDER (*California Sta. Mimeogr. Rpt. 44 (1936), pp. [2]+75, figs. 13*).—This is the third of the series of reports previously noted (E. S. R., 74, p. 717). It deals mainly with the problems of external or environmental plant efficiency—the extent to which the combined capacity of all the plants in a particular area is coordinated with the supply of raw materials available in that area or with the actual or potential demand for the products of those plants.

"This part of the study is divided into several sections. The first enumerates some of the more important economic principles involved in a study of external plant efficiency. . . . The second section is concerned with an analysis of the historical development of dairying in the area selected for the study. This involves an analysis of natural forces, such as climate and rainfall, and of feed conditions and farming practices, that influence the establishment and continuance of dairying in that area. Consideration is given to the increase in cow numbers and the trend of milk fat production, as well as to the probable future trend of dairying. The third section deals with the historical development of plants, and the fourth with the measurement of capacity and the efficiency of utilization of such capacity. Special attention is given to the circumstances leading to the expansion of capacity within previously existing plants and in new plants. In the fifth and final section an attempt is made to trace the effects of overexpanded capacity upon operating costs per unit and the returns to investors in creameries and to producers of milk fat in the area selected for the study."

Price factors in the Los Angeles milk market, J. M. TINLEY (*California Sta. Mimeogr. Rpt. 48 (1936), pp. 41, figs. 8*).—This is a statement prepared for presentation at the hearing on July 8, 1936, on the proposed stabilization and marketing plan for the Los Angeles milk marketing area. It supplements and brings up-to-date the more significant tables and figures relating to producers'

prices in the bulletin previously noted (E. S. R., 65, p. 483) and analyzes the economic effects of some of the recent developments in the Los Angeles milk market.

Organization and operation of the Illinois Livestock Marketing Association, H. H. HULBERT (*Farm Credit Admin. [U. S.], Coop. Div., Bul. 5 (1936), pp. IV+140, figs. 12*).—The Illinois Livestock Marketing Association was established in 1931 to federate the cooperative livestock marketing units of the State "with a view to broadening the marketing program and coordinating the activities of livestock cooperatives throughout the State." The study reported on in this bulletin was made "in order to analyze the economic background of this organization and to appraise, so far as possible, the success of the association in accomplishing its objectives." The changed conditions affecting livestock cooperatives leading up to the formation of the association, the organization, financing, etc., of the association; its field service program; the local operating practices; the distribution of sales by the association; direct-to-packers sales; the returns from direct-to-packers and terminal-market sales; and the operating problems of the association are described and discussed.

Appendixes include the code of bylaws of the association; the marketing agreements between the association and individual livestock producers and county livestock marketing associations, and between county livestock marketing associations and individual producers; the report of a special committee on operating policies of the association; and detailed information on direct sales of hogs by the association.

An analysis of the prices received for canned apricots by canners in California: Seasons, 1924–25 through 1935–36, H. J. STOVER (*California Sta. Mimeogr. Rpt. 47 (1936), pp. 19, figs. 7*).—This analysis corresponds to that on peaches noted above.

An analysis of the prices received for canned clingstone peaches by canners in California: Seasons, 1924–25 through 1935–36, H. J. STOVER (*California Sta. Mimeogr. Rpt. 46 (1936), pp. 19, figs. 7*).—"This report presents the results of an analysis which has been made for the purpose of determining the more important factors which have been responsible for the variations in the annual average f. o. b. prices received for canned clingstone peaches by canners in California from 1924–25 through 1935–36, and of measuring the influence of each of these factors upon those prices."

Imports of agricultural products into the United States and estimated acreage displaced (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. 18*).—A table is included showing for different agricultural products the average imports minus reexports 1926–28, average yield per acre 1924–28, the estimated acreages displaced by net imports, and the tariff rates in 1922 and 1930.

Fats and oils, and the excise taxes of 1934 (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. [2]+16*).—Tables are included showing the tariff rates, May 1936, on different fats, oils, and raw materials; the imports, general 1929, 1932, and 1933, and for consumption 1934 and 1935 and January to March 1935 and 1936 of different fats, oils, and raw materials; stocks of primary fats and oils, December 31, 1931 to 1935, inclusive, and factory consumption in the United States by years 1931–35 of coconut oil and fats and oils used in manufacturing soap and oleomargarine and in the drying industries; and the prices of different fats and oils, 1929, by years 1932–35, and April 1935 and 1936.

Crops and Markets, [June 1936] (*U. S. Dept. Agr., Crops and Markets, 13 (1936), No. 6, pp. 177–216, figs. 3*).—Included are tables, charts, reports, summaries, etc., of the usual types.

RURAL SOCIOLOGY

Rural sociology, J. M. GILLETTE (*New York: Macmillan Co., 1936, 3. ed., pp. XXXIV+778, figs. 44*).—In this revision of work previously noted (E. S. R., 60, p. 387) the author minimizes suggestions for social improvement or reform and maximizes a factual study of rural society. The volume is divided into six parts. Part 1 deals with rural society and rural sociology; part 2, with ecological conditions; part 3, with biosocial conditions; part 4, with sociocultural conditions; part 5, with rural-urban relations; and part 6, with rural social progress—special phases.

[Investigations in rural sociology by the Michigan Station], E. MUNFORD (*Michigan Sta. Rpt. 1935, pp. 232–234*).—The progress results are briefly presented of studies of the influence on agricultural leadership of early life on the farm; an analysis of the nationality and other population groups in Michigan and of their contribution to agriculture and rural life; and the standard of living of farm families in relation to community advantages.

National policy and rural public welfare, E. L. MORGAN (*Rural Sociol., 1 (1936), No. 1, pp. 8–19*).—The author calls attention to county social work on a partial taxation basis in the States of Iowa, Massachusetts, and New York as the beginning of modern rural public welfare in this country. He states that "the immediate future should provide permanent Federal planning based upon democratic participation of State, county, and local units, preferably along patterns already established in other fields; permanent centralization of leadership in a Federal Department of Public Welfare; administrative responsibility allocated to States vested in a somewhat similar administrative unit; a permanent cooperative plan of financial aid to States on a matching basis similar to that provided by the Smith-Lever and Smith-Hughes Acts, in which the State could make grants to counties under prescribed conditions and in which funds originating in counties could be used as State offset in matching Federal funds; the establishment of professional standards in public welfare work; the encouragement of research in rural public welfare; and a thorough dissemination among rural people of the philosophy of modern public welfare."

National policies and rural social organizations, L. NELSON (*Rural Sociol., 1 (1936), No. 1, pp. 73–89*).—The author discusses the effect of recent policies on the social profile of the country. "Rural people, along with urban, find themselves confused by the collapse of traditional forms and the conflicting ideologies struggling for dominance. Which of these ideologies will prevail, and the kinds of social controls which will result, we must leave to our children to describe."

Some sociological implications of the agricultural adjustment program, O. D. DUNCAN (*Assoc. South. Agr. Workers Proc., 35 (1934), pp. 202–206*).—The author points out some of the probable implications of the agricultural adjustment plan with reference to (1) the farm population, (2) problems which may be raised in regard to rural social agencies, especially the church, the school, and poor relief, and (3) the farmer's standard of living.

Rural emergency recreation and future rural social planning, B. L. MELVIN (*Rural Sociol., 1 (1936), No. 2, pp. 214–220*).—The author discusses the successes and failures of leisure-time programs among rural people carried out through the efforts of the U. S. Works Progress Administration. He concludes that "the recreational programs fostered by the extension service and the emergency agencies have emphasized the fact that a large segment of the rural population is not engaged in farming. This nonfarming group may increasingly constitute a service segment of the rural population. Its place may

lie more and more in the field of leisure-time activities, including the providing of facilities as well as leadership. In this the emergency programs for recreation have pointed the way."

Yardsticks for social planning, S. P. BURKE and V. F. PARRY (*W. Va. State Planning Bd. Bul. 1 (1935), pp. 75, figs. 47*).—In this report the methodology by which plans proposed for the social and economic development of a community or a geographic area may be intelligently analyzed and relatively evaluated is presented.

Forms and problems of culture-integration and methods of their study, P. A. SOROKIN (*Rural Sociol., 1 (1936), No. 2, pp. 121–141*).—The author defines human culture as follows: "In the broadest sense it may mean the sum total of everything which is created or modified by the conscious or unconscious activity of two or more individuals interacting with one another or conditioning one another's behavior." He classifies the main form of the integration of culture elements into four basic types: (1) Spatial or mechanical adjacency, (2) association due to an external factor, (3) functional or causal integration, and (4) internal or logico-meaningful unity.

Social standards for southern farmers, C. E. ALLRED (*Assoc. South. Agr. Workers Proc., 34 (1933), pp. 32, 33*).—The author defines social standards as the measure of the fullness and satisfaction of life on the farm. He then applies this measure to southern farmers.

County organization for program planning in Virginia, B. L. HUMMEL (*Rural Sociol., 1 (1936), No. 1, pp. 90–93*).—The author concludes that "it seems from results already achieved that it is advisable to combine the county boards with the local committees, and to develop county advisory boards and planning committees on a general community rather than a commodity committee basis. . . . Rural social organization is still a confusion of problems in the State as a whole, but with this progress in agricultural extension organization and county planning, and with a great many instances where more comprehensive community programs have been developed, we feel that we have a basis for further progress."

Needed standards of living for rural resettlement: A survey of 290 families in the Crandon, Wis., Land Purchase Area, E. L. KIRKPATRICK (*Madison: Wis. Rural Rehabil. Div., Resettlement Admin., 1936, pp. [3]+62, figs. 5*).—"This study was planned and conducted under cooperative arrangement between the department of rural sociology, Wisconsin . . . Experiment Station; division of research, finance and statistics, Federal Emergency Relief Administration; and rural (rehabilitation) division, Wisconsin Emergency Relief Administration. With transferral to the Resettlement Administration in July 1935, the Wisconsin rural rehabilitation division assumed responsibility for completion of the study, including distribution of the results."

Regional comparison of rural standards of living in Tennessee, C. E. ALLRED, W. E. HENDRIX, and B. D. RASKOFF ([*Nashville*]: *Tenn. Works Prog. Admin., 1936, Rpt. 15, pp. III+36, figs. 25*).—In this report of a study conducted cooperatively by the Tennessee Experiment Station, the Federal Works Progress Administration, and the Tennessee Works Progress Administration, the areas of the State were divided into three groups for purposes of comparison.

The rural community in the United States as an elementary group, D. SANDERSON (*Rural Sociol., 1 (1936), No. 2, pp. 142–150*).—The author points to the locality group as one of the most obvious elementary forms of social organization next to the family. "The determination of the type of rural community structure which, with due consideration to existing and historical conditions, will be most satisfactory for rural social organization forms one of the major problems of rural reconstruction facing many countries today."

Localization of dependency in rural areas, J. O. BABCOCK (*Rural Sociol., 1 (1936), No. 1, pp. 28–39*).—The author concludes "that we need a more thoroughgoing synthesis of the many factors present in a problem of this kind than we, as social scientists, are accustomed to make. We find many questions only partially answered when we consider the problem of dependency."

Concentration of rural relief in certain localities in North Carolina, G. W. BLACKWELL (*Rural Sociol., 1 (1936), No. 2, pp. 200–218, fig. 1*).—From a study of problem localities in North Carolina, the author concludes "that many problem villages, communities, and areas can, and should be, reconstructed economically and socially. It will be a paying proposition from many viewpoints. The cost per family rehabilitated thereby will doubtless be less than the per-family cost in newly created, organized rural communities. In some instances, however, resettlement of some of the population of problem communities and areas will be necessary, but folkways must be reckoned with. Where the type of people is an outstanding difficulty, aid from the social work profession clearly is needed. Loss of industry in rural areas, lack of sufficient cultivable land, submarginality of land, and general agricultural problems appear primarily to be the concern of Resettlement Administration. Through the cooperation of various governmental agencies now existing, much can be done for the people in these rural localities with long-time problems."

Littleville: A parasitic community during the depression, C. C. ZIMMERMAN, J. H. USEEM, and L. H. ZIEGLER (*Rural Sociol., 1 (1936), No. 1, pp. 54–72*).—"This study of Littleville shows how an almost chronically parasitic community greatly improved itself during the recent depression. . . . Its organs for nonparasitic existence have atrophied from disuse, while those for collective exploitation of the outer world have been sharpened."

The study of the life cycle of families, C. P. LOOMIS (*Rural Sociol., 1 (1936), No. 2, pp. 180–199*).—"Studies of the family have given too little attention to the life cycle. . . . Of interest to students of population and students of the economic and social life of the family is the difference between the manner of adjustment of the city family, on the one hand, and the farm family, on the other, as the two different groups pass through their life cycles. The few studies in existence indicate that poorer city families must either restrict the number of children or reduce their material standard of living to bring children into the world. The farm family, on the other hand, has a somewhat better opportunity of increasing its income, through increased exertion on the part of adult members and in some instances of the small children who may aid considerably in supporting themselves long before they would approach self-sufficiency in the city. Data are presented which show that the whole social and economic life of rural families is different in various stages of the life cycle. Professor Sorokin and Russian authorities have delimited four stages in the life cycle of the family. Four similar stages in the life cycle of white North Carolina farm families were studied, and it was found that this analysis threw light on differentials in biological, economic, and social activity. Other studies made under other conditions and with the use of different methods agree with the findings of the North Carolina study in some instances and not in others."

Population mobility, C. E. LIVELY (*Rural Sociol., 1 (1936), No. 1, pp. 40–53*).—The author deals with the spatial and occupational mobility of the rural population of the United States. The movements of families and individuals by which they attempt to orient themselves geographically and occupationally are analyzed.

The anual rate of departure of rural youths from their parental homes, C. H. HAMILTON (*Rural Sociol., 1 (1936), No. 2, pp. 164–179, figs. 5*).—This paper

has presented a simple and practical method of measuring and analyzing the rates at which rural young people depart from their parental homes. The basic data needed for this type of study are very few and could be collected extensively and rapidly through simple enumerations of the population or in connection with other social studies. There is a relationship between the variations in departure rates and the economic status of the families involved, whether the economic status is measured by relief, color, tenure status, or the general income available. It has been shown in a number of studies that the standards of living of poor people are much more dependent on income than is the case of the well-to-do. It is not surprising, therefore, to find departure rates of rural youth following a similar pattern.

Rural young people face their own situation, E. L. KIRKPATRICK and A. M. BOYNTON (*Rural Sociol., 1 (1936), No. 2, pp. 151–163*).—A survey was made of Waushara County, Wis., in which 2,123 schedules were filled out by rural young people between the ages of 15 and 29, two-thirds of whom reside on farms and the remainder in villages of less than 2,500 population. The questions asked were: "What is known about these rural young people? Where do they live? What are they doing? How much schooling have they had? What choices of occupations do they have? To what extent does farming appeal to them? How are they using their spare time? What can be done to improve their situation? To what degree do they sense needs in the home community? And what opportunities do they see to improve local conditions?"

"Even though these results are preliminary, they indicate that young people recognize their situation and are aware of certain needs in the immediate localities. They show that young men and women are actually thinking of possible developments and indicate that they are rapidly becoming more eager to work out definite programs for the realization of specific objectives."

Size of family in relation to homogeneity of parental traits, W. C. MCKAIN, JR., and N. L. WHETTEN (*Rural Sociol., 1 (1936), No. 1, pp. 20–27*).—Data obtained from a survey of 1,816 families residing in the township of Windsor, a surburban area adjacent to the city of Hartford, Conn., led the authors to the conclusion that there is a positive correlation between the homogeneity of parents and the size of their families. They suggest, however, that the results obtained by them be tested by others.

Trade centers in Tennessee, 1900–1930, C. E. ALLRED, B. H. LUEBKE, and J. H. MARSHALL (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Rpt. 16 (1936), pp. III+30, figs. 10*).—This report pays particular attention to the number, size, and distribution of trade centers and to factors related to their appearance and disappearance, growth, and decline.

A survey of scenic and recreational resources of Utah, S. R. DE BOER and G. M. P. DOUGALL (*Salt Lake City: Utah State Planning Bd., 1936, pp. [5]+106, figs. 17*).—"This report deals primarily with the basic data gathered on the scenic and recreational resources to be found in Utah, the laws affecting existing and future development of these resources, and comparisons of Utah tourist travel with other States."

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Health service in secondary schools of Idaho (*Idaho Sta. Bul. 220 (1936), p. 25*).—Results from a questionnaire sent 37 high schools are briefly noted.

A manual for 4–H poultry club members, H. H. ALP and E. I. PILCHARD (*Illinois Sta. Circ. 452 (1936), pp. 31, figs. 14*).—The Illinois plan for 4–H poultry club work is outlined and the fundamentals of poultry production and management explained.

FOODS—HUMAN NUTRITION

President's address: Research and our food industries, F. C. BLANCK (*Jour. Assoc. Off. Agr. Chem., 19 (1936), No. 1, pp. 34–38*).—This paper from the U. S. D. A. Bureau of Chemistry and Soils is a general discussion of the relation of research to the food industries such as canning; meat; jams, jellies, and preserves; dairying; and the frozen pack industry, and of the progress made in the field of food containers. Research in the food field is discussed with reference to unsolved food problems such as the nature, cause, and prevention of rancidity; the nature of the color and the flavor of natural foods; the ash constituents of American foods; utilization of waste and refuse material incident to food packing; and the effect of light on the composition, color, and physical consistency of manufactured foods.

[Food and nutrition studies by the Florida Station] (*Florida Sta. Rpt. 1935, pp. 70–72, 130, 131*).—In this annual report summaries, some of which are extensions of previous work (E. S. R., 72, p. 413), are included by C. F. Ahmann on the relation of growth to phosphorus, calcium, and lipin metabolism as influenced by the thymus; by O. D. Abbott on the study of lecithin synthesis in hens on a vitamin A- and lipoid-free diet and on a study of the hematopoietic tissues of rats on a diet low in vitamin A; by L. W. Gaddum on a study of the chemical composition of the more unusual constituents of the ash of Florida fruits and vegetables; by Abbott on an investigation in Alachua County, with special reference to nutritional anemia in relation to the composition of home-grown foods; by Ahmann on the pharmacological action of papain; and by F. D. Stevens and J. R. Neller on sugarcane sirup and sugarcane-citrus sirup blends.

A study of winter food consumption in Wisconsin farm families, M. L. COWLES (*Jour. Amer. Dietet. Assoc., 11 (1935), No. 4, pp. 322–330, figs. 2*).—For this food consumption study 109 rural families representing high, medium, and low incomes per farm were selected from three Wisconsin counties. The weekly average cost of the food consumed by these families was found to be $10.01, or $2.29 per adult male; 32 percent was bought and the remainder furnished by the farm. As the number in the family increased, the expenditure for food per adult male unit decreased.

A computation of the calories, protein, iron, calcium, and phosphorus of 1 week's food consumed by 57 of the families was made and compared with requirements for energy, protein, and minerals as indicated by the scales prepared by Hawley Iron was found to be deficient in the largest number of diets. Phosphorus and calories were markedly deficient, and calcium was low in some of the diets. Protein requirements were adequately met in most of the diets due to the intake of meat and milk furnished by the farm. There was apparent a possible deficiency in vitamins B and C due to the low intake of vegetables and citrus fruits and to the use of highly refined cereals. Of the total diets, 31.6 percent showed some deficiency.

Diets became more adequate as the cost for food increased, due to the quantity rather than the judicious selection of food. A week's diet costing $2.40 per adult male unit showed no deficiency.

Relative economy of different forms of milk as sources of protein, calcium, and phosphorus, M. M. KRAMER and B. L. KUNERTH (*Jour. Amer. Dietet. Assoc., 11 (1935), No. 4, pp. 318–321, fig. 1*).—In this contribution from the Kansas Experiment Station, the total grams of protein, calcium, and phosphorus in 1 qt. of fresh whole and skim milk, 1 lb. of dried whole and fresh milk, and a can containing 14.5 oz. of evaporated milk are compiled in table form, together with their cost per gram.

Problems of poultry cookery, B. LOWE (*U. S. Egg and Poultry Mag., 42 (1936), Nos. 5, pp. 272, 273; 6, pp. 336, 337, 383, 384*).—Certain aspects of poultry cookery differing from general meat cookery are given in this paper. Criteria which determine palatability and factors that influence cooking temperatures are discussed from the standpoint of poultry cookery.

Preparation of the birds for cooking is discussed with reference to the effect of rigor mortis, temperature and length of time in storage, acidity in the muscles, and freezing and freezer burns on the palatability, particularly tenderness, and on the cooking losses. The treatment of drawn poultry with carbon dioxide is recommended as a treatment against bacterial contamination and spoilage. Palatability as affected by cooking methods is discussed from the standpoint of cooking before or after defrosting, in covered or uncovered pans, and of high or low temperatures, of fat distribution, and of the effect of basting with fat on the texture of the skin when the poultry is cooked uncovered. Suggested problems in poultry cookery to be worked out by a physiological or a biological chemist are the types and kinds of meat proteins, their properties such as solubility, ability to hold moisture, and coagulability, and the effect of salt, acids, and alkalies on these and the nature of flavor.

A study of the nutritive value of mushrooms, F. W. QUACKENBUSH, W. H. PETERSON, and H. STEENBOCK (*Jour. Nutr., 10 (1935), No. 6, pp. 625–643, figs. 5*).—Feeding experiments with rats by the usual technic at the Wisconsin Experiment Station gave evidence that the mushroom *Agaricus campestris* incorporated in the diet in a dried state reduced the food intake and consequently the growth by from 40 to 45 percent in some cases, thereby hampering the investigation. No such effect was observed when mushrooms were fed to animals depleted of vitamins B and G. The authors discussed the possible causes for the difficulty, such as toxicity, indigestibility, and dilution of the ration, but arrived at no satisfactory explanation.

Levels of 5 and 10 percent of dried mushrooms supplied sufficient vitamins B and G to support satisfactory growth. Diets containing 10 percent of mushrooms as a source of vitamin B point to a deficiency other than B and G.

The data on the mushroom protein were preliminary and incomplete.

A study of culinary quality in white potatoes, J. S. COBB (*Amer. Potato Jour., 12 (1935), No. 12, pp. 335–346*).—This contribution from the Pennsylvania Experiment Station covers experimental work from 1929 to 1933.

The external tuber characteristics were not found to be a reliable index of quality except that small ill-shaped or immature potatoes were observed to have poor quality. Good cooking quality was closely associated with high starch and dry matter content of the tuber and low nitrogen content. Baked potatoes gave higher quality scores than boiled ones of the same lot. A large number of tests showed a 25 percent loss of weight due to loss of water during baking, while boiling gave neither loss nor gain of weight.

Lower temperatures, sufficient rainfall, and the variety favored better quality potatoes. The higher altitude with a lower average temperature and with rainfall no greater than at lower altitudes produced better quality potatoes. Any type of soil, heavy silty clay type, or gravelly or shaly type seemed to grow good potatoes. No distinctly potash-deficient soil was used in any test, but all fertilizer treatments used improved the yields and quality.

Beverages from rhubarb, W. F. WALSH and D. K. TRESSLER (*Fruit Prod. Jour. and Amer. Vinegar Indus., 15 (1936), No. 9, pp. 262, 263*).—The method developed at the New York State Experiment Station for preparing juices from rhubarb used thoroughly washed tender, succulent stalks which were shredded and pressed with a hydraulic press. The yield varied from 60 to

75 percent of their weight as juice. The juice was clarified after heating to 120° F. by flocculating the small particles of cellular debris in suspension with the pectic enzyme preparation Pectinol A and by filtering. Since excessive amounts of the soluble potassium oxalate present in the juice are undesirable, the oxalate was removed by treatment with calcium carbonate at 180°, and the juice then chilled at from 32° to 40° to precipitate the insoluble calcium oxalate, and filtered. The resulting juice was described as brilliantly clear and remained in this condition and retained its rhubarb flavor during nearly a year's storage.

The total acidity of the juice, expressed as malic acid, ranged from 1 to 1.7 percent, depending upon the variety and maturity of the stock. The Victoria and Strawberry varieties were found to be excellent stock for juice purposes, the Pineapple variety lacked a characteristic flavor, and the Ruby variety was used advantageously for its red color which was imparted to the juice.

Rhubarb juice was found pleasing to the palate in plain and carbonated beverages in which it was diluted with water to reduce the total acidity to from about 0.7 to 0.8 percent and sweetened with sufficient cane sugar to bring the total solids content to 14 percent as read on the Brix scale. It was also found suitable as a blender with other fruit juices such as sweet, insipid cider, Montmorency cherry juice, Concord grape juice, and citrus and berry juices.

Factors which affect the quality of canned tomatoes.—I, A study of the physical and chemical constituents of Arkansas Marglobe tomatoes, M. E. SMITH (*Fruit Prod. Jour. and Amer. Vinegar Indus., 15 (1935), Nos. 3, pp. 81–83, 91, figs. 2; 4, pp. 114, 115, 122, fig. 1*).—In this report of an investigation at the University of Arkansas, the effect of temperature and precipitation is shown on the canning qualities of tomatoes. Marglobe tomatoes grown on the experimental farm were canned at various intervals from June 28 to August 6, 1934. Climatic conditions during the growing season were recorded.

The season was hot and dry and unfavorable to growing tomatoes of high quality. Sunscald was the principal defect, followed by catfaces and other minor blemishes. The fruit ripened unevenly to the extent that a large amount was unripe at every picking. This unripe fruit allowed to ripen under cover compared favorably, however, with the field-ripened fruit.

The results show that when the temperature was highest the acidity of fresh and canned tomatoes was highest and the total solids and the yield per pound were lowest. Also, at maximum temperatures the amount of invert sugar was high, resulting in substandard quality packs. An exception was the pack on August 6, when previous precipitations improved the quality of the flesh and flavor.

Charts are given showing the yield of fresh fruit per can per pound, percentage of total solids, the pH of fruit and canned fruit juices, and invert sugars, as well as tables showing the results of the physical tests and chemical analyses.

Preservation of fruits and vegetables by freezing, E. H. WIEGAND (*Oregon Sta. Circ. 116 (1936), pp. 12*).—In this circular information is given on the methods of packing, freezing, and storing fruits and vegetables. The best temperatures for freezing are considered to be from 5° F. below zero to 10° above zero and for storage from 10° to 15° above zero. Uniform temperatures during freezing and storage may be maintained with fans and adequate insulation and are important to prevent losses through mold growth and development of unpleasant flavors.

Sugar used dry or in solution in the ratio of 3 parts fruit: 1 part sugar improves the fruit and decreases oxidation processes. Vegetables are packed either well-drained or in a 2-percent brine. Leaving from ½ to 1 in. space

at the top of a filled container allows the liquid and products to expand during freezing. Rapid freezing is important to prevent color changes and improves and retains the important flavors of the food. The cooking time for frozen products should be reduced to half the normal cooking for the fresh product. Frozen vegetables without brine should be placed in boiling water and allowed to cook until soft. Vegetables with brine should be allowed to thaw and then cooked in the brine.

Special methods of preparation are described and tabulated for blackberries, blueberries, cranberries, loganberries, black and red raspberries, strawberries, Youngberries, black, sour, and white cherries, apricots, figs, grapes, peaches, prunes, asparagus, green and wax beans, lima beans, broccoli, cauliflower, sweet corn, mushrooms, peas, and spinach.

Effect of storage, freezing, and canning on the nutritive value of vegetable products, C. R. FELLERS and P. D. ISHAM (*Veg. Growers Assoc. Amer. Ann. Rpt., 1935, pp. 85–97*).—This contribution from the Massachusetts Experiment Station gives statistics showing that the greater percentage of the 1933 vegetable crop was used for manufacture, such as canning, freezing, pickling, and dehydration and a table indicating the chemical composition, including vitamin content, of the edible portion of fresh vegetables. The effects of shipping, storage, freezing, and canning have been mainly noted above. The effects of dehydration were losses through destruction of vitamins B and C and to some extent vitamin A. Sulfuring, a process applied only to dried fruits, tended to retain vitamins A and C. The manufacture of kraut and pickles, a process of fermentation, converted the vegetable sugars into lactic acid which resulted in some loss of vitamin C through destruction and of minerals through solution in the brine. The various losses through processes of manufacture were not considered serious in view of the large portions of vegetables used in the American diet.

Bacteriological problems involved in the home canning of foods, C. C PROUTY (*Northwest Sci., 10 (1936), No. 2, pp. 9–11*).—This contribution from the Washington Experiment Station emphasizes the importance in home canning of using processing methods which designate such temperatures, period of exposure, and equipment as to insure destruction of the spores of *Clostridium botulinum* and other bacteria causing spoilage, especially for the nonacidic vegetables and meat products. Certain thermophilic bacteria are not destroyed by either commercial or home processes. To prevent the growth of these organisms canned goods should be stored at a low temperature. Boiling temperature for nonacidic fruits and vegetables and meat products destroys the botulinus toxin.

[Bacteria in sugar], W. V. HALVERSEN (*Idaho Sta. Bul. 220 (1936), p. 25*).—Tests of 13 samples of sugar for thermophilic bacteria are noted.

[Bacterial studies], W. L. MALLMANN (*Michigan Sta. Rpt. 1935, pp. 207–210*).—Investigations are reported in detail as to the spoilage of frankfurters and restaurant sanitation.

Detection and significance of Escherichia coli in commercial fish and fillets, F. P. GRIFFITHS and J. E. FULLER (*Amer. Jour. Pub. Health, 26 (1936), No. 3, pp. 259–264*).—This cooperative study by the U. S. Bureau of Fisheries and the Massachusetts Experiment Station dealt with the occurrence of bacteria of the coli-aerogenes on 20 commercial haddock fillets and 5 eviscerated haddock purchased from the local retail market. *E. coli* was identified to investigate the possibility of using its occurrence as an index of the sanitary quality of fish. Typical *E. coli* were found on 16 fillets and 2 eviscerated fish. Differential tests indicated the presence of lactose-fermenting bacteria other than the *E. coli*.

Basal metabolism of Wyoming University women, E. J. McKittrick (*Jour. Nutr., 11 (1936), No. 4, pp. 319–325*).—This investigation was undertaken at the Wyoming Experiment Station to determine the basal metabolism of 100 normal young women between the ages of 17 and 26 yr., most of whom had lived in Wyoming more than 10 yr. The usual procedure of determining basal metabolism was followed. Deviations from the standards of Aub-Du Bois, modified by Boothby and Sandiford, and of Harris-Benedict were calculated and found to average —3.18 and —2.54 percent, respectively. These metabolic rates were higher than those previously found by Tilt and Walters (E. S. R., 74, p. 130) in Florida and Coons (E. S. R., 66, p. 890) in Oklahoma, determined under similar conditions. These results indicate that the higher altitude of Wyoming, as compared to that of Florida and Oklahoma, speeds up the metabolic rate.

A table gives the basal metabolism values and deviations from the standard for each of the 100 women.

The energy requirement of farm women, N. B. Morey (*Jour. Home Econ., 28 (1936), No. 1, pp. 38–44*).—This is a report of an investigation made at the [New York] Cornell Experiment Station. "The energy requirements of farm women have here been estimated from time studies and figures for energy expended per kilogram per hour in various activities, and have been compared with the energy intake of farm women as shown by studies of individual women. The results derived from both methods of study point to an average energy requirement of about 2,500 to 2,600 calories per day for farm women not regularly engaged in actual farm labor. Similar comparisons for town and city women indicate a smaller energy requirement, about 2,200 to 2,300 calories, for the average town or city housewife. The dietary scales and standards in general use in this country make an allowance of 2,700 to 3,000 calories for farm women and about 2,400 to 2,500 calories for the woman 'at moderately active work', which is usually interpreted to mean ordinary housework. It seems, therefore, that these scales and standards tend to overestimate the energy needs of women generally."

The relation of the rate of growth to diet.—III, A comparison of stock rations used in the breeding colony at the Connecticut Agricultural Experiment Station, L. B. Mendel and R. B. Hubbell (*Jour. Nutr., 10 (1935), No. 5, pp. 557–563, fig. 1*).—In this paper of a series from the Connecticut [New Haven] Experiment Station and Yale University, a comparison is made of the growth, the reproductive performance, and the diet of the albino rat during three periods of history of the stock colony at the station. Observations for the first two periods were noted previously (E. S. R., 56, p. 191; 67, p. 772).

The ration in use at the time of writing was calf meal and cod-liver oil reinforced in vitamin D, and in addition nursing mothers and young rats under 6 weeks of age received a paste food consisting of casein, whole milk powder, wheat embryo, and lard. This ration was supplied ad libitum and supplemented with 1 g dried yeast per rat per day. Those rats not receiving the paste food were given 3 g of wheat embryo per week.

Data for the colony at different periods in its history afford evidence of the effectiveness of the present ration for reproduction, as judged by the number and size of litters, percentage weaned, and weights of the young at birth and at weaning. A marked increase in growth of both male and female rats was noted following the change in the ration in 1931 to one richer in protein and using definite amounts of dried yeast and wheat embryo, which were fed separately.

The utilization of energy producing nutriment and protein as affected by individual nutrient deficiencies.—III. The effects of the plane of protein intake, E. B. FORBES, R. W. SWIFT, A. BLACK, and O. J. KAHLENBERG (*Jour. Nutr., 10 (1935), No. 5, pp. 461–479, figs. 7*).—This investigation, conducted at the Pennsylvania Experiment Station, repeated as nearly as practicable the experiments and procedure of study reported in two earlier papers previously noted (E. S. R., 72, p. 371; 73, p. 414).

"The effects of the increasing protein content of the equicaloric diets were as follows: Increase in gain in body weight at decreased cost in terms of dry matter of food; increase in efficiency of digestion and retention of protein and of energy-producing nutrient; increase in urinary nitrogen at an increasing rate and increase in protein of the body at a decreasing rate; increase in energy of the urine coincident with decrease in the energy of the feces, the metabolizable energy, therefore, remaining practically constant; diminished efficiency in the utilization of food nitrogen; no regular change in amount of fat gained, but usually a decrease in fat gained in proportion to protein gained.

"Increases in the protein of equicaloric diets having the effect to improve their nutritive balance made no change in the basal heat production per unit of computed surface area, but diminished the total heat production of the animals, as they lived under normal conditions of freedom of activity."

Feeding experiments with mixtures of highly purified amino acids, VII, VIII (*Jour. Biol. Chem., 112 (1935), No. 1, pp. 275–302, figs. 3*).—In continuation of the series noted previously (E. S. R., 73, p. 270), two papers are presented.

VII. *The dual nature of the "unknown growth essential"*, M. Womack and W. C. Rose (pp. 275–282).—The unknown growth essential was separated into two components by their difference in solubility in aqueous butyl alcohol. The more soluble one was identified as isoleucine by deductions made from the growth responses in rats fed isoleucine and the less soluble component.

VIII. *Isolation and identification of a new essential amino acid*, R. H. McCoy, C. E. Meyer, and W. C. Rose (pp. 283–302).—The second component was isolated in pure crystalline form and identified as α-amino-β-hydroxy-*n*-butyric acid. Approximately 0.6 percent of the amino acid was required to promote good growth in rats on a diet furnishing 18 percent of effective amino acids.

These experiments are the first to successfully induce growth in animals receiving mixtures of purified amino acids in place of protein.

Hydroxyglutamic acid and citrulline were found to be nonessential for growth.

Synthesis of α-amino-β-hydroxy-n-butyric acids, H. E. CARTER (*Jour. Biol. Chem., 112 (1936), No. 2, pp. 769–773, fig. 1*).—The α-amino-β-hydroxy-*n*-butyric acid, noted above, was synthesized according to the method described by Abderhalden and Heyns.[3] The synthesized substance had no growth-promoting properties even when fed at high levels. It was converted into a mixture of two possible epimers by heating the formyl derivative prepared by the method of Du Vigneaud and Meyer[4] with sodium hydroxide and acetic anhydride and hydrolyzing with concentrated hydrobromic acid. This mixture incorporated in a diet containing all the known amino acids except hydroxyglutamic promoted the growth of rats.

Enzymic digestion of lactalbumin versus casein in vitro, M. C. KIK (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 2, pp. 194–196*).—This study, made at the University of Arkansas, followed the technic of Sure et al. (E. S. R., 74, p. 743) of digesting in vitro three concentrations, 120, 180, and 210 mg, of casein

[3] Ber. Deut. Chem. Gesell., 67 (1934), No. 4, pp. 530–547.
[4] Jour. Biol. Chem., 98 (1932), No. 2, pp. 295–308.

and lactalbumin by trypsin and erepsin present in pancreatic and intestinal extracts of rats. The rate of digestion was followed by the percentage of amino nitrogen liberated. The results show casein to be more readily digested than lactalbumin under similar conditions.

A summary of the tryptic-ereptic digestion of the two proteins is given in a table.

The substitution of dithioethylamine (cystine amine) for cystine in the diet of the white rat, H. H. MITCHELL (*Jour. Biol. Chem., 111 (1935), No. 3, pp. 699–705*).—With the use of the paired feeding method the growth-promoting properties of cystine amine have been compared with cystine. Contrary to the evidence obtained by Sullivan, Hess, and Sebrell (E. S. R., 66, p. 389) from the ordinary ad libitum feeding indicating that cystine amine is capable of replacing cystine, the paired feeding tests show that cystine amine is not only incapable of replacing cystine in the diet, but definitely depresses the growth-promoting value of a cystine-deficient diet and impairs the appetite of the animal consuming it.

Commenting upon the paired feeding method with restriction of food consumption, the author states that "a severe restriction of food intake in a paired feeding experiment does not invalidate the comparison of rations; it merely delays the appearance of the effects of differences in nutritive value."

The effect of cereal diets on the composition of the body fat of the rat, H. S. OLCOTT, W. E. ANDERSON, and L. B. MENDEL (*Jour. Nutr., 10 (1935), No. 5, pp. 517–523*).—This contribution to the literature on the character of body fat as modified by diet deals with the character of fat produced by rats on rations in which the cereal grains corn, oats, wheat, and barley were each fed at levels furnishing 82 percent of the total energy value of the ration. The oil content of the cereals was such that the oil of corn supplied 8 percent, oats 10, wheat 3, and barley 4 percent of the total calories of the ration. The body fats produced on the various rations had iodine numbers of 33, 79, 70, and 71, respectively. The fats of the animals receiving wheat and barley were similar in character to the fat obtained from animals fed fat-free diets. The unsaturated fatty acids ranged from about 75 percent of the total body fat in the corn-fed animals to between 68 and 70 percent of the fat of the barley-fed animals. "The results suggest that some of the food unsaturated fatty acids are stored in preference to 'synthetic' fat when the food fat exceeds a certain minimal level, which level might be dependent upon the degree of unsaturation of the dietary fat."

Physiological effects of pituitary growth hormone: Growth and efficiency of food utilization, H. W. NILSON, L. S. PALMER, and C. KENNEDY (*Amer. Jour. Physiol., 111 (1935), No. 2, pp. 341–351, figs. 4; abs. in Minnesota Sta. Rpt. 1935, pp. 34, 35*).—In this study the strains of rats previously described (E. S. R., 70, p. 420) were used to determine the effect of injecting 1 cc of antuitrin G, a preparation of the pituitary growth hormone, on food utilization and growth rate. Growth was determined by weekly period changes, graphical analysis of group growth rate data, and statistical evaluation of mean group weights.

The results indicated that the hormone increased the growth rate and the efficiency in dry matter utilization within certain inherent limits which were controlled by sex and genetic factors. Females made a greater response than males. Rats having a low efficiency of food utilization responded more definitely to the hormone injection than those having a higher efficiency, but never attained the higher efficiency level. The increase in efficiency was not accompanied by increased digestibility. Water consumption was closely corre-

lated with dry matter intake, although it was not specifically increased by the growth hormone. Changes in live weight of rats were found to be satisfactory indexes for true growth, as indicated by chemical analysis on the carcasses of female rats having a low efficiency of food utilization after injections of the hormone. These analyses showed a decrease in the dry matter and fat content of the body tissues.

Some effects of cod liver oil and wheat germ on the retention of iron, nitrogen, phosphorus, calcium, and magnesium during human pregnancy, C. M. and R. R. COONS (*Jour. Nutr., 10 (1935), No. 3, pp. 289–310, fig. 1*).—As a supplement to the extensive investigation at the Oklahoma Experiment Station on the metabolism of pregnancy (E. S. R., 73, p. 715), a special study was made of the effect of cod-liver oil as a source of vitamins A and D and a wheat germ preparation as a source of the vitamin B complex on the retention of calcium, phosphorus, nitrogen, and iron during the latter part of pregnancy. The study, which was conducted on one subject, covered 101 days of continuously regulated diet during 82 days of which the diet was weighed. The retention of iron was improved by the wheat germ preparation and this was also true of nitrogen. Cod-liver oil enhanced this effect, but improved the retention of calcium, phosphorus, and magnesium only slightly. The subject purposely kept out of the sunlight during the entire period of study. As the retention of calcium was much lower than reported in earlier studies on a group of women receiving as much sunlight as possible during pregnancy, it was concluded that exposure to sunlight is more effective than cod-liver oil in conserving the much needed calcium.

Hydremia as a factor in the anemia of pregnancy, H. FELDMAN, E. C. VAN DONK, H. STEENBOCK, and E. F. SCHNEIDERS (*Amer. Jour. Physiol., 115 (1936), No. 1, pp. 69–77, figs. 2*).—Blood samples from 20 patients on relief rolls were taken at intervals during pregnancy and after parturition, and determinations made on the blood constituents, percentage of total proteins, and percentage of water. It was noted that blood showed a progressive anemia for 180 days or longer before parturition as indicated by a fall of hemoglobin values, cell volume, and refractive index and a simultaneous increase in water content. The reduction of protein content was less marked than the other blood constituents. The data are similar to those obtained with the pregnant rat (E. S. R., 73, p. 282).

The blood of 40 cows before and after parturition was studied, following the same procedure as with human blood, but showed very little change during pregnancy.

Some observations on the physiological adjustment of the albino rat to a diet poor in salts when edestin is the source of dietary protein, P. P. SWANSON, G. H. TIMSON, and E. FRAZIER (*Jour. Biol. Chem., 109 (1935), No. 2, pp. 729–737*).—This investigation at the Iowa State College presented evidence that a ration poor in salts and containing casein as the source of protein had a specific erythropoietic effect on the blood of the rat. When the casein was replaced by edestin, a globulin, no drastic increase in erythrocytes was noted, but a severe diuresis accompanied by increased consumption of water developed.

Trace elements in nutrition, C. A. ELVEHJEM (*Jour. Home Econ., 28 (1936), No. 2, pp. 111–117*).—This paper from the Wisconsin Experiment Station reviewed recent studies on the significance of minute quantities of iron, copper, manganese, cobalt, and zinc in the diet and on the availability of iron, including a table on the percentage of available iron as determined by the *a*adipyridyl method in 16 food materials. The addition of small amounts of the trace elements to the diet in cases of detected deficiencies is discussed. A list of 35 references is given.

A study of iron metabolism with preschool children, L. ASCHAM (*Jour. Nutr., 10 (1935), No. 3, pp. 337–342*).—This contribution from the Georgia Experiment Station reports iron balance studies conducted for five 3-day periods on 6 normal institutional children (4 boys and 2 girls), ranging in age from 4 to 6 yr. and in weight from 17.1 to 19.3 kg. Although there were a few negative balances in single periods, the average balances for each child for the entire 15 days were positive, ranging from 0.01 to 0.15 mg per kilogram of body weight on iron intakes ranging from 0.55 to 0.64 mg daily.

It is noted that the iron requirement, as indicated by the data obtained, is in fair agreement with the standards proposed by Daniels and Wright (E. S. R., 73, p. 564) and by Rose et al. (E. S. R., 65, p. 290), but higher than the allowance of Leichsenring and Flor (E. S. R., 67, p. 475). It is suggested that some of the differences in retention reported by different investigators may be due to differences in the availability of iron in the foods used.

The banana as a source of iron for hemoglobin formation, M. C. SMITH and L. OTIS (*Jour. Home Econ., 28 (1936), No. 6, pp. 395–398, fig. 1*).—This investigation, made at the Arizona Experiment Station, determined the availability of iron for hemoglobin formation by biological tests with anemic rats according to the method of Elvehjem and Kemmerer (E. S. R., 67, p. 90) and by the chemical $\alpha\alpha'$dipyridyl method of Hill (E. S. R., 64, p. 712). Banana powder was fed in place of fresh bananas at the maximum level of 4 g daily. This amount contained 0.098 mg of iron, which was considerably below the 0.3 mg of iron level used by Elvehjem et al. Four groups of nutritionally anemic rats were fed diets supplemented, respectively, with 4 g banana powder, with 4 g banana powder and 0.05 mg copper as copper sulfate, with 0.098 mg iron as iron chloride and 0.05 mg copper, or with 0.3 mg iron and 0.05 mg copper.

The average 6-week gain in hemoglobin on the supplemented diets in the order named above was 4.3 g per 100 cc of blood, 6.1 g, 6.5 g, and 9.6 g. These results indicated that copper was the limiting factor in the banana for complete utilization of the iron. The chemical dipyridyl method indicated the iron in the banana to be from 90 to 100 percent available. Difficulty was encountered in comparing the red color developed in the banana powder by this method with the standard because of a persistent yellow tinge even after bleaching and of adsorption of the red color on the protein fraction. Repeated washings were found necessary to approximate complete removal of the adsorbed color.

The food value of ethyl alcohol, H. H. MITCHELL (*Jour. Nutr., 10 (1935), Nos. 3, pp. 311–335; 5, p. 459*).—In this reinvestigation of the subject the general plan followed was "to feed pairs of rats equal quantities of a good basal diet and to give to one rat of each pair variable supplements of 95 percent alcohol. The nutritive effects of the alcohol were measured by determining the growth rates of pair mates over a number of weeks of this regime and by investigating the nitrogen and energy contents of the tissues formed from an analysis of the carcasses. The observed effects of alcohol were compared with the nutritive effects of sucrose determined in an entirely similar fashion, supplements of sucrose replacing supplements of alcohol. The comparative effects of alcohol and sucrose supplements upon the digestive processes were also studied by chemical examination of the feces of such paired rats." From the data reported the following conclusions are drawn:

"The energy of ethyl alcohol is to a large extent available for physiological purposes. Added to a complete diet, such as milk, it induces more rapid growth and a greater retention of nitrogen as well as of fat. The new tissue traceable to the alcohol supplement possesses a greater content of fat than that produced on the basal diet alone. The alcohol supplement does not increase the

excretion of metabolic products in the feces, but probably does increase the digestibility of the basal diet.

"As compared with a similar supplement of sugar, the energy of an alcohol supplement is only about three-fourths as available for physiological purposes, probably because of a greater specific dynamic effect. Its growth-promoting power is definitely less, though the composition of the new tissues produced is similar to that of the gains in weight produced by a sucrose supplement. Its effect on digestion is quite different from that of a sucrose supplement, the latter exerting no appreciable effect on the digestibility of the basal diet, but inducing a greater excretion of metabolic products in the feces in accordance with its content of dry matter."

A correction to certain of the computations in the main paper is made in the supplementary note.

[Vitamin investigations], E. Woods (*Idaho Sta. Bul. 220 (1936), pp. 34, 35*).—Included in this annual report are summaries of continued studies (E. S. R., 72, p. 137) on vitamin G in Netted Gem potatoes and on vitamin C in fresh, cold stored, and frozen prunes (E. S. R., 74, p. 132), and on the procedure for determining the vitamin G value of foods.

A biological appraisal of vitamins in the rural school child's winter diet, A. P. Brown (*Utah Acad. Sci., Arts, and Letters, Proc., 12 (1934–35), pp. 143–152, figs. 2*).—Food consumption records had been collected by the author at the Utah Experiment Station, as noted previously (E. S. R., 74, p. 417). A diet similar to the average diet taken by the school children was made up weekly and fed to guinea pigs and rats to test for vitamins.

Severe scurvy was produced in guinea pigs in from 3 to 4 weeks' time by use of the diet, indicating that numbers of the children might suffer from the latent or subacute form of the disease. Protection against scurvy in the guinea pig was given by daily additions of 3 cc. of orange or commercially canned tomato juice.

The dearth of vitamin C in the diets of these children is believed to have been due to lack of information or to indifference, since 17 fruits and vegetables known to be good sources of vitamin C were commonly grown in the counties in which these studies were made and can be canned and stored without materially destroying vitamin C.

The diet fed to rats maintained a slow steady growth, but was improved as indicated by growth with the additions of vitamins A and D, A, D, and B, and especially by A, B, D, and G.

The vitamin content of canned pineapple juice, N. B. Guerrant, R. A. Dutcher, F. S. Tabor, and R. Rasmussen (*Jour. Nutr., 11 (1936), No. 4, pp. 383–390*).—In this paper, a contribution from the Pennsylvania State College, pineapple juice was assayed by standard biological methods for its content of vitamins A, B, C, and G. It was found that 1 oz. of this juice contained approximately 30 Sherman units of vitamin A, 20 Sherman units of vitamin B, 2.5 Sherman units of vitamin G, and 40 international units of vitamin C. This assay shows pineapple juice to be a good source of vitamins A and B.

The relative vitamin A potency of carotene fed in butter fat and cottonseed oil, H. R. Kraybill and C. L. Shrewsbury (*Jour. Nutr., 11 (1936), No. 2, pp. 103–110, figs. 3*).—In this study from the Indiana Experiment Station, butterfat, decolorized with Lloyd's reagent until practically all color and vitamin A potency were removed, was tested as a carrier of carotene in comparison with refined cottonseed oil. Varying doses of carotene in the decolorized butterfat and in the cottonseed oil were assayed for vitamin potency.

It is concluded that carotene dissolved in the decolorized butterfat was not utilized as well as when it was dissolved in cottonseed oil, two or three times

as much carotene being required in the former to give equal vitamin A potency. It is pointed out that treatment of the butterfat with Lloyd's reagent removes the natural yellow pigments and vitamin A without noticeably destroying or removing the natural antioxidants. Data are also presented to show that hydroquinone, frequently used as an antioxidant, does not seriously interfere with the utilization of carotene from cottonseed oil.

Salivary secretion and the physiological mechanism of avitaminosis-A, H. C. CAMERON (*Amer. Jour. Physiol., 115 (1936), No. 1, pp. 210–214*).—In this study at the West Virginia Experiment Station, a slight temporary increase in salivary secretion, followed by a decrease, was noted in dogs with a salivary fistula during progressive stages of vitamin A deficiency when pilocarpine was used as a stimulus to secretion. Food when used as a stimulus caused very small changes in salivary secretion, indicating little or no change in the unconditioned reflex arc. Water consumption showed a temporary increase, followed by return to normal, particularly after the use of pilocarpine, suggesting a temporary central stimulation rather than a dehydrating effect due to avitaminosis A.

"Changes in salivary secretion are too small to serve as an index to circulatory or secretory changes occurring in avitaminosis A."

Cataract- and dermatitis-producing nutritional factors, A. F. MORGAN and B. B. COOK (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 2, pp. 281–285*).—Vitamin G (B_2) and lactose are the nutritional factors dealt with in this study to test the relation between absorption disturbances ascribed to these substances and the production of cataract, dermatitis, and growth abnormality. Four groups of rats were fed the usual vitamin-testing type of diet, one formula using cornstarch and the other lactose, to both of which vitamin G (B_2) was added where indicated.

On the cornstarch-vitamin G-low diet, the rats grew very little and developed a severe dermatitis. The constarch-vitamin G-rich dict prevented the development of dermatitis. No cataracts were noted in the animals fed on the cornstarch diet. The vitamin G-low lactose rats showed no skin or fur abnormalities but developed mature bilateral cataracts in from 21 to 35 days. On the lactose-G-rich diet cataracts formed in 85 percent of the rats, but after a long time, 60–84 days.

The authors conclude that "obviously the same deficiency cannot account for the dermatitis and the cataracts here reported. Whatever nutritional failure is caused by the lactose involves no dermatitis and indeed prevents it."

Further studies indicated that lactose, in contrast to cornstarch, either prevented absorption or caused a destruction of the cataract-preventing factor. Two groups of 2 rats on lactose-low G diets were given pure lactoflavine (vitamin G (B_2)) by mouth and by subcutaneous injection, respectively. Both groups developed cataract, but the 2 injected rats made better gains in weight, indicating some intestinal loss of the lactoflavine. Rats fed on a cornstarch-low G diet when fed or injected with pure lactoflavine increased in weight and were cured of dermatitis. This further indicates absorption disturbances caused by lactose.

Differentiation of the antidermatitis factor, A. G. HOGAN and L. R. RICHARDSON (*Science, 83 (1936), No. 2140, pp. 17, 18, fig. 1*).—This contribution from the Missouri Experiment Station is a continuation of studies previously noted (E. S. R., 72, p. 564).

The use of starch or the addition of 100 mg of an alcoholic extract of starch promptly healed the dermatitis which developed in rats on a basal diet supplemented with vitamin B (complex) carrier irradiated with ultraviolet light. Wheat-germ oil showed approximately the same activity,

Mazola and linseed oil were less effective, and coconut oil was entirely ineffective in curing the dermatitis. To show that the dermatitis-preventing factor was not identical with vitamin G, a flavine, a number of rats were given a diet supplemented with tikitiki, which healed the dermatitis but which produced in the rats in from 12 to 16 weeks extensive denuded areas. Wheat-germ oil, 100 mg daily, was ineffective to relieve the denuded condition, but 1 mg organic matter of a flavine preparation produced a new growth of hair in 2 weeks. Flavine preparations given to rats suffering from dermatitis did not cure this condition. The addition of both wheat-germ oil and flavine preparation to the diet produced normal appearance and normal growth.

These results indicated that two factors, an antidermatitis and flavine, are destroyed by ultraviolet irradiations in a vitamin B carrier containing all the members of the vitamin B complex. To determine whether the antidermatitis factor is destroyed by the visible spectrum, a water extract of yeast was exposed through plate glass to a 1,500-w Mazda bulb for 10 hr. at a distance of 10 in. This illuminated preparation prevented and cured dermatitis in rats. Since flavines are labile to the visible spectrum, 1 drop of the flavine preparation added to the diet containing the illuminated preparation produced normal growth.

Dietary production of specific syndrome of deficiency in vitamin B_6, N. HALLIDAY and H. M. EVANS (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 3, pp. 296–299*).—Recent difficulty in inducing in rats on the Sherman-Bourquin diet the specific dermatitis described by Chick et al. (E. S. R., 75, p. 137), György (E. S. R., 75, p. 282), and others suggested the possibility that the wheat extract used as a source of vitamin B_1 was contaminated with the factor responsible for the prevention of dermatitis. When the Sherman-Spohn diet was supplemented by vitamin B_1 crystals, the incidence of dermatitis was greater. Further modification of the diet by extracting the casein with hot 95 percent alcohol produced rough paws and inflamed toes in 35 percent of the rats in 2 weeks.

A preliminary report is given of experiments in which this diet supplemented only with vitamin B_2, or in addition with adsorbed material from alcoholic and aqueous extracts of brewer's yeast or with the adsorbed material from the aqueous extract of hog liver, was fed to rats. At the end of 5 weeks, 30 out of 35 of these rats showed "raw and edematous paws, swollen ears, and sores around the nose and mouth." Some rats died in 4 weeks. The yeast extract filtrate, autoclaved yeast extract filtrate, and the liver extract filtrate prevented this particular dermatitis, and sucrose substituted for the cornstarch in the diet did not produce it. The Sherman-Spohn diet modified by extracting the casein with hot concentrated alcohol and supplemented with B_1 crystals to remove vitamin B_2 more completely readily induced a dermatitis.

The vitamin B [B_1 and B_2 (G)] content of South Dakota lamb (muscle, liver, pancreas, thymus) and vitamin C content of liver, E. PIERSON (*South Dakota Sta. Rpt. 1935, pp. 30, 31*).—This investigation checked the work on vitamin B_1 (E. S. R., 73, p. 274), and determined the vitamin B_2 (G) content in lamb muscle, liver, heart, kidney, and tongue.

Marked progress made in vitamin C research, D. K. TRESSLER (*Farm Res. [New York State Sta.]. 2 (1936), No. 4, pp. 1, 7*).—This paper continues the studies noted previously (E. S. R., 73, p. 727) on the vitamin C content of spinach, peas, rhubarb, tomatoes, snap beans, and cabbage relative to factors which govern the vitamin content. The results showed that spinach, a nonacid vegetable, held at 70° F., lost half of its vitamin content in 3 days and its entire amount in a week. Refrigeration at 35° retarded the loss in spinach to

50 percent in 17 days. On the other hand, tomatoes and rhubarb, both acid vegetables, showed only slight losses of vitamin C at 70°. Variety affected the vitamin content as follows:

Small seeded early varieties of peas, such as Alaska, were richer in vitamin C than the large seeded later varieties, such as Alderman. Early Detroit and Golden Queen tomatoes were 50 percent more potent than other varieties. Georgian and Blue Lake snap beans contained only approximately one-half the amount of vitamin C found in Tendergreen, Kidney Wax, Ideal Market, and Kentucky Wonder. Princess Juliana and King of Denmark spinach were lower in vitamin C content than 10 other varieties grown at the station. On maturity the vitamin C content of peas decreased and that of tomatoes increased. Spinach grown in the autumn had higher vitamin C values than spring spinach. Upland soil produced higher vitamin C values in spinach than muck soil in both spring and autumn.

Cooking studies conducted on snap beans indicated that one-third of the vitamin C dissolved in the cooking water in 20 min., but the actual destruction of the vitamin was less than 10 percent of the total amount present. Blanching, a necessary procedure in preparing peas for freezing, resulted in a loss of vitamin C varying from 10 to 30 percent. Water blanching caused a slightly greater loss than steam blanching.

These results are discussed from the standpoint of their significance in public health.

Milk as a source of vitamin C, C. H. WHITNAH and W. H. RIDDELL (*Science, 83 (1936), No. 2146, p. 162*).—This note from the Kansas Experiment Station reports the protective quantity of fresh raw milk for a guinea pig to be 40 cc per day and of purified vitamin C to be an average of 1 mg per day. A liter of milk, therefore, contained 25 mg of vitamin C. Chemical tests totaling 502 determinations made on the milk of 55 cows representing four major dairy breeds showed the average value to be 25.9±4.3 mg vitamin C per liter. On the basis that the human requirement for vitamin C is from 19 to 27 mg daily, as estimated by Göthlin (E. S. R., 72, p. 886), fresh milk becomes an important source of vitamin C. Proper precautions in handling raw milk and milk pasteurized by the flash method were found to conserve the vitamin C content.

Some effects of experimental diets upon the vitamin C content of certain organs of the guinea pig (Cavia cobaya), I. GILLUM and M. M. KRAMER (*Kans. Acad. Sci. Trans., 38 (1935), pp. 205–207*).—In continuation of the investigation (E. S. R., 72, p. 886) on vitamin C at the Kansas Experiment Station, young guinea pigs were fed the Sherman, LaMer, and Campbell vitamin C-free diet supplemented daily with 5, 10, and 20 cc of orange juice per 300 g of body weight. At 8 weeks of age the animals were killed, and the tissue extracts were titrated for ascorbic acid content with 2,6-dichlorophenolindophenol.

The kidneys and adrenals showed a higher ascorbic acid value per gram of tissue with increased doses of orange juice. The heart remained constant in its ascorbic acid content. The adrenals were shown to be richest in vitamin C content.

The ascorbic acid content of certain organs of chicks raised on vitamin C deficient ration, H. C. HOU (*Science, 82 (1935), No. 2131, p. 423*).—It is noted that in chicks fed on a vitamin C-free diet both with and without ultraviolet irradiation the adrenals, liver, intestines, and intestinal mucus all possess a high content of ascorbic acid, while the pancreas and kidneys contain lesser amounts and the muscle tissue is entirely devoid of this product. Traces were found in the contents of both the small and large intestines, indicating an excretion of ascorbic acid through the intestinal wall.

Further studies pertaining to provitamin D of plant and animal sources, R. M. BETHKE, P. R. RECORD, and O. H. M. WILDER (*Jour. Biol. Chem., 112 (1935), No. 1, pp. 231–238*).—The observation of Waddell, noted previously (E. S. R., 72, p. 888), that the provitamin D of cholesterol and ergosterol was not identical was checked in this investigation at the Ohio Experiment Station on both chicks and rats receiving cod-liver oil, irradiated cholesterol, irradiated ergosterol, and a variety of irradiated animal and plant products as a source of vitamin D.

The data showed that the vitamin D of irradiated cholesterol is more efficacious in preventing rachitic manifestations in the chick than that of irradiated ergosterol or calciferol, which were found to be of the same order of efficiency. The vitamin D of irradiated cholesterol equaled that of cod-liver oil for chicks. The irradiated animal products were more potent antirachitically for chicks than the irradiated plant products when these were fed at equivalent rat units.

These data led to the conclusion that the provitamins of animal and plant products are not identical. There was found to be no difference between the vitamin D of irradiated products from higher plants and that from the lower botanical order.

The effect of organic dietary constituents upon chronic fluorine toxicosis in the rat, P. H. PHILLIPS and E. B. HART (*Jour. Biol. Chem., 109 (1935), No. 2, pp. 657–663, fig. 1*).—In continuation of investigations noted previously (E. S. R., 71, p. 565), carried on at the Wisconsin Experiment Station, the authors gave evidence that fluorine toxicosis was not prevented by a diet low in carbohydrate and high in fat, with the addition of 0.2 percent of sodium fluoride, except to the extent that the high energy value lowered the daily intake of food and consequently the intake of fluorine. The addition of 9 parts each of calcium lactate, potassium and sodium lactate, and lactic acid or glycerol to this diet did not alleviate the toxicity.

A complete inhibition of growth resulted when rats were fed a natural grain diet with the addition of from 78 to 84 mg sodium fluoride per kilogram of body weight. Young rats could not tolerate more than from 6 to 7 mg of fluorine per day. Growth was resumed when fluorine was removed from the diet.

"These data are interpreted to mean that chronic fluorine poisoning involves more than a mechanism responsible for carbohydrate metabolism. The mode of action of F, viewed as a systemic reaction involving enzymatic inhibition, is discussed."

The effect of fluorine upon the phosphatase content of plasma, bones, and teeth of albino rats, M. C. SMITH and E. M. LANTZ (*Jour. Biol. Chem., 112 (1935), No. 1, pp. 303–311*).—In continuation of investigations noted previously (E. S. R., 74, p. 427) carried on at the Arizona Experiment Station, the authors show that plasma phosphatase values of normal control rats on the Sherman diet B decreased with age, reaching a minimum in 70 days, and continued at that value with little change. The plasma phosphatase values of rats on the diet with 0.1 percent sodium fluoride decreased with age, but more slowly, and increased slightly after 70 days. These results are believed to be an indication of stunted bone growth and delayed maturity rather than a specific fluorine effect. The rats receiving 0.025 percent sodium fluoride in the diet, sufficient to cause mottling of teeth but not stunting in bone growth, showed phosphatase values of the same order as that in control animals. The phosphatase content of the incisor teeth was slightly higher in the controls than in the rats receiving 0.1 percent sodium fluoride. It had previously been shown that fluorine inhibited the rate of eruption of these teeth (E. S. R., 72, p. 726). Bone phosphatase values were the same for control and fluorine-fed rats up

to 70 days, after which the values were slightly higher for the latter. Adult rats receiving injections of 0.3 cc of a 2.5 percent sodium fluoride solution showed approximately the same plasma phosphatase values as the controls.

The authors conclude that fluorine does not damage the teeth of rats through its effect on the phosphatase occurring in tooth and bone calcification, and that there was no increase in plasma phosphatase, as had been noted in dairy cows by Phillips (E. S. R., 69, p. 414).

Mottled teeth: An experimental and histologic analysis, I. SCHOUR and M. C. SMITH (*Jour. Amer. Dental Assoc., 22 (1935), No. 5, pp. 796–813, figs. 12*).—Microscopic studies were made on the enamel and dentine of the incisors to determine histologic changes obtained by single or multiple injections of from 0.1 to 0.9 cc of 2.5 percent sodium fluoride solution in 32 rats from 90 to 270 days old. Microscopic examination was also made of the incisors of 16 litter mates used as controls. Detailed findings are given of a number of representative animals showing the response in the enamel and dentine to the fluorine injections. After each injection both the enamel and dentine show a pair of light and dark incremental layers which approximate 32μ for injections given at 48-hr. intervals and 16μ for injections given at 24-hr. intervals. The light layers arising at the time of injection are imperfect in formation and in calcification, and, on the other hand, the dark layers representative of recovery are normal in formation with normal or excessive calcification. These incremental layers occurred when the single dosage was large or with multiple injections of more than 5 at 24-hr. intervals.

The earliest disturbances were observed when animals receiving 0.3 cc of 2.5 percent sodium fluoride were killed 1 hr. after administration. "These changes are recognized in the posterior region of the incisor within the ganoblastic layer in the form of an abnormal character and distribution of globules. In addition, the incremental surface of the organic enamel matrix lacks its normal arrangement and is covered with hemispherical globules that stain deeply with hematoxylin in the animals that were allowed to live from 12 to 24 hr. after the administration." This investigation offered a method of measuring the growth in continuously growing teeth by injections of fluorine. It also gave evidence that the rate of growth of a rat incisor is approximately 16μ in 24 hr. It is believed that fluorosis affected the enamel forming cells directly and not through disturbances in the blood calcium and phosphorus, or in the parathyroids. Twelve microphotographs of sections of incisors are given and explained.

The occurrence of mottled enamel on the temporary teeth, M. C. and H. V. SMITH (*Jour. Amer. Dental Assoc., 22 (1935), No. 5, pp. 814–817, figs. 4*).—The findings in this paper have been essentially noted (E. S. R., 74, p. 427.)

Further studies in mottled enamel, M. C. SMITH, E. M. LANTZ, and H. V. SMITH (*Jour. Amer. Dental Assoc., 22 (1935), No. 5, pp. 817–829, figs. 9*).—In continuation of the studies noted above, a survey showed that in 45 towns or rural districts in Arizona all of the native born children had mottled enamel due to the presence of fluorine in the water supply in concentrations of from 1 to 6 p. p. m. The severity of the mottling varied with the concentration of fluorine in the water. Exceptions were found in people not native born and intermittent users of fluoride-containing water. Since fluorine is widely distributed in minerals occurring in rocks and soils, mottled teeth have been reported in 23 States in the United States and in all the continents except Australia.

Data were included on quantitative studies of the diets of 16 children with mottled teeth and diets of children who were free from this dental defect. The protein and energy content of both diets was adequate, as was calcium, which averaged 1.15 g daily for children with mottled enamel and 1.18 g daily for

those without. A daily vitamin D supplement of cod-liver oil or 250 D viosterol during the school year for 3 yr. between the ages of 6 and 9 yr. did not prevent mottling of the permanent first molars and the central and lateral incisors. These findings were true also in rats fed on rations containing 0.025 percent fluoride and supplemented with cod-liver oil or viosterol.

Experiments were conducted on calcium and phosphorus balances with rats and with dogs fed fluorine in their ration and with children who drank water containing fluorine. The rats fed 0.1 percent fluorine retained 50 percent less calcium and less than 50 percent as much phosphorus as their control litter mates. Fluorine retarded the bone development and rate of eruption of the incisor teeth. The fluorine-fed dogs showed a lowered retention of calcium and phosphorus, although the differences were less striking than in the rats. The girls who lived in districts in which the concentration in drinking water was approximately 4 p. p m. showed no significant or consistent differences in retention of calcium and of phosphorus as compared to control girls living in communities free from the dental defect. The results obtained by adding sodium fluoride, cryolite, calcium fluoride, and barium fluosilicate to the diet of rats to determine the effect on the growth rate of the teeth and on the mortality showed that sodium fluoride was toxic in concentrations of 0.0226 percent of the ration, and that the less soluble compounds had much less toxic effects. Sodium fluoride fed in concentrations of 0.0904 percent of fluorine was fatal, while a daily intake of 10 times as much fluorine in the form of cryolite was not fatal.

Fluorine used in insecticides is discussed from the standpoint of public health.

Mottled enamel in the Salt River Valley and the fluorine content of the water supplies, H. V. and M. C. SMITH and E. O. FOSTER (*Arizona Sta. Tech. Bul. 61 (1936), pp. 372–418, figs. 7*).—In continuation of the series of studies noted above, this investigation included an analysis of the waters for fluorine content in districts of the Salt River Valley and a survey to determine the incidence of mottled enamel among school children in each school district. A map of the townships investigated shows the distribution of fluorine in well water. The territory north and east of Phoenix and that north of the Salt River Mountains had water high in fluorine content, while the territory north and west of Glendale had water generally low in fluorine content. In other areas wells in the same or adjoining sections had either low or high fluorine content in the water. Accompanying tables gave the number and locations of the wells tested in each township.

Analysis of the central water supplies of 11 cities in the Salt River Valley showed the fluorine content to be below the toxic level. Children in these city schools with mottled enamel were users of private wells supplying water with high fluorine content. In the rural section, over one-third of the children had mottled enamel in 17 school districts. In the Squaw Peak and Camelback district, a highly populated area, 57 percent of the children attending school had severely mottled teeth, and an analysis of the water showed it to contain from 12 to 18 p. p. m.

Concentrations of fluorine of from 0 to 0.8 p. p. m. in the water produced no noticeable effect on children's teeth, 0.9 part produced very mild mottled enamel, from 1 to 2 parts produced mild to moderate mottled enamel, from 2 to 3 parts produced moderately severe mottled enamel, from 3 to 6 parts produced severe mottled enamel, and 6 or more p. p. m. produced severe pitting and chipping and deciduous teeth were affected. Water with concentrations of from more than 8 to 10 p. p. m. was found to be unsafe for cooking purposes.

The solution for preventing the occurrence of mottled teeth was avoidance of the use of drinking water containing concentrations of fluorine above 0.9 p. p. m.

Suggested methods for providing safe drinking water were connection with city water mains or hauling city water in bottles, obtaining water from a nearby nontoxic well, deepening or casing existing wells or by drilling new deep wells, and the use of commercially bottled or distilled waters tested as free from fluorine. No satisfactory method of removing fluorine by chemical means from water supplies has been developed.

The fluorine content of some Chinese food materials, E. Reid (*Chin. Jour. Physiol., 10 (1936), No. 2, pp. 259–271, figs. 6*).—Referring to the work of Smith et al. noted above, the author presents data obtained by fluorine analyses of several Chinese food materials, especially those grown in areas where mottled enamel was prevalent or where fluoride deposits occurred. Teas in general, but especially Chinese teas, were found to be high in fluorine content. One Chinese tea grown in a fluorite mining area contained 175.78 mg per 100 g of dry substance. Two percent infusions of several varieties of teas extracted between 81 and 96 percent of the fluorine in the tea in 5 min. Young rats fed rations including tea to the extent of 5 and 10 percent showed white and dark striations in the enamel of the incisors. Analyses of cereals, legumes, roots and tubers, coffees, Chinese wines and citrus fruit juices, and leafy vegetables showed these to be relatively lower in fluorine content. Leafy vegetables in general were higher than seeds and roots. The foods grown in the fluorite mining area gave little evidence that the plants assimilated fluorine from the soil. The exceptions were salted mustard leaves and salted turnip, which may have been due to the fluorine in the salt added to these vegetables. The use of tea as a cause of mottled enamel occurring in China is discussed.

Fluorine in relation to bone and tooth development, F. DeEds (*Jour. Amer. Dental Assoc., 23 (1936), No. 4, pp. 568–574, figs. 5*).—This paper, presented at the 1935 meeting of the California State Dental Association, consists chiefly of a discussion of the literature on the subject, including previous work of the author (E. S. R., 71, p. 726). In addition, a comparison of the bone phosphatase of fluorine-fed rats showed a decreased activity from that of control rats. This effect of fluorine was duplicated in vitro by hydrolysis of sodium glycerophosphate in the presence of sodium fluoride from rat molars.

Relation of certain aciduric bacteria and certain food elements to dental caries, D. C. Lyons (*Jour. Amer. Dental Assoc., 22 (1935), No. 3, pp. 409–421, figs. 6*).—In this investigation a number of experiments were conducted to ascertain the effect of cultures of bacteria obtained from the human decayed tooth and of diets deficient in vitamins on the teeth of rats. Cultures taken from decayed teeth of approximately 500 persons showed predominance of *Lactobacillus acidophilus* for patients between the ages of 1–30 yr., followed by a predominance of flagellated bacilli and streptococci in later years. The gum tissues and impacted food presented a mixture of yeasts, fungi, and bacteria. Cultures of these bacteria were added to sterilized, adequate diets given to rats housed in sterilized cages and individual compartments. After 8 weeks the rats were etherized, examined for dental caries, and cultures made from decayed areas, gum tissues, and impacted foods. Dental decay developed in every instance. Cultures of bacteria recovered from the mouths of these rats were added later to the food of a second group of rats, but dental caries did not develop in all instances. Rats receiving *L. acidophilus* showed no dental decay, but had loosely formed feces, indicating possible contamination of the culture with putrefactive organisms. These results suggested the possibility of the antibiotic relationship of oral flora having an effect upon tooth decay.

The results of feeding to rats diets deficient in vitamins A, B, D, and G, and a miscellaneous diet showed no marked tooth decay.

TEXTILES AND CLOTHING

The influence of various kinds of wool on some of the physical properties of flannel, E. PIERSON (*South Dakota Sta. Rpt. 1935, pp. 31–33*).—This comparative study of wool from five different breeds of sheep used the wool for filling threads in flannel woven expressly for the purpose. Analyses are given for both dyed and undyed material.

The consumer wonders how to judge wool fabrics—tests show only shrinkage related to price, E. L. PHELPS (*Textile World, 84 (1934), No. 12, p. 2228; abs. in Minnesota Sta. Rpt. 1935, p. 46*).—This is an abstract of a paper prepared from material previously noted (E. S. R., 73, p. 732) for the use of the American Society for Testing Materials. The number of woolen fabrics studied, their physical properties, and the significant relationships between price per square yard and the factors measured are given. A criticism of the grab test for measuring tensile strength and some observations on the serigraph test are included.

Silk weighting, M. CHINN and E. L. PHELPS (*Indus. and Engin. Chem., 27 (1935), No. 2, pp. 209–211, figs. 3; abs., in Minnesota Sta. Rpt. 1935, p. 25*).—The first step in the metallic weighting of silk fabrics was studied at the Minnesota Experiment Station, using a series of stannic chloride solutions of increasing concentrations. The optimum concentration for weighting was indicated as 1.2750 sp. gr., with a 10.57 percent maximum retention of weighting on the silk. The retention of weighting by the silk from stannic chloride solutions of lower concentrations was shown to be a positive adsorption reaction, while that with higher concentration was a negative adsorption reaction. The amount of weighting retained was similar for the lowest and highest concentrations of stannic chloride solutions used. The difference in total amounts of weighting retained and the stannic oxide found in the samples was assumed to be due to the effect of a new equilibrium reached in the rinsing bath in combination with positive and negative adsorption. Weighted silk adsorbs approximately the same amount of moisture (8.6 percent) under standard temperature and humidity regardless of the amount of weighting present.

A study of clothing costs for a freshman girl, H. K. ROBSON (*Jour. Home Econ., 28 (1936), No. 1, pp. 30, 31*).—The clothing costs presented for 44 freshman college girls show that an average of $108.93, with a range of from $6.93 to $564.74, was spent for new fall clothing, an average of $51.25 for additional clothing during the first semester, and an average of $9.48 for upkeep and personal grooming. Cost figures were also presented for certain clothing items.

HOME MANAGEMENT AND EQUIPMENT

[Standard of rural living in Montana] (*Montana Sta. Rpt. 1934, pp. 42, 43*).—Summaries are included of studies on the cost of a satisfactory standard of rural living, on contributions from the farm to family living, on the improvement of the quality of the food produced on the farm for family use, and on the preservation of the food produced on the farm for family use.

Electric refrigeration and air conditioning (*Lubrication, 22 (1936), No. 6, pp. 61–72, figs. 19*).—This is a technical discussion of different types of home refrigeration.

MISCELLANEOUS

Laws applicable to the United States Department of Agriculture, 1935, compiled by J. P. WENCHEL and M. E. MOORE (*U. S. Dept. Agr., 1936, pp. XXII+750*).—This supersedes the work previously noted (E. S. R., 53, p. 299), embracing acts and provisions of a permanent character in force on September 6, 1935.

Annual Report [of Florida Station], 1935, W. NEWELL ET AL. (*Florida Sta. Rpt. 1935, pp. 152+VIII, figs. 12*).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue. Meteorological observations in the Everglades (pp. 102–105) and at the North Florida Substation at Quincy (p. 133) are also included.

Science aids Idaho farmers: The Annual Report of the [Idaho] Agricultural Experiment Station for the year ending December 31, 1935 [E. J. IDDINGS ET AL.] (*Idaho Sta. Bul. 220 (1936), pp. 62, figs. 17*).—The experimental work not previously reported is for the most part noted elsewhere in this issue.

Forty-eighth Annual Report of the [Michigan Station], 1935, V. R. GARDNER ET AL. (*Michigan Sta. Rpt. 1935, pp. 151–239, figs. 3*).—The experimental work not previously reported is for the most part noted elsewhere in this issue. Analyses of vinegar (pp. 203, 204), bacterial studies on the quality of swimming-pool waters (pp. 204–207) and cost studies for beans, potatoes, and beef production (pp. 222, 223) are also included.

Forty-second Annual Report [of Minnesota Station], 1935, A. Boss (*Minnesota Sta. Rpt. 1935, pp. 89*).—In addition to data noted previously or elsewhere in this issue, this report contains abstracts of the following: Physiology of the Adaptation of Plants to Low Temperature, by R. B Harvey (p. 20); Power From the Prairie, by C. H. Bailey (p. 26); Two New Bird Ceratophylli From Minnesota (Insecta: Siphonaptera), by C. Y. Liu (p. 41); Making Hay With the Windrow Baler, by A. J. Schwantes (p. 45); The Economics of Long-Lived Farm Structures, by W. Boss (p. 46); Shelterbelt Planting Revealed in Early Minnesota Forestry, by H. Schmitz (p. 47); The Vitamins: A Discussion of Some Aspects of Past and Present Knowledge, by L. S. Palmer (p 47); and Edible Fruits From Minnesota Wild and Cultivated Plants, by L. Sando (p. 47).

Reshaping Montana's agriculture: The Forty-first Annual Report of the Montana Agricultural Experiment Station, [1934], F. B. LINFIELD (*Montana Sta. Rpt. 1934, pp. 83, figs. 14*).—In this report the current agricultural situation is discussed, and the opportunities and responsibilities of the station are outlined. A meteorological report for 1934 is included (pp. 77–80). The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-sixth Annual Report of the New Jersey State Agricultural Experiment Station and the Forty-eighth Annual Report of the New Jersey Agricultural College Experiment Station for the year ending June 30, 1935, J. G. LIPMAN (*New Jersey Stas. Rpt. 1935, pp. XXIII+122, fig. 1*).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

Annual Report of the South Dakota Agricultural Experiment Station, [1935], J. W. WILSON ET AL. (*South Dakota Sta. Rpt. 1935, pp. 48*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

NOTES

Louisiana University and Station.—Dr. W. R. Dodson, until 1928 dean of the College of Agriculture and director of the station and subsequently in charge of animal husbandry work at the U. S. D. A. Iberia Livestock Experiment Farm, has returned to the department of agronomy for teaching and extension work. The honorary D. Sc. degree was conferred upon him by the university on August 6 in recognition of his long service "to the youth of the State of Louisiana as a teacher and leader in agriculture, as an organizer of forces for the development of better agricultural conditions in the South, and for launching the movement that resulted in the establishment of the . . . university on its present site."

Missouri University.—The College of Agriculture has enrolled 720 students in agriculture and home economics. This is the largest number in its history and more than double that of 3 years ago.

Cornell University and Station.—Dr. Oskar A. Johannsen has been appointed head of the department of entomology vice Dr. J. G. Needham, who retired July 1. H. C. Troy, professor of dairy industry, also retired July 1. Dr. Vernon Frampton has been appointed assistant professor of plant pathology for work on the chemical nature and control of virus diseases. Glenn W. Hedlund, extension instructor in marketing, has been granted a year's leave of absence to teach farm management and cooperative marketing in Nanking, China.

New York State Station.—One of the very few successful attempts to hybridize pumpkin and squash has been made by the station, about a dozen fruits being obtained from more than 100 cross-pollinations. These new plant forms have thrown considerable light on the botanical relationships of squashes and pumpkins, and are also of interest to the vegetable grower since the new varieties seem to be either immune or highly resistant to squash mosaic.

Clemson College and South Carolina Station.—Dr. H. P. Cooper, head of the department of agronomy, has been appointed director of the station, effective July 1.

Joseph N. Harper, head of the department of agriculture in the college and director of the station from 1905 to 1917 and widely known throughout the South, died in Atlanta, Ga., on July 1 at the age of 62 years. Born in Mississippi and graduated from the Mississippi College in 1895, he was appointed agronomist in the Kentucky Station in 1898 and received the M. S. A. degree from the University of Kentucky in 1906. Since leaving South Carolina he had been engaged in commercial work for various fertilizer interests.

Wisconsin Station.—An extensive program of research on potatoes has been begun with the objective of better quality. Potatoes from many parts of the United States, Central and South America, and Europe are to be assembled for breeding work to be carried on near Port Wing on the shores of Lake Superior. The program will be conducted under the supervision of a committee representing breeding, disease resistance, and adaptation studies and will include physiological, chemical, soils, and insect investigations. The field work, as well as greenhouse trials in Madison, will be in charge of Dr. G. H. Rieman, who has been head of plant breeding work for a large vegetable seed producing organization.

EXPERIMENT STATION RECORD

VOL. 75 DECEMBER 1936 No. 6

DR. TRUE'S HISTORY OF AGRICULTURAL EXPERIMENTATION AND RESEARCH

The invaluable trilogy of monographs of agricultural education, extension, and research, preparation of which was begun by the Federal Department of Agriculture about a decade ago, will soon be completed by the issuance of the third and final member of the series. This is entitled A History of Agricultural Experimentation and Research in the United States, 1620–1925, and will appear as Publication 251 in the Miscellaneous Series of the Department. Like its predecessors it is from the pen of Dr. A. C. True, the manuscript having reached substantial completion upon his death in 1929.

The primary purpose of the series—the presentation of a comprehensive summary of factual information—has been consistently adhered to, so it is not surprising that the publication extends over some 300 pages and contains a wealth of detail. As in the preceding monographs, considerable space has been given to examples of the work of private individuals and organizations in laying the foundations for the establishment of public agencies for agricultural research. However, after the passage of the Hatch Act for the maintenance of State experiment stations and the elevation of the Federal Department of Agriculture to Cabinet rank, the work of these agencies spread out so broadly that in the recapitulation of the past half century a more extensive basis of treatment was found necessary, and little has been attempted beyond describing the organization and equipment of their research and its general character and breadth.

Following a discussion of beginnings in the days of the colonies and early statehood, there has been substituted in lieu of a strict chronology of all agricultural research more or less of a differentiation of that conducted directly by the Federal Government and that carried on by the State experiment stations and other agencies. Sections are set up taking in turn the work of the Federal Government under the Patent Office and by the Department of Agriculture prior to 1889; the movement in the States toward the establishment of

agricultural research institutions, 1840–75; State agricultural experiment stations without Federal aid, 1875–88; agricultural experiments in States not having experiment stations, 1875–88; the Hatch Act and the stations thereunder, 1888–1905, and the movement for increased aid culminating in the Adams Act, 1902–6; the Department from 1889 to 1897; development of research in agricultural production, 1897–1913, by the Department and the stations; the development of research in agricultural economics and sociology, 1913–21; agricultural experiment stations as affected by the Smith-Lever Extension Act and the World War, 1914–20; and agricultural research during the agricultural depression, 1921–25, by the Department and the stations. The history closes with the enactment of the Purnell Act of 1925.

This method of treatment has the advantage of concentrating attention on significant movements with a minimum of dilution by nonrelevant occurrences. It has the corresponding disadvantage of separating many events of contemporaneous date and of creating some duplications of treatments as well as some uncertainty as to where specific happenings have been discussed. These drawbacks are overcome to some extent by frequent cross-references and a comprehensive index.

Needless to say the material included has been selected, assembled, and evaluated with meticulous care, and from the point of view of its preservation in available form this alone would constitute an achievement abundantly worth-while. The monograph, however, is much more than a compendium of data. Great pains have been taken to discover and analyze causes and trends and to present the underlying philosophy of the movement as completely as possible within the space limitations. This is particularly the case as regards the evolution of the experiment stations. For this task Dr. True was, of course, exceptionally well fitted by temperament and experience.

The appearance of this authoritative monograph will be welcomed by all who are interested in the growth of American research institutions for agriculture. It has been long needed and will fill a unique place as a work of reference and orientation, and should be especially useful as a repository of source material. Perhaps it may serve as a starting point and activator for a more popular and dramatic treatment under other auspices of some of the myriad individual matters with which it has to deal.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

The proteins of the cowpea (Vigna sinensis), W. H. ADOLPH and H. C. CHIANG (*Chin. Jour. Physiol., 9 (1935), No. 4, pp. 347–353*).—The pale reddish seeds of *V. sinensis sesquipedalis* were finely ground and analyzed by the Van Slyke method for the purpose of isolating previously unidentified protein fractions.

One kg of the cowpea meal was treated with 5 l of water, stirred for 3 hr., and allowed to stand overnight in a cold place. The liquid was separated by decantation and with a filter press, treated with ammonium sulfate to 0.7 saturation, allowed to stand overnight, and filtered. The precipitate was redissolved in water, dialyzed, filtered from traces of globulin, and the filtrate heated to 66° [C.] on a water bath. This process yielded 17 g of a coagulated protein which was termed an albumin. The filtrate obtained by this procedure was diluted with 3 volumes of water and heated to 73°. The coagulated protein was termed globulin B and yielded 11 g. The filtrate was again heated to 90° and the coagulum was termed globulin C. The yield was 2.5 g. All these fractions were purified by washing and drying in the usual way.

The residue from the water-extracted cowpea meal was treated with 5 l of 8 percent sodium chloride, and vignin (globulin A) was precipitated from the filtrate by dilution with 7 volumes of water. The yield was 60 g. The residue left by this procedure was treated with 5 l of 0.2 percent sodium hydroxide and left overnight. The liquid was separated and treated with sodium chloride to give a concentration of 5 percent with respect to this salt and made acid to litmus and neutral to congo red by adding hydrochloric acid. The resulting precipitate was termed a glutelin and the yield was 34 g of the purified protein.

Analysis was made of the five protein fractions to determine the carbon, hydrogen, oxygen, and sulfur content. Estimates of the relative percentages were vignin (globulin A) 45 percent, glutelin 25, albumin 15, globulin B 10, and globulin C 5 percent. The glutelin and albumin were believed previously unidentified. Amino nitrogen analysis on four of the protein fractions showed the glutelin to be high in cystine and the globulins and albumin to be high in lysine.

Effect of different buffers and type of substrate on the diastasis of wheat starch, C. E. MANGELS and J. J. MARTIN, JR. (*Cereal Chem., 12 (1935), No. 5, pp. 256–268, figs. 4*).—This investigation, made at the North Dakota Experiment Station, determined the effect of three buffer solutions, McIlvaine's citric acid-sodium phosphate buffer (pH range 2.2–8.0), Walpole's acetate buffer (pH range 3.6–5.6), and Sørenson's phosphate buffer (pH range 5.3–8.0), on the diastatic activity of wheat flour and pure raw starch.

Wheat flour produced more maltose in 60 min. with Sørenson's phosphate buffer than with the other two buffers. The optimum point of diastatic activity for McIlvaine's buffer was pH 5.0, for Sørenson's buffer pH 5.2–5.6, while Walpole's buffer did not show an optimum point for wheat flour. Pure raw

starch substrate, with malt and takadiastase as a source of enzyme, shifted the optimum point to the alkaline side, McIlvaine's buffer showing a greater shift than Sørenson's phosphate buffer. Cooked starch substrate with malt and takadiastase as the source of the enzyme tended to shift the optimum point to the acid side as compared with raw starch. Wheat flour and pure raw starch as substrates formed practically the same amounts of maltose. On the other hand from 60 to 70 percent of cooked starch with malt diastase was converted into maltose, while only 2 percent of raw starch was converted by the same quantity of the enzyme. This difference in sugar formation was so large that results with cooked starch were of no value in predicting the diastatic susceptibility of raw starch. For the determination of diastatic activity of wheat flour doughs, it was found important to have the starch substrate similar to the natural starch of the wheat flour.

Hemicellulose constituents in alfalfa roots, B. A. BURKHART (*Plant Physiol., 11 (1936), No. 2, pp. 421–428*).—In this study at the Wisconsin Experiment Station, the hemicelluloses of the root phloem and xylem tissues soluble in 5 percent NaOH were isolated, purified, and analyzed, falling into two main fractions, an acid-insoluble one (hemicellulose A) and an acid-soluble, alcohol-insoluble one (hemicellulose B). Using Fehling's solution, hemicelluloses A–2 and B–2 were also obtained. The chief sugars in all fractions were *d*-xylose and *d*-glucose, but some *d*-glucuronic was also present. The most significant variation between the phloem and xylem hemicelluloses was the higher xylose content in the latter. The content of *d*-glucuronic acid was highest in the phloem hemicellulose.

Colloid chemistry of cellulosic materials, A. J. STAMM (*U. S. Dept. Agr., Misc. Pub. 240 (1936), pp. 91*).—The author states that he has not undertaken a review of all researches on the colloidal properties of cellulosic materials and that the appended bibliography (280 citations) is "far from complete." He "has attempted more to tie together salient findings regarding the more important colloidal properties of the cellulosic materials. . . .

"The colloid chemistry of cellulosic materials is now at the stages of transition from a qualitative to a quantitative science. Further researches directed toward the determination of the quantitative interrelationship of the various colloidal properties will make possible a more intimate understanding of the physical nature of cellulose which, in turn, will undoubtedly strengthen its claim to being the world's most important organic raw material."

Microscopical phenomena in emulsifying and breaking cresoap emulsions of petroleum oils, P. A. YOUNG (*Amer. Micros. Soc. Trans., 55 (1936), No. 2, pp. 260–274, pl. 1, figs. 5*).—Microscopic studies conducted at the Montana Experiment Station resulted in the identification of the structures and explained the formation of cresoap emulsions of petroleum oils in water. When a cresoap-miscible oil touched water, emulsification quickly occurred, mainly by the following methods: "Continuous phase water and oil formed a partial interface. Jets of oil flowed through temporary holes in this interface and dispersed myriads of oil globules in the water. Oppositely rotating pairs of horizontal currents in the oil and water beside the interface, and vertically rolling cylindrical currents in the oil beside the interface, apparently drove masses of liquids through the interface and helped to disperse spheres of oil and water. The interface curved and made knobs many of which abstricted spheres of emulsion into the continuous phases.

"When petroleum oil containing Oil Red O and cresoap touched water containing methylene blue, the methylene blue mixed with the cresoap to form dark blue spheres as a separate phase dispersed in oil and water. The other

phenomena of emulsification were like those in unstained oil and water. Six stable phases and four unstable phases were described in emulsions with oil, cresoap water, and methylene blue."

Besides simple oil globules, spray emulsions contained dispersed globules of emulsions. The phenomenon of positive adsorption of solutes at interfaces was demonstrated visibly with cresoap. Potassium bromide and sodium chloride each caused rapid coalescence of oil globules in emulsions. Also, dextrose and sucrose caused slow breaking of emulsions in test tubes.

Studies on biological oxidations.—V, Copper and hemochromogens as catalysts for the oxidation of ascorbic acid. The mechanism of the oxidation, E. S. G. BARRON, R. H. DEMEIO, and F. KLEMPERER (*Jour. Biol. Chem., 112 (1936), No. 2, pp. 625–640, figs. 5*).—In this study on the oxidation of ascorbic acid, extreme care was taken not to contaminate solutions with copper by chemicals and apparatus.

Ascorbic acid was oxidized by a current of air at 25°C. when the experiment was performed at a pH value of 7.60 or above. As the rate of alkalinity increased from pH 8 to pH 10 the rate of oxidation increased. The oxidation proceeded until 1 atom of oxygen had been used for each molecule of ascorbic acid, resulting in oxalic acid and *l*-threonic acid.

Copper, as $CuCl_2$, in concentrations of 46 mg per liter had a catalytic action on the oxidation process when performed in alkaline, acid, and neutral solutions. The maximum rate of reaction with copper as a catalyst occurred at pH 6.95; below that pH the rate of oxidation slowed rapidly. Manganese, iron, nickel, cobalt, and calcium and also hemin had no catalytic effect on the oxidation process. Three hemochromogens, nicotine, pyridine, and pylocarpine, were found to act as catalysts.

Oxidized ascorbic acid was completely reduced by H_2S up to pH 5.0, and above this pH to pH 7.6 it was partially reduced. No reduction was detected using hydrogen in the presence of colloidal palladium.

A change of 10° in temperature had little effect on the oxidation process. The temperature coefficient for the oxidation of ascorbic acid, using copper in the ratio of 1 part $CuCl_2$: 100 parts of ascorbic acid as catalyst at from 27° to 37° at pH 3.17, was found to be 1.65.

The electromotive measurements of the hemochromogens (unpublished work) showed that as the oxidation reduction potentials became more positive the catalytic power increased.

The procedure and mechanism of the oxidation of ascorbic acid by atmospheric oxygen in the presence of catalytic agents are discussed.

Ascorbic acid in the urine [trans. title], F. WIDENBAUER (*Klin. Wchnschr., 15 (1936), No. 3, pp. 94, 95*).—Determining the ascorbic acid content of 8 urines, the author obtained lower values with the indophenol method of Harris and Ray than those obtained with the iodine titration method and, therefore, concluded that the indophenol method was more but not absolutely specific in its reaction. The relative accuracy of the two methods was further determined by titrating solutions of pigments obtained from the urine by absorption with animal charcoal and extracted by successive treatments with ammoniacal alcohol and absolute alcohol. Water solutions of these native pigments, dark brown in color, strongly reduced indophenol and iodine solutions. Preparations of urochrome A and B were made and rendered free from ascorbic acid. Water solutions of these pigments yielded an average value of 0.104 mg ascorbic acid with the indophenol method and 0.352 mg with the iodine method. These results indicated that for a daily excretion of 1,000 cc of urine reducing values of 4.16 and 14.08 mg calculated as ascorbic acid could be obtained without the presence of ascorbic acid in the urine.

To further examine methods for vitamin C determination in the urine, the test dose method of Harris and Ray (E. S. R., 73, p. 427), which determined the state of vitamin C nutrition, was applied to two infants. One receiving 1,000 mg of ascorbic acid gave a maximum response of 35.15 mg ascorbic acid excreted in the urine and the other receiving 150 mg excreted 44.5 mg. Since the amounts excreted by both infants before and after the test doses were given differed but little, it must be concluded that the vitamin C economy was quite different for the two children, indicating the importance of using the test dose.

The demonstration of vitamin C (ascorbic acid) in the urine [trans. title], A. EMMERIE and M. VAN EEKELEN (*Klin. Wchnschr., 15 (1936), No. 10, p. 348*).—This note corrects an error in the paper by Ammon and Hinsberg noted above in which lead acetate was used instead of mercuric acetate in the modified 2,6-dichlorophenolindophenol procedure previously described by the authors (E. S. R., 73, p. 583). Lead acetate was shown to precipitate ascorbic acid and, therefore, could not be used. In referring to the paper by Widenbauer noted above, the authors stated that the indophenol method was entirely satisfactory when reducing substances other than ascorbic acid and pigments were precipitated with mercuric acetate and when the partially oxidized ascorbic acid was reduced with H_2S before titrating with the dye. The time interval must be short, about 5 min., between mercuric acetate treatment and reduction with H_2S, so that all the ascorbic acid is in the reduced form.

The isolation from wheat germ oil of an alcohol, α-tocopherol, having the properties of vitamin E, H. M. EVANS and O. H. and G. A. EMERSON (*Jour. Biol. Chem., 113 (1936), No. 1, pp. 319–332, figs. 2*).—In this study from the University of California, an oily alcohol having the properties of vitamin E was isolated from the nonsaponifiable matter of wheat-germ oil with the use of cyanic acid. The name proposed for the alcohol was α-tocopherol from the roots "tokos=childbirth; phero=to bear; -ol indicating an alcohol." It has a melting point of from 158° to 160° C.; a characteristic absorption band at 2,980 a. u., $E^{1\ \text{percent}}_{1\ \text{cm}} = 90$ *ca;* and an analysis of two derivatives, urethane and allophanate, indicated a provisional formula of $C_{29}H_{50}O_2$. Two other allophanates isomeric with α-tocopherol were also obtained from the wheat-germ oil. One allophanate with a melting point of 250° had no vitamin E potency and the other with a melting point of 138° had some vitamin E potency. Single doses of 1 mg of α-tocopherol produced litters of rats sporadically and 3 mg produced litters quite regularly.

Adaptation of the micro-Kjeldahl method for the determination of nitrogen in plant tissues, N. W. STUART (*Plant Physiol., 11 (1936), No. 1, pp. 173–179*).—In this contribution by the Maryland Experiment Station, the Pregl micro-Kjeldahl method used in organic chemistry laboratories for determination of nitrogen was applied to the determination of total organic nitrogen in plant tissues. Micromethods are proposed for the estimation of nonprotein, basic, and amide nitrogen in plant extracts. It is concluded that micromethods are rapid, economical, and as accurate as macromethods for determinations of total organic nitrogen in plant tissues, and of nonprotein, basic, and amide nitrogen in plant extracts.

Physiological investigations of change in the membrane materials of the higher plants.—I, Descriptions of methods for analyses of the principal membrane substances and a critical study of the method of quantitative comparison [trans. title], T. FUJITA (*Bul. Sci. Fakult. Terkult., Kjûsu Imp. Univ., Fukuoka, Japan, 6 (1935), No. 4, pp. 387–403; Ger. abs., pp. 402, 403*).—Including the Köketsu pulverizing method (E. S. R., 61 p. 627), the author presents and describes procedures for the analysis of such membrane substances as pectin, cellulose, hemicellulose, and lignin, and for comparisons be-

tween old and young leaves or between different plant organs as to their content in these substances.

Chlorophyllometry, L. H. RODDIS (*Plant Physiol., 11 (1936), No. 1, pp. 211, 212*).—This is an application of methods of hemoglobinometry to chlorophyll estimation. Relative chlorophyll determination is made by colorimeter comparisons of fresh alcoholic extractions from the leaf.

The fluorometric estimation of lactoflavin, G. C. SUPPLEE, S. ANSBACHER, G. E. FLANIGAN, and Z. M. HANFORD (*Jour. Dairy Sci., 19 (1936), No. 3, pp. 215–220, pls. 2*).—This contribution describes a simple method for quantitatively estimating the lactoflavin content of solutions based on its fluorescent properties in "black light". This method requires only standard lactoflavin solutions and an ultraviolet light generator with a suitable filter, and was found to be accurate to 0.1γ of lactoflavin, while concentrations as low as 0.05γ per milliliter could be detected. It is applicable not only to solutions of pure lactoflavin but also to concentrates containing relatively large amounts of impurities, provided the impurities do not interfere with the fluorescent color.

Modifications of the bipyridine method for available iron, G. O. KOHLER, C. A. ELVEHJEM, *and* E. B. HART (*Jour. Biol. Chem., 113 (1936), No. 1, pp. 49–53*).—This paper from the Wisconsin Experiment Station presented modifications of the α,α'-bipyridine method of Hill (E. S. R., 64, p. 712) for pigmented plant tissues and for fresh animal tissues.

A plant tissue sample with an approximate iron content of 0.01 mg was treated with acetic acid, α,α'-bipyridine in 10 percent acetic acid and hydroquinone, allowed to stand until maximum color had developed, treated with a lead acetate solution, allowed to stand overnight, then centrifuged, and the color compared with that of the standard. Fresh tissues gave better results than dried samples. For very bulky materials better results were obtained when the reagents were doubled.

For fresh animal tissues samples were treated with trichloroacetic acid, hydroquinone, and α,α'-bipyridine in 10 percent acetic acid, allowed to stand overnight, then treated with alcohol, and continued with the procedure used for the plant tissues.

For fresh tissues the water content was determined and was taken into account in calculating the available iron. Determination of the pH of the tissue is advised to make certain that the range is between 2.5 and 5 before comparing colors. Results are given of the determinations of available iron of 14 food materials, some in duplicate.

Studies on aluminum.—I, A critical study of quantitative colorimetric methods for aluminum on biological material, D. F. EVELETH and V. C. MYERS (*Jour. Biol. Chem., 113 (1936), No. 2, pp. 449–465*).—In this investigation colorimetric methods for the determination of aluminum described by Underhill and Peterman (E. S. R., 62, p. 503) and Myers, Mull, and Morrison (E. S. R., 60, p. 312) were applied to biological tissues to determine their relative accuracy for quantitative aluminum studies. The procedure developed for the preparation of tissues used dry ashing in preference to wet ashing in view of the formation of an insoluble precipitate in the acid which cannot be removed from the Kjeldahl flask. Wet ashing also requires the use of nitric and sulfuric acids, which in quantities used for a 50-g sample of tissue contain demonstrable amounts of aluminum. To remove interfering substances, aluminum and iron were quantitatively precipitated as phosphates to remove other metallic salts and then separated by means of sodium hydroxide, ammonium thiocyanate, or cupferron. The three methods for separating the aluminum were found to be equally satisfactory. The results indicated that aurin, used by

Myers et al., was the most specific and satisfactory reagent for the colorimetric determinations. Aurin, alizarin, and 8-hydroxyquinoline yielded identical results when the tissue digests were free from all known interfering substances. 1,2,5,8-hydroxyanthraquinone was found a sensitive reagent for qualitative determinations for aluminum.

On the detection of added water in milk, B. DAVIES (*Jour. Dairy Res. [London], 6 (1935), No. 1, pp. 56–71, pl. 1, figs. 5*).—The author proposes a formula combining the refractive index, the electrical conductivity, and the rotation of the plane of polarization of milk by which it is possible to determine quantitatively the degree of water adulteration in milk.

The determination of ascorbic acid in urine with phospho-18-tungstic acid, G. MEDES (*Biochem. Jour., 29 (1935), No. 10, pp. 2251–2255, figs. 2*).—A new method for the determination of vitamin C in the urine employed Folin's phospho-18-tungstic acid reagent (E. S. R., 73, p. 149), which produced a blue color with ascorbic acid in about 3 min. at room temperatures of 26°±4° C. The reaction was carried out in acid solution pH 5 to prevent interference of all reducing substances except thiol compounds, and the action of these compounds was prevented by the addition of formaldehyde. The urine was titrated against 1, 2, and 4 cc of standard 0.001 M ascorbic acid solution. The calculation was made by the formula $0.001 \times \frac{N}{n} \times \frac{20}{R} \times 0.1 = g$ mols ascorbic acid per 100 cc of urine, where N represented the cubic centimeters of the standard, n the cubic centimeters of urine, and R the reading of the colorimeter with standard set at 20.

A method for the preservation of urine for several hours is described. Freshly voided urine is acidified with acetic acid and saturated with hydrogen sulfide. When ready for the ascorbic acid determination, carbon dioxide or nitrogen is bubbled through to remove the sulfide.

Observations on methods for determining vitamin C in the urine [trans. title], R. AMMON and K. HINSBERG (*Klin. Wchnschr., 15 (1936), No. 3, pp. 85–88*).—This study analyzed three titration methods for determining ascorbic acid in the urine for their respective accuracies in giving exact quantitative values. The iodine titration method yielded high values due to the presence of reducing substances, cysteine and glutathiones, which reduced iodine solutions in acid medium. The use of potassium iodide to prevent the reduction of the iodine solution by cysteine lowered the iodine value but left other interfering substances in the urine, and there was some question whether cysteine completely lost its reducing property by this procedure. The difficulty with the 2,6-dichlorophenolindophenol titration method (Tillmans'), was interference due to natural pigments in the urine, an indefinite end point with certain solutions, the presence of other reducing substances, and the fact that the unknown solution was not titrated against a known solution. These factors tended to yield values too high.

The methylene blue method of Martini and Bonsignore (E. S. R., 73, p. 746) compared the unknown solution with a control solution of known quantities of methylene blue. Reducing substances such as cysteine and glutathione did not interfere with this method. When it was applied to urines, the control solution was pigmented with a weak solution of bromothymol blue to the same degree as the urine. This method has certain difficulties such as an indistinct end point in very dark colored urines and the production of reducing substances through a long exposure to the 500–1,000 w lamp used for this method. Determinations of milligrams percent of ascorbic acid in the urine by the iodine, potassium iodide-iodine, and indophenol methods yielded values considerably higher than the methylene blue method. The preparation Detoxin, containing no

appreciable amounts of vitamin C. gave a value of 16.95 mg percent with iodine, 10.90 with potassium iodide-iodine, 9.52 with indophenol, and 0.16 with the methylene blue method. For 100 g placenta the values averaged 25.2 mg percent of ascorbic acid for the iodine method, 14.11 for the potassium iodide-iodine, 8.84 for the indophenol, and 1.30 for the methylene blue.

The modification of the indophenol method described by Emmerie and Van Eekelen (E. S. R., 73, p. 583) and the method of Tauber and Kleiner (E. S. R., 73, p. 885) were discussed briefly for their accuracy. It was noted that ascorbic acid in the urine is unstable and that, therefore, determinations by all the methods should be made on freshly excreted urine. Of the three methods, only the methylene blue method was considered to yield values approximating that of true ascorbic acid content in urine and placenta, but it also was not considered specific and quantitative.

A method to determine small amounts of citric acid in biological material, G. W. PUCHER, C. C. SHERMAN, and H. B. VICKERY (*Jour. Biol. Chem., 113 (1936), No. 1, pp. 235–245*).—In this contribution from the Connecticut [New Haven] Experiment Station, a method is described for determining from 0.1 to 1 mg of citric acid with an accuracy of ±5 percent. The procedure consists of oxidizing citric acid by potassium permanganate in the presence of bromine to form pentabromoacetone. This substance is extracted with petroleum ether, treated with aqueous sodium sulfide, and stabilized with the addition of pyridine. By means of a Pulfrich spectrophotometer the intensity of the color of the solution is determined, and the quantity of citric acid originally present is estimated from the calibration curve of the instrument.

Application of this method was made on blood, urine, feces, and animal and plant tissues for their respective citric acid content.

Studies on the utilization of soybeans (*Indiana Sta. Rpt. 1935, pp. 55, 56*).—Data are given as to the conformity of iodine and potassium iodide solutions used for color evaluations of soybean oil with Beer's law and methods for the removal of phosphatides from crude soybean oil.

Manufacture of table sirups from sugarcane (*Puerto Rico Sta. Rpt. 1935, p. 26*).—Data are reported as to the desirability of blending several varieties for superior flavor and on the prevention of crystallization by the addition of invertase.

Production of sauer rüben, H. E. GORESLINE and L. H. JAMES (*U. S. Dept. Agr. Circ. 389 (1936), pp. 10, figs. 4*).—Sauer rüben was made from 17 varieties of turnips and 6 other kinds of root vegetables. The Purple Top Strap Leaf turnip produced a product graded as excellent. Six other varieties were graded as good.

A good product was made from both spring and fall turnips, although better results were usually obtained from the fall crop. Turnips ranging from 2.5 to 3.5 in. in diameter produced a sauer rüben of flavor and texture superior to that from turnips smaller or larger in size. Turnips with a total sugar content of from 3.25 to 5.31 percent produced good sauer rüben, although the higher sugar content was more desirable as it produced a higher acidity. Peeling the turnips removed some of the sugar and resulted in a product which had a very mild flavor but low acidity and inferior keeping quality. Shredded turnips produced a sauer rüben of superior quality, the texture of which resembled that of sauerkraut more closely than did that yielded by either ground or sliced turnips. A more tasty sauer rüben was obtained when 2.2 percent of salt was used than with the 2.5 percent of salt ordinarily used in making sauerkraut.

"Sauer rüben can be fermented and kept a long time by packing in such a way as to exclude air from the product. Closed glass containers were more

effective in this than either open jars covered with mineral oil or jars left exposed to the air. Sauer rüben can be fermented in closed jars and stored for considerable periods at temperatures ranging from 42° to 80° F. without sterilizing. Exposure of sauer rüben to the air resulted in a darkening of the product and eventual spoilage. Sauer rüben can be canned in tins by using a 2.5-min. exhaust and a 7-min. cook in flowing steam. This method gives a tender product and insures preservation of the material."

AGRICULTURAL METEOROLOGY

Climatic features in relation to agriculture (*Puerto Rico Sta. Rpt. 1935, pp. 4–12, figs. 5*).—Climatic features of Puerto Rico are shown to be an important agricultural asset because of 12 mo. of temperature favorable to plant growth, freedom from frost, and abundant rainfall, and for other reasons, affording opportunity for growth of winter crops and for year-round experimental work. It is necessary, however, to safeguard against hurricane damage by selecting crops less subject to such damage and against soil erosion due to heavy and sometimes torrential rainfall. Amount and distribution of rainfall in the island are shown graphically in a series of charts.

The influence of the sun on human affairs, H. T. Stetson (*Sci. Mo., 43 (1936), No. 1, pp. 14–22*).—From his study the author concludes among other things that "the effect of sunspots on biological behavior appears to have been established beyond contention through the growth of trees whose ring patterns have been definitely shown by Douglass (E. S. R., 60, p. 417) to show the sunspot cycle through the centuries. . . . The question of the effect of the solar cycle on the weather is highly complex, but sufficient evidence seems to have been presented to give a basis for believing that storminess on the earth migrates through definite cycles, which follow in general the cycle of solar activity."

The influence of solar variability on weather, C. G. Abbot (*Sci. Mo., 43 (1936), No. 2, pp. 108–121, figs. 14*).—The author presents evidence from variation in solar radiation which convinces him that such variation is an important weather factor hitherto generally unrecognized.

Method of forecasting rainfall in behalf of the time of sowing tobacco [trans. title], C. Coolhaas (*Proefsta. Vorstenland. Tabak [Dutch East Indies], Meded. 83 (1936), pp. [1]+17; Eng. abs., pp. 16, 17*).—The author proposes an improvement of the Tollenaar method (E. S. R., 64, p. 14), based on air pressure, for forecasting rainfall in relation to tobacco planting in Java, and reports results of tests of the method for which a considerable degree of accuracy is claimed.

SOILS—FERTILIZERS

The Third International Congress of Soil Science, F. E. Hance (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 40 (1936), No. 2. pp. 127–136*).—"This paper is essentially a résumé of notes made by the author while in attendance at the sessions of the Third International Congress of Soil Science in England. Topics discussed are: Soil survey; soil reaction; acid-forming nitrogenous fertilizer; the functions of calcium in (1) base replacement, (2) correction of soil acidity, (3) amelioration of soil colloids, and (4) in the conservation of applied potash; manganese; and estimations of active chemical factors in plant nutrition."

[Soil and fertilizer studies by the Indiana Station] (*Indiana Sta. Rpt. 1935, pp. 14, 15, 56, 57, fig. 1*).—Data are given as to the results of fertilizer trials on the Purdue-Vincennes Farm, the improvement of southeastern In-

diana upland flats, the fertilization of muck soils, a study of the Pierre method for the determination of equivalent acidity and basicity of fertilizers, the use of the Neubauer method in determining fertilizer requirements of soils, and determination of the available potash in mixed fertilizers.

[Soils and crops work by the Indiana Station: Moses Fell Annex Farm], A. T. WIANCKO and G. P. WALKER (*Indiana Sta. Circ. 219 (1936), pp. 6–10*).—This circular contains, for the 1934 season, the usual annual report (E. S. R., 72, p. 13) on the general fertility test and the comparison of various phosphates.

[Soil and fertilizer studies by the Rhode Island Station] (*Rhode Island Sta. Rpt. [1935], pp. 23, 26*).—Data are reported on the effect of crops on soil acidity and on the basicity of dolomite and colloidal, rock, and calcined phosphates.

[Soil and fertilizer studies of the Tennessee Station], W. H. MACINTIRE (*Tennessee Sta. Rpt. 1934, pp. 16–19*).—Results are briefly noted from a laboratory study of the liming of soils, the absorption of calcium and magnesium by soils, the direct solubility of calcic and magnesic materials in rainwater, lysimeter experiments, lime-potash absorption studies, the influence of limestone and dolomite on superphosphate, sulfate conservation, the utilization of nitrogenous materials, and the production and properties of dicalcium phosphate.

[Soil Survey Reports, 1930 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1930, Nos. 40, pp. 55, pls. 2, figs. 2, map 1; 41, pp. 35, figs. 2, map 1*).—These reports were prepared with the cooperation of the Ohio Experiment Station.

No. 40. *Soil Survey of Brown County, Ohio*, E. D. Fowler and T. C. Green.—Brown County, in southwestern Ohio, has an area of 316,800 acres. Its land surface is that of a broad undulating plain, dissected by the Ohio River and its tributaries. The 22 soil series represented are subdivided into 26 types and numerous phases. Rossmoyne silt loam, which covers 21.5 percent of the area surveyed, Clermont silt loam, of which 18.7 percent was found, and Avonburg silt loam, which amounts to 16.8 percent, are the most extensive types listed. A section on the management of the soils of the county, by J. A. Slipher et al., is included.

No. 41. *Soil survey of Putnam County, Ohio*, A. E. Taylor et al.—Putnam County, in the northwestern part of Ohio, has a land area of 308,480 acres and lies largely in a level plain described as part of an old glacial lake basin. Most of the drainage waters empty into Lake Erie.

The soils form 19 series, inclusive of 34 types, the more extensive of these soils being Pandora silty clay, covering 12 percent of the area of the county, Brookston clay, forming 11.9 percent, and Paulding silty clay, amounting to 11.8 percent.

[Soil Survey Reports, 1931 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1931, Nos. 16, pp. 36, pls. 2, figs. 4, map 1; 18, pp. 36, pls. 3, figs. 2, map 1; 19, pp. 60, pls. 3, figs. 3, map 1; 21, pp. 24, figs. 2, map 1*).—The surveys here noted were made with the cooperation, respectively, of the Montana, Indiana, and Arizona Experiment Stations, and the North Carolina Department of Agriculture and Station.

No. 16. *Soil survey of the Gallatin Valley area, Montana*, W. DeYoung and L. H. Smith.—The Gallatin Valley area covers 513,280 acres, about 30 percent of the land included within the boundaries of Gallatin County, southwestern Montana, and the greater part of the farming land. The area occupies a basin partly enclosed by high mountains and is "one of the most important agricultural areas of the northern Rocky Mountain States." Irrigation water is provided by the Gallatin River and its larger tributaries.

The soils of the area were found to form 12 series containing 22 types and several variant phases of some of these types. Manhattan very fine sandy loam, which occupies 12.5 percent of the area, is the most extensive type listed. Rough broken and mountainous lands were found to the extent of 25.3 percent.

No. 18. *Soil survey of Randolph County, Indiana*, W. H. Buckhannan et al.—Randolph County, lying in the central position against the eastern boundary of Indiana, occupies 286,080 acres of the nearly level lands in the late Wisconsin glacial drift region. The soils consist of 14 series and include 16 types. Brookston silty clay loam occupies 26.1 percent of the area examined, Crosby silt loam 25.7 percent, Crosby silty clay loam 19.9 percent, and Miami silt loam 11.5 percent. A section of the report by A. T. Wiancko and S. D. Conner deals with the management of the soils of the county.

No. 19. *Soil survey of the Tucson area, Arizona*, F. O. Youngs et al.—The Tucson area, southeastern Arizona, occupies 276,480 acres and consists largely of stream valleys with narrow strips bordering them. Irrigation is necessary, and "the present trend in cultivated acreage is downward."

Soils of 16 series and 45 types were found, the most extensive type being Tucson loam, which covers 8.9 percent of the area included in the survey.

No. 21. *Soil survey of Franklin County, North Carolina*, W. A. Davis et al.—Franklin County is an area of 314,880 acres in north-central North Carolina. It varies in surface relief from nearly level to strongly rolling and depends mainly on the Tar River for its drainage.

The soils consist of Appling coarse sandy loam to the extent of 29.4 percent, with Cecil sandy loam 11.5 percent, Cecil coarse sandy loam 10.9 percent, Appling sandy loam 10.1 percent, and others of minor importance, making a total of 9 series, including 13 types. Unclassified lands include meadow 3.8 percent.

[Soil Survey Reports, 1932 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1932, Nos. 6, pp. 39, pls. 2, figs. 2, map 1; 7, pp. 40, pls. 2, figs. 2, map 1; 8, pp. 25, pls. 2, figs. 2, map 1; 9, pp. 38, figs. 3, map 1*).—The four reports here noted cover surveys carried out with the cooperation, respectively, of the Virginia and Texas Experiment Stations, the North Carolina Department of Agriculture and Station, and the Texas Station.

No. 6. *Soil survey of Nansemond County, Virginia*, R. E. Devereux et al.—Nansemond County has an area of 270,720 acres in southeastern Virginia, flat to rolling in surface relief, and dependent for drainage upon the Nansemond and Blackwater Rivers.

Of the total area, 23.5 percent consists of swamp, peat, and tidal marsh, and a group of light-colored poorly drained soils embraces 20.9 percent of the county. Norfolk fine sandy loam, the most important cultivated soil, occupies 26.5 percent. In all, 7 series, including 18 types, were found.

No. 7. *Soil survey of Falls County, Texas*, M. W. Beck.—This area of 484,480 acres in east-central Texas has, in general, an undulating to rolling surface, but includes also some large bodies of flatlands. All drainage is to the Brazos River.

The soils listed in the report here noted were found to form 21 series of 27 types, the most extensive being Houston black clay, 17.6 percent, and Wilson clay loam, 10 percent.

No. 8. *Soil survey of Washington County, North Carolina*, W. A. Davis and K. V. Goodman.—Washington County, in northeastern North Carolina, consists of 221,440 acres of flat or nearly level lands, of which 54.1 percent are muck, peat, and swamp. Only a small part of the county has good natural drainage. Of classifiable soils, 7 series were found to include 12 types, of which Bladen loam, 9.5 percent, is the most extensive.

No. 9. *Soil survey of Hardeman County, Texas*, E. H. Templin and T. W. Glassey.—Hardeman County, northern Texas, covers 443,520 acres of the Rolling Plains region. Tillman clay loam, 11.5 percent, is the most extensive soil among 13 series of 27 types. Rough broken land is listed as covering 12.8 percent of the county, and it is stated that about one-fourth of the county is too rough for agricultural use.

Genesis and composition of peat deposits, B. D. WILSON, A. J. EAMES, and E. V. STAKER ([*New York*] *Cornell Sta. Mem. 188 (1936), pp. 13, fig. 1*).—Typical peat deposits of the intensively cultivated areas of New York were examined to ascertain their mode of formation and the effect of the underlying material on the botanical and chemical composition of the plant remains of the profile layers. Three of the profiles described are those of deposits having a surface layer of woody peat. Two are of immature deposits, one having a surface layer of fibrous peat, the other a surface layer of moss peat. Of the five deposits, three are underlain with calcareous material.

The nature of the material underlying a deposit is shown to affect the calcium content and the reaction of the profile layers. This relationship was more readily discernible, under the conditions of the investigation, than was the effect of the character of the underlying material on the botanical composition of the layers. Under conditions of comparative dryness, the presence of *Sphagnum* appears to be indicative of a deposit underlain with material of acid reaction.

Capillary conductivity measurements in peat soils, L. A. RICHARDS and B. D. WILSON (*Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 427–431, figs. 2*).—In a contribution from the [New York] Cornell Experiment Station an apparatus of improved design, which was used in measuring the capillary conductivity of water in peat soils, is described.

At low tensions the soils were found to possess capillary conductivities greater than those that have been reported for mineral soils. However, the capillary conductivity was found to become zero at lower tensions in the two peat soils studied than has been reported for mineral soils.

Difficulty was experienced in measuring the capillary conductivity of peat soils because of the length of time required for the moisture content of the soils to reach an equilibrium value at a given capillary tension.

Land relief, F. J. MARSCHNER (*U. S. Dept. Agr., Atlas Amer. Agr., 1936, pp. 6, figs. 4*).—This brief article summarizes the influence of land relief on the agricultural value and utilization of soils under the heads of major physiographic features, influences of land relief on climate, influence of land relief on soils, and direct influence of relief on land use. A large map showing the physical features of the United States is included.

The residual effect of fertilizers, R. L. COOK and C. E. MILLAR (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 227–234*).—From experiments continued for several years on various soil types in eastern Michigan, it is concluded, in part, that the effective period of a fertilizer application may range from 1 to 4 yr. This range is dependent, apparently, upon such factors as soil, weather, cultural methods, kind of crop, and quantity of fertilizer applied. Larger residual benefits have been obtained during a year immediately following one of low rainfall. The increased yields of oats and barley resulting from residual fertilizer have, in most cases, been great enough to pay for a considerable portion of the fertilizer applied for the preceding crop, and, in many cases, more than enough to pay the entire fertilizer bill. When small grain nurse crops have been liberally fertilized the residual fertilizer has been sufficient for the needs of the alfalfa during two harvest years, the increases in yield of alfalfa, in most cases, paying for all the fertilizer applied for the nurse crop. From 200- to 300-lb. applications of fertilizer on old stands of

alfalfa caused increased yields for at least 3 yr., although the increases during the third year were rather small.

Some effects of long-continued manure, fertilizer, and lime treatment on the composition of cropped soils, A. W. BLAIR and A. L. PRINCE (*New Jersey Stas. Bul. 604 (1936), pp. 24, figs. 18*).—Cylinder and field plat soils cultivated and cropped for from 25 to 35 yr., farm soils cultivated and given rather heavy fertilizer treatment for some years, and corresponding soils neither cultivated nor treated with fertilizers were comparatively examined, with results in part as follows:

"Continuous cropping even under good management and fertilizer treatment tends toward a depletion of the organic matter of the soil thus treated in comparison with the soil as it was when the experiment was started. This is shown in a slight lowering of the percentage of nitrogen, carbon, and loss on ignition. Where no fertilizer, manure, lime, or green manure has been used on field plats for 25 yr., the soil has become so depleted in fertility that it does not yield a crop big enough to be harvested. However, with heavy applications of farm manure—heavier than would be economical in general farming—the content of organic matter is gradually increased over a period of years. This is shown by an increase in the percentage of nitrogen, carbon, and loss on ignition. . . . A depletion of the organic matter is also noted generally when soils that are continuously cropped and fertilized are compared with corresponding soils not fertilized and cropped."

The phosphorus content was in general gradually increased under cultivation and fertilizer treatment.

The potassium content was somewhat affected by liming, but little increase in potassium content was effected by the prolonged application of fertilizers containing this element.

"It is evident that potato soils in the sections examined are, in the majority of cases, being enriched in total phosphorus, are not changed very much in total potassium, and are gradually losing in content of organic matter."

The effect of fertilizers and cropping upon the nature and amount of electrodialyzable bases in the soil, with particular reference to potassium, G. M. GILLIGAN (*Delaware Sta. Bul. 200 (1936), pp. 14*).—Plat soils continuously cropped and subjected to definite fertilizer treatments and liming during a period of 24 yr. were electrodialyzed in order to determine the influence of cropping and treatments upon the quantities of the bases removed by this method.

Both dialyzable and total calcium and magnesium were increased by applications of lime. Calcium constituted the greater part of the bases removed.

Applications of lime increased the dialyzable potassium and manganese. The total potassium content of the limed plats exceeded that of the unlimed. The effects of liming upon exchangeable potassium (as determined by neutral ammonium acetate) were similar "save in two cases in which the values for limed and unlimed soils were identical." The values for exchangeable potassium were somewhat lower than those for electrodialyzable potassium. "Applications of potash fertilizers were reflected in the amounts dialyzable and exchangeable. The plat receiving manure only contained the greatest amount of dialyzable potassium." "Definite conclusions as to the effect of liming upon the availability of potassium cannot be arrived at, since data relative to the actual amounts of this element withdrawn by the crops are not available. While liming appears to have been generally beneficial to the particular plats investigated, since both the replaceable and total potash of the limed plats exceed that of the unlimed and the yields increased, the actual differences are small. Furthermore, when the yields from all blocks were taken into consideration, it

was concluded that the addition of lime was significantly profitable only when used in conjunction with potassium."

"Additions of superphosphate were readily reflected in the amounts of phosphorus dialyzed. Liming increased the amounts dialyzable and with few exceptions decreased the total phosphorus as compared with the unlimed plats. There are indications that liming increases the availability of phosphorus."

"A decrease in losses by leaching from the limed soils is suggested in explanation of the results obtained for the particular plat soils investigated. No consistent relationship appears to exist between the colloidal content and amount of electrodialyzable bases. The amounts of bases removed by electrodialysis do not, in themselves, appear to furnish a sufficiently accurate index to the ability of the soil to supply nutrients to the plant."

Soil changes resulting from nitrogenous fertilization: A lysimeter study, M. F. MORGAN (*Connecticut [New Haven] Sta. Bul. 384 (1936), pp. 367–449, figs. 8*).—This bulletin reports upon a detailed and thorough investigation of the effects of sodium nitrate, ammonium sulfate, urea, and cottonseed meal upon the drainage loss from the surface 7 in. of four soils having various textures and the following base exchange capacities and percentages of saturation with bases: Enfield very fine sandy loam—base exchange capacity 6.91 milliequivalents per 100 g of soil and 21.6 percent base saturated; Merrimac loamy sand—base exchange capacity 3.24 m. e. per 100 g of soil and 29 percent base saturated; Wethersfield loam—base exchange capacity 7.95 m. e. per 100 g of soil and 55.6 percent base saturated; and Merrimac sandy loam—base exchange capacity 5.13 m. e. per 100 g of soil and 38 6 percent base saturated.

The soils were held in exterior lysimeters under natural climatic conditions for 5 yr. The tanks were cylindrical, 20 in. in diameter, and contained a layer of 7 in. of surface soil over a conical drainage bed of coarse quartz sand. Drainage water was collected after each period of leaching, and composites were analyzed at semiannual periods.

The treatments supplied 200 lb. of nitrogen and other materials furnishing a total of 100 lb. of phosphoric acid (P_2O_5) and 200 lb. of potash (K_2O) per acre per year. The fertilizer was applied on May 26 of each year. The soils in the surface soil tanks were kept fallow. At the same time a separate series of tanks of the Merrimac sandy loam soil 20 in. in depth received the same treatments and was cropped to tobacco each year.

"The four soils have shown marked variations in amounts of dainage water, especially during the summer-fall period. The Merrimac loamy sand was the most leachy in performance. The Merrimac sandy loam soil retained practically the same proportion of the rainfall as the much heavier Wethersfield loam. The Enfield very fine sandy loam was definitely more resistant to leaching than the other three soils. For the 5 yr. the summer-fall leachings were 30.5 percent of the rainfall, while those from the winter-spring period were 51.2 percent of precipitation as an average of the four soils. These results were obtained with an average annual rainfall of 35.96 in., which was 8.11 in. below the 62-yr. average."

"A comparative summation of determined basic and acidic constituents showed an excess of anions on all soils and treatments except the nitrate of soda and urea treatments on the Wethersfield loam soil. This trend has been consistent in practically every period of analysis. The excess of acidic constituents over determined bases has been highest on sulfate of ammonia tanks and has also shown a correlation in magnitude with the initial degrees of base-unsaturation of the various soils. The source of this discrepancy is not definitely established. It may be due in part to iron for the sulfate of am-

monia treatments, but this explanation is inconsistent with the uniformly smaller predominance of anions for urea as compared with cottonseed meal."

A study of the availability of ammoniated superphosphate and various unusual phosphatic carriers by means of vegetative pot tests, B. E. GILBERT and F. R. PEMBER (*Rhode Island Sta. Bul. 256 (1936), pp. 24*).—"The relative availability of a number of unusual phosphate carriers was estimated by means of the dry weight yields of barley, oats, clover, and millet grown in soil in Wagner pots. The majority of the chemicals were supplied by the Bureau of Chemistry and Soils of the U. S. Department of Agriculture, and cooperation was maintained with this Bureau throughout the entire period of the tests."

When compared with monocalcium phosphate as 100, precipitated dicalcium phosphate gave a relative yield of 95, treble superphosphates prepared from ground dolomite and phosphoric acid or from ground limestone and phosphoric acid 91, 88, and 88, calcined phosphate 82, dimagnesium phosphate 79, calcium pyrophosphate 67, and ammoniated superphosphates prepared from various sources 61 percent.

Tricalcium phosphate, steamed bonemeal, and magnesium ammonium phosphate showed availabilities of 45, 45, and 41 percent, and "should be considered as having fertilizer possibilities". Aluminum phosphate (unignited) showed 36, boneblack 29, aluminum phosphate (ignited) 27, Ruhm phosphate 25, and ferric phosphate (ignited) 18 percent.

The results of determinations of phosphoric acid removed by the growth of the crop and of determinations of the theoretical availability of the carriers agreed well with the availability as indicated by crop growth.

Movement of lime in soils as determined by soil reaction, A. G. WEIDEMANN (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 254–259*).—Colorimetric acidity tests were made in various parts of the plowed layer of several soils that had been limed in different ways with varying quantities of several liming materials, and H-ion (pH) determinations were made electrometrically on a large number of samples taken at different depths from Hillsdale sandy loam soil that had been plowed once 2 yr. after liming and sampled 2 yr. after plowing. Similar determinations were made on Coloma sand sampled about a year after marl had been applied but not worked in.

"The data substantiate previous observations to the effect that there is a great tendency for lime to remain in that portion of the soil in which it is placed until mixed through the soil by tillage operations. So great is this tendency that 4 yr. after liming, and 2 yr. after plowing, highly alkaline soil areas were found very near soil testing 1.5 pH units lower. Marl which had been on the surface of a sandy soil for more than a year had neutralized the soil to a depth of not more than 2 in., although it had slightly affected the pH values of this soil to a depth of 6 or 8 in. These results illustrate the disadvantage of applying lime to the soil surface when the crop is growing or when for other reasons the lime cannot be worked into the soil.

"It is evident from the findings herein reported that a serious error may readily be made, through faulty sampling, in determining the lime requirements of a soil which has been limed previously."

Preliminary note on the inventory and balance sheet of plant nutrients in the United States, J. G. LIPMAN and A. B. CONYBEARE (*New Jersey Stas. Bul. 607 (1936), pp. 23*).—From a study of available data on soil gains in nitrogen, phosphorus, potassium, calcium, magnesium, and sulfur contents due to fertilizers and liming materials, manures and bedding, rainfall, irrigation waters, seeds, and nitrogen fixed and on losses brought about by harvested crops, grazing, erosion, and leaching, the authors arrived at figures showing an enormous annual net loss of plant nutrients from our soils. In addition to

heavy losses of potassium, calcium, and magnesium, they believe the net phosphorus loss per year to be "almost 10 times as much as is supplied by chemical fertilizers", and they find the nitrogen loss to be probably "more than 30 times the amount of nitrogen supplied by chemical fertilizers."

The depletions of soil plant food content discussed in the present bulletin "are of such a character as to call for the prompt adoption of measures which would offer to us assurance of more or less effective conservation and of a lessening drain on our resources of plant nutrients. Changed methods of soil management which would include proper provision for lessening the losses due to erosion and leaching would represent a major conservation measure. Such changes in our soil and crop management systems as would permit a lessening in the run-off, an increase in the amount of water stored in the soil, an increase in the area occupied by legumes, an increase in nonsymbiotic nitrogen fixation, and a decrease in the excessive oxidation of organic matter would almost, if not quite, permit the elimination of the annual deficit in respect to our soil nitrogen resources."

Synthetic manure production in Michigan, L. M. Turk (*Michigan Sta. Circ. 157 (1936), pp. 11, fig. 1*).—The author finds that the annual rainfall in Michigan is sufficient to produce a good grade of synthetic manure within a period of from 8 to 10 mo. during a normal season. If water is added to the compost, it will hasten the rotting process, however; and in this manner manure may be produced within 4 or 5 mo. Temperature did not appear to be a limiting factor in the production of synthetic manure except in months when the composts may be frozen over half way down from the top. During these winter months decomposition was found to be very slow.

"One ton of dry straw will produce about 2½ tons of wet manure. The total cost of the fertilizer ingredients is approximately 70 ct. per ton of wet manure, or $1.75 for the total cost of the chemicals to treat the original ton of dry straw. If straw is used in making synthetic manure, it will be more desirable to apply the chemicals at threshing time. This makes unnecessary the rehandling of the straw. The synthetic manure is equal or superior to barnyard manure in increasing crop yields."

AGRICULTURAL BOTANY

International rules of botanical nomenclature (*Jena: Gustav Fischer, 1935, 3. ed., pp. XI+152*).—International rules of botanical nomenclature were adopted by the International Botanical Congresses of Vienna, 1905, and Brussels, 1910, revised by the International Botanical Congress of Cambridge, 1930, and compiled by the editorial committee for nomenclature from the report of the subsection of nomenclature prepared by J. Briquet. The English version is by A. B. Rendle, the French by B. P. G. Hochreutiner, and the German by H. Harms. Supplements are provided on "nomina generica conservanda proposita", and on "species lectotypicae propositae", the specific parts of which are by various authors. There is also a brief summary of the more important changes in the rules from the second edition, by H. Harms, and an analytical index.

A new rapid method for the determination of living, killed, and injured tissues of green plants [trans. title], F. F. Mazkov (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 1 (1936), No. 6, pp. 265, 266*).—Proceeding from observations on the browning of dead leaves with acid sap—a generally known fact explained by loss of protoplasmic impermeability after death—the author submerged the chlorophyll-bearing tissue to be tested in a weak (from 0.1 to 0.3 N) hydrochloric acid solution. After from 15 to 20 min., the dead tissue

could be distinguished infallibly from the living by the browning of the former. Injured, but not entirely killed, tissues exhibited scattered brown flecks. The method proved both rapid and successful.

The nuclear crushing method [trans. title], E. HEITZ (*Ber. Deut. Bot. Gessell., 53 (1935), No. 10, pp. 870–878, pl. 1, fig. 1*).—Methods of cytological study without recourse to the microtome are reviewed, and a rapid method involving the crushing of plant tissues, successfully used by the author, is described.

Simple apparatus for the quantitative determination of photosynthetic and respiratory ratios, B. S. MEYER and D. S. RADER (*Plant Physiol., 11 (1936), No. 2, pp. 437–448, fig. 1*).—The apparatus described in this contribution by Ohio State University depends, in principle, on the measurement of changes in volume of the CO_2 gas present in the apparatus by absorption in a KOH solution and on the measurement of changes in a volume of the oxygen gas present by manometric means. Results of sufficient quantitative exactness to demonstrate clearly the important principles regarding photosynthetic and respiratory ratios are easily obtained, and representative determinations made with this equipment are tabulated.

The preparation of "three-colour" strips for transpiration measurements, F. Y. HENDERSON (*Ann. Bot. [London], 50 (1936), No. 198, pp. 321–324, fig. 1*).—Directions are given for the preparation and use of a modification of the Livingston and Shreve technic (E. S. R., 37, p. 26) for the application of cobalt chloride paper to transpiration measurements.

Micro-scale for a microscopic determination of pH, Z. E. BEKKER (*Bot. Zhur. S. S. S. R. (Jour. Bot. U. R. S. S.), 20 (1935), No. 4, pp. 348–352, fig. 1; Eng. abs., p. 352*).—"This scale is glued upon a cover glass fixed in a metallic ring and can be easily introduced into the ocular of any kind of microscope like an ocular micrometer."

Rice bran extracts and the growth of microorganisms, R. W. DUNN and A. J. SALLE (*Jour. Bact., 31 (1936), No. 5, pp. 505–516*).—In this study from the University of California rice bran was found to contain a stimulating substance or substances for carbohydrate-fermenting bacteria and for yeasts. Old extracts showed less stimulating ability for both bacteria and yeasts, while fresh extracts prepared from fresh or old bran were equally effective on bacteria but only those from fresh bran gave good yeast stimulation.

With the possible exception of phosphate, these extracts contained all substances necessary for the growth of *Escherichia coli* and many other organisms. Better growth of most organisms was obtained with buffered extract medium than with ordinary bacteriological infusion medium. The use of 0.1 percent peptone rice bran extract medium is recommended for obtaining better growth and increasing the growth rate of carbohydrate-fermenting bacteria.

Control of sexual reproduction in Phytophthora cactorum, L. H. LEONIAN (*Amer. Jour. Bot., 23 (1936), No. 3, pp. 188–190*).—*P. cactorum* grew in a synthetic medium consisting of the essential salts plus a pure grade of dextrose only on addition of proteose peptone or certain other organic substances. Not all growth-promoting substances proved capable of inducing sexual reproduction, but when exposed to a few cubic centimeters of pea infusion for as little as 1 hr. the fungus developed both oogonia and antheridia. On the other hand, certain substances, e. g., even such good growth-promoting substances as peptone, inhibited sexuality. The carry-over effect of the growth- and sexuality-promoting substances proved to be considerable.

The results of this study appear to indicate that this fungus is unable to synthesize growth- and sexuality-promoting substances.

Flattened chlorophyll disks as structural assimilation units of chloroplasts.—Preliminary contribution [trans. title], E. HEITZ (*Ber. Deut. Bot. Gesell., 54 (1936), No. 5, pp. 362–368, pl. 1*).—From a review of the literature, together with the results of the preliminary cytological study here reported, it is concluded that certain disks observed within the chloroplasts are in reality chlorophyll platelets.

The role of light in the life of plants.—II, The influence of light upon growth and differentiation, P. R. BURKHOLDER (*Bot. Rev., 2 (1936), No. 3, pp. 97–172, figs. 4*).—In this monographic review, under "growth" the author discusses light and darkness, cell multiplication and enlargement, the action of growth substance, and growth of the plant as a whole in relation to light intensity, duration, and quality. Under "differentiation", the discussion includes the plant axis, growth regions, tissue differentiation, leaves, reproduc tion, sex reversal and rejuvenation, and differentiation of the plant as a whole. A literature list of 600 titles is included.

Effect of light intensity on the manganese content of plants, M. M. MCCOOL (*Contrib. Boyce Thompson Inst., 7 (1935), No. 4, pp. 427–437, figs. 2*).—In experiments with soybean and buckwheat outside and with soybean, snap bean, and tobacco in a greenhouse, the visible injury (foliar brown spots and chlorosis) to the plants grown in manganese-treated soil decreased as the light intensity lessened. Except for tobacco, the decrease in yields induced by the manganese sulfate was not prevented by shading.

The percentage of manganese in the leaves of soybean and buckwheat plants from the outside experiment decreased consistently with the lessening of light intensity. In the greenhouse test the manganese content of soybean leaves decreased with increase in degree of shading, as did that of equal areas of the first leaves to develop, but the effect of shading on the amount in equal areas of the second and third leaves was less marked. The content in equal areas of snap bean and tobacco leaves decreased with lessening intensity of light. The percentage of manganese in the stems of plants grown in soil treated with 400 p. p. m. of manganese sulfate varied only slightly, but it increased with the degree of shading in those grown in soil receiving 600 p. p. m. The manganese content of the roots of snap beans and tobacco was remarkably high, although shading decreased it in the tobacco.

Response of certain plants to length of day and temperature under controlled conditions, R. A. STEINBERG and W. W. GARNER (*Jour. Agr. Res. [U. S.], 52 (1936), No. 12, pp. 943–960, figs. 3*).—The responses to day length and temperature of the Biloxi, Peking, and Mandarin varieties of soybeans and of sugar beets and *Rudbeckia bicolor* were studied in an accurately controlled environment with tungsten filament lamps as the light source. The equipment gave readily reproducible results agreeing closely with those obtained in a more natural environment. Within suitable limits, increase in temperature somewhat decreased the range of critical day lengths and slightly increased the range of optimum day length in soybeans, while in sugar beets increased day lengths markedly compensated for unfavorable high temperatures, and the converse was true to a considerable extent. Biennial behavior in the sugar beet is not inherent but results primarily from conditions of day length and temperature unfavorable to reproduction. Though beets require a lower temperature range for flowering than the other long-day type, *Rudbeckia*, the two otherwise behave quite similarly in that within favorable ranges an increase in temperature accelerates reproduction. The temperature responses of the three varieties of soybeans were relatively uniform and but slightly correlated with their behavior as late, medium, and early forms, whereas the marked differences in critical day lengths for flowering agreed

closely with their behavior in nature. The quantitative data on flowering and growth at the several temperature levels and day lengths are given in detail.

Influence of length of day (photoperiod) on development of the soybean plant, var. Biloxi, A. E. MURNEEK and E. T. GOMEZ (*Missouri Sta. Res. Bul. 242 (1936), pp. 28, figs. 27*).—During the early stages, short-day (7-hr.) plants were lighter in color but soon matched with the long-day (14-hr.) plants, and at the time of sexual reproduction became intensely green. Seedlings of both groups, up to 14 days of age, were similar in rate of growth and development of organs, but from about that time the 14-hr. plants began to grow faster and were soon much taller, with thicker, softer stems and larger leaves. During the same period, the 7-hr. plants increased little in height but initiated and developed numerous flower buds on short, axillary shoots. The primary meristem region was almost obliterated as a result of the reduced internodes, making some of the flower buds and flowers appear terminal.

Histological observations of plants 21 or more days old indicated marked differences in development of the promeristem and internodes of the main stem and axillaries and in the rate of formation and maturation of the tissues produced from the promeristem of the plants in the two groups, details of which are given. In the 14-hr. plants, maturation of the meristematic cells was markedly delayed, thus providing for the initiation and further growth of various organs. Both the promeristematic and meristematic cells of the 7-hr. plants were larger but fewer than those of the 14-hr. plants, and mitotic figures were rarely seen.

The development of the axillary buds of both groups was similar up to the twenty-first day. The earliest sign of initiation of the first potential and possibly actual flower buds was in the 14-day-old plants exposed to the 7-hr. photoperiod, and unmistakable signs were evident at 21 days. On the twenty-fifth day, many flower buds had already reached a stage where the primordia of various floral organs and the early growth stage of the calyx were distinguishable histologically, and a week later many of these organs were visible to the unaided eye. On the forty-second day, a large number of buds had reached their maximum size and there were flowers in anthesis. The 14-hr. plants remained vegetative, with no sign of reduction in growth or initiation of reproductive organs.

Photoperiodic responses of certain greenhouse annuals as influenced by intensity and wavelength of artificial light used to lengthen the daylight period, R. B. WITHROW and H. M. BENEDICT (*Plant Physiol., 11 (1936), No. 2, pp. 225–249, figs. 9*).—The plants used in these studies at Purdue University were pansy (*Viola tricolor*), stock (*Matthiola incana*), and China-aster (*Callistephus chinensis*); the intensities of incandescent lamp radiation were 100, 10, 1, 0.3, and 0.1 footcandles; and the wavelengths included blue (380–510 mμ), green (455–550 mμ), yellow (530–650 mμ), orange red (650–? mμ), red (680–? mμ), extreme red (720–? mμ), and infrared (800–? mμ).

As to intensity, but little response differences were secured between 100 and 10 footcandles, and a very definite photoperiodic effect was induced by 0.3 footcandle and as low as 0.1 footcandle with China-aster. An increase in dry weight over the control was induced in all three species under all intensities of artificial radiation used. An increase in the top:root ratio also occurred in pansy and stock with increase in intensity.

As to wavelength, the orange and red caused the most marked photoperiodic response in all three species. The earliest blooming with pansy and stock and the most flowers with all three species occurred under these bands (especially the orange red), and in stock the greatest departure in branching habit. But little effect on flowering time occurred in pansy and stock under the blue, green,

or yellow, but in aster all wavelengths of additional light induced earlier flowering. The top: root ratio in all three species was greater under all wavelengths, the greatest ratio occurring under the orange red. The fresh weight was also greatest under orange and red radiation.

Biological effects of radiation: Mechanism and measurement of radiation, applications in biology, photochemical reactions, effects of radiant energy on organisms, and organic products, edited by B. M. DUGGAR (*New York and London: McGraw-Hill Book Co., 1936, vols. 1, pp. X+676, figs. 117; 2, pp. VII+677–1343, figs. 52*).—These volumes constitute a collective contribution, developed as a byproduct of activities of a committee now known as the Committee on Radiation, National Research Council, aiming to bring together "in the form of a survey a collation of the available material—theoretical, factual, and methodological—" to represent the present status of scientific knowledge in the five aspects chosen, viz, physics, photochemistry, certain biological products, zoology, and botany. The survey purposely excludes to a large extent practical considerations relating to plant production and certain other phases of applied radiology. Copious bibliographic references appear at the ends of chapters, and a subject index and alphabetical list of contributors are provided. The subject matter is taken up under the following chapter headings:

Photons and Electrons, by K. K. Darrow (pp. 1–42); Measurement of X-rays and Radium, by L. S. Taylor (pp. 43–85); Ionization and Its Bearing on the Biological Effects of Radiation, by G. Failla (pp. 87–122); Measurement and Application of Visible and Near-Visible Radiation, by F. S. Brackett (pp. 123–209); The Intensity of Solar Radiation as Received at the Surface of the Earth and Its Variations With Latitude, Altitude, the Season of the Year, and the Time of Day, by H. H. Kimball and I. F. Hand (pp. 211–226); Statistical Treatment of Biological Problems in Irradiation, by L. J. Reed (pp. 227–251); Photochemistry, by F. Daniels (pp. 253–302); The Effect of Radiation on Proteins, by J. H. Clark (pp. 303–322); Radiation and the Vitamins, by C. E. Bills (pp. 323–340); The Effects of Irradiation on Venoms, Toxins, Antibodies, and Related Substances, by S. C. Brooks (pp. 341–388); The Effects of Radium and X-rays on Embryonic Development, by E. G. Butler (pp. 389–410); Effects of X-rays and Radium Upon Regeneration, by W. C. Curtis (pp. 411–457); The Biological Effectiveness of X-ray Wave-Lengths, by C. Packard (pp. 459–471); The Physiological Effects of Radiation Upon Organ and Body Systems, by S. L. Warren (pp. 473–539); Short Electric Wave Radiation in Biology, by G. M. McKinley (pp. 541–558); Biological Effects of Alpha Particles, by R. E. Zirkle (pp. 559–572); Motor Responses to Light in the Invertebrate Animals, by S. O. Mast (pp. 573–623); The Action of Radiations on Living Protoplasm, by L. V. Heilbrunn and D. Mazia (pp. 625–676); Photoperiodism, by W. W. Garner (pp. 677–713); Plant Growth in Continuous Illumination, by J. M. Arthur (pp. 715–725); The Effects of Light Intensity Upon Seed Plants, by H. L. Shirley (pp. 727–762); Effects of Different Regions of the Visible Spectrum Upon Seed Plants, by H. W. Popp and F. Brown (pp. 763–790); Effect of the Visible Spectrum Upon the Germination of Seeds and Fruits, by W. Crocker (pp. 791–827); The Effects of Visible and Ultra-violet Radiation on the Histology of Plant Tissues, by J. T. Buchholz (pp. 829–840); Some Infrared Effects on Green Plants, by J. M. Arthur (pp. 841–852); The Effect of Ultra-violet Radiation Upon Seed Plants, by H. W. Popp and F. Brown (pp. 853–887); The Effects of Radiation on Fungi, by E. C. Smith (pp. 889–918); The Problem of Mitogenetic Rays, by A. Hollaender (pp. 919–959); Effects of X-rays Upon Green Plants, by E. L. Johnson (pp. 961–985); The Effects of

Radium Rays on Plants, by C. S. Gager (pp. 987–1013); The Light Factor in Photosynthesis, by H. A. Spoehr and J. H. C. Smith (pp. 1015–1058); The Influence of Radiation on Plant Respiration and Fermentation, by C. J. Lyon (pp. 1059–1072); Growth Movements in Relation to Radiation, by E. S. Johnston (pp. 1073–1091); Chlorophyll and Chlorophyll Development in Relation to Radiation, by O. L. Inman, P. Rothemund, and C. F. Kettering, (pp. 1093–1108); Radiation and Anthocyanin Pigments, by J. M. Arthur (pp. 1109–1118); Effects of Radiation on Bacteria, by B. M. Duggar (pp. 1119–1149); The Effects of Radiation on Enzymes, by H. A. Schomer (pp 1151–1165); Induced Chromosomal Aberrations in Animals, by T. Dobzhansky (pp. 1167–1208); Radiation and the Study of Mutation in Animals, by J. Schultz (pp. 1209–1261); Induced Mutations in Plants, by L. J. Stadler (pp. 1263–1280); Induced Chromosomal Alterations, by T. H. Goodspeed (pp. 1281–1295); Induced Chromosomal Alterations in Maize, by E. G. Anderson (pp. 1297–1310); and Biological Aspects of the Quantum Theory of Radiation Absorptions in Tissues, by J. W. Gowen (pp. 1311–1330).

Leaf temperatures and the cooling of leaves by radiation, O. F. CURTIS (*Plant Physiol., 11 (1936), No. 2, pp. 343–364, figs. 7*).—From these studies at Cornell University, it is concluded that "leaf temperatures may be considerably influenced by exchange of infrared radiation between the leaf and other materials near or at a distance from it. There may also be loss of heat by radiation to space. These effects are independent of the temperature of the air in the vicinity of the leaf because the oxygen and the nitrogen of the air are almost transparent to infrared radiation. It has been demonstrated, both under laboratory and field conditions, that leaf temperatures may be rapidly changed several degrees by allowing or preventing radiation to cold objects or to space. Rapid and great changes in temperature of leaves in direct sunlight are also brought about by natural or artificial changes in rates of air flow or light intensity. The presence of water in the atmosphere either as vapor or clouds may influence plant temperatures through its effect on infrared radiation. Data which have been taken by various investigators to demonstrate that leaves in direct sunlight may be cooler than the air are questioned on the basis that the readings for air temperatures were probably too high."

Seasonal study of tissue function and organic solute movement in the sunflower, O. A. LEONARD (*Plant Physiol., 11 (1936), No. 1, pp. 25–61, figs. 6*).—In this diurnal and seasonal study of sunflower plants at the State College of Washington, the sensitivity of young leaves to carbohydrate fluctuations was found to be not much greater than for old leaves, and high reducing sugar values in the former did not result in much higher sucrose values. Marked differences occurred between the carbohydrate proportions of leaves grown in Washington and in Michigan.

In both old and young leaves (1934 series) the simple sugars accounted for from one-third to one-half of the carbohydrates. The high sugar concentrations and fluctuations in the leaves were correlated with much smaller sucrose concentrations, favoring the idea that simple sugars are the first photosynthetic products.

Positive sucrose gradients were obtained for the bark—believed to be associated with the water percentage there rather than as indicating that sucrose is moving from "source" to "sink" on a gradient plan. The sucrose gradient from the head into the seed was negative—again associated with the percentage of moisture. The wood stored sucrose predominantly, and the pith the simple sugars—both also correlated with the moisture percentages. Simple sugars reached a maximum during the opening of the head and for a short time

thereafter. The pith was active in the synthesis of organic nitrogen (amino acids being most important) and also as a storage tissue. It was essentially void of sugars until flowering and early seed development. Nitrates were stored in the pith either early or late in the season, but during rapid growth of the head the nitrates stored early in the season decreased. Starch was almost absent from all parts of the plant except in the leaves during the day, at which time it, together with the acid-hydrolyzable material, removed from solution a part of the excess sugar not immediately translocated. The acid-hydrolyzable material, appearing as a temporary form, was nearly all translocated at night.

The diurnal fluctuations of soluble organic nitrogen in the leaves suggested that synthesis may occur there, and the low concentrations of ammonium and nitrate nitrogen suggested a rapid conversion of these forms into organic nitrogen. The data at least suggest that some of the organic nitrogen is synthesized outside the leaves, the most active regions appearing to be the upper pith and the head. Gradients of soluble nitrogen out of the leaves into the bark were always positive, but those of total soluble, amino, and ammonium nitrogen were nearly always negative up the stem (true for the bark, wood, and pith). Possibly some of the gradients appearing negative on a gross macrochemical basis were actually positive on the surface of colloids. Amides were often absent and never very abundant, and ammonium nitrogen was probably present as ammonium salts or held to the surface of colloids. As the seeds mature, large amounts of unused organic nutrients may collect in the different plant parts, this being most noticeable in the upper regions. The hourly moisture fluctuations in the leaf blades were not great, but the moisture content of the older leaves was always greater than that of the young leaves.

Effects of nutrient concentration on anatomy, metabolism, and bud abscission of sweet pea, G. T. NIGHTINGALE and R. B. FARNHAM (*Bot. Gaz., 97 (1936), No. 3, pp. 477–517, figs. 21*).—Plants in the more dilute solutions grew vigorously and were relatively succulent, the leaf blades were thin, somewhat circular in shape and dark green, and a comparatively high percentage of flower buds abscissed. Those in the more concentrated solutions grew less vigorously and were less succulent, the leaf blades were thick, oval or elliptical in shape, and light green, and a comparatively low percentage of flower buds abscissed. The roots and tops of plants in the less concentrated solutions were high in young, active cells with dense protoplasm, all tissues differentiated and matured slowly, carbohydrates were relatively low and organic nitrogen was high, a large part of the elaborated nitrogen occurred as amide and amino nitrogen, and nitrate was abundant. In the concentrated solutions all organs were relatively low in young cells with dense protoplasm, tissues differentiated and matured slowly, strongly developed fibers and other mechanical elements were present, carbohydrates were high and organic nitrogen was relatively low, a large part of the elaborated nitrogen occurred as complex proteins, and nitrate was abundant.

The anatomic, metabolic, and abscission phenomena are described in detail, the relationships of soil moisture and salt concentration are discussed, and the significance of the data revealed is pointed out. Mature, optically empty tissues give a condition of protein deficiency incorrectly called nitrogen deficiency. Such effects are especially severe in fruit trees, some grasses, and other perennials, because they carry on the initial phases of nitrate assimilation and protein synthesis almost exclusively in the fine, succulent rootlets, which mature and lose the ability to manufacture protein very rapidly when exposed to relatively concentrated solutions of salts. However, the roots can absorb nitrate and other nutrients freely when present in the nutrient solution.

Further studies on the relation between the carbon assimilation and nitrogen fixation in leguminous plants, C. E. GEORGI, F. S. ORCUTT, and P. W. WILSON (*Soil Sci., 36 (1933), No. 5, pp 375–382*).—Supplementing previous studies at the University of Wisconsin (E. S. R., 69, p. 183), "red clover plants were supplied with the same total quantity of CO_2 but at different partial pressures. Marked increases in the dry weight formed, nitrogen fixed, and number of nodules were observed as the pressure was raised from 0.03 percent to 0.1 percent. The observed increases are due to an increase in the pCO_2 supplied the plants, and not to the total quantity available.

"Red clover plants supplied with glucose and sucrose in the nutriment solution show an increase in both dry weight and nitrogen fixed, even in concentrations of carbohydrate as low as 0.1 percent. However, higher concentrations of the carbohydrate are more effective. The increases are more marked in plugged containers in which carbon assimilation in the controls (no carbohydrate) is limited and in which gas diffusion is lowered. The effect is probably due to liberation of CO_2 by bacteria with consequent increase in the pCO_2 in the neighborhood of the plant, and to actual absorption of the carbohydrate. The addition of mannitol to inoculated red clover plants does not cause an increase in nitrogen fixed. Concentrations of 0.25 to 0.5 percent mannitol appear to have a detrimental effect on the fixation of nitrogen by red clover.

"Red clover and sweetclover plants inoculated with a nonhomologous species of rhizobia (one that does not infect the plant) die of nitrogen starvation, even though a source of energy (carbohydrate) is furnished the bacteria. This indicates that soluble nitrogen compounds capable of being used by the plant are not fixed by free-living forms of rhizobia."

Changes in carbohydrate content of wheat plants during the process of hardening for drought resistance, I. M. and M. G. VASSILIEV (*Plant Physiol., 11 (1936), No. 1, pp. 115–125*).—Five varieties were hardened for drought resistance by growth with insufficient water until permanent wilting and necrosis of leaf tips had set in. Recovery was then induced by irrigation.

Analyses showed that at the beginning of wilting, monosaccharides and sucrose were increased and hemicelluloses decreased. At permanent wilting sucrose was decreased, monosaccharides were increased, and hemicelluloses decidedly increased (above the controls). With the beginning of irrigation the water content rose, but not as high as the controls, and the soluble sugars were decreased. After 8 days of recovery the drought-treated plants were still lower in water content than the controls, monosaccharides were low, and sucrose and hemicelluloses were increased. The conditions seemed to have become "fixed" as a result of the treatment. The significance of hemicelluloses in drought resistance of wheat is discussed.

Glutamine metabolism of the beet, H. B. VICKERY, G. W. PUCHER, and H. E. CLARK (*Plant Physiol., 11 (1936), No. 2, pp. 413–420*).—In this study at the Connecticut [New Haven] Experiment Station, when beets grown either in the field or greenhouse were treated with liberal amounts of ammonium sulfate solution in the soil the glutamine content of the roots rapidly increased, although the asparagine content was not affected. Daily applications were most effective. At the stage of definite toxicity a glutamine concentration of 5.4 percent of the dry weight of the roots was attained, but there was little effect on the composition of the tops until after severe injury had occurred.

In beets glutamine acts as a primary detoxifying agent for ammonia, but the function of asparagine in the general metabolism is not yet clear. Both nitrogen atoms of glutamine share in the reaction, and it is thus inferred that the precursor of the glutamine is nonnitrogenous. The reaction is believed to

proceed in two stages—a primary formation of glutamic acid and then a dehydration of the ammonium salt of glutamic acid to the amide.

The essential nature of certain minor elements for plant nutrition, W. E. BRENCHLEY (*Bot. Rev., 2 (1936), No. 4, pp. 173–196*).—The conclusions from this review are that the available evidence indicates small amounts of boron and manganese to be essential for the growth and health of many, if not all, plant species. Copper and zinc are also necessary in many cases, though it is still uncertain whether this need is universal. Only isolated cases of improvement due to traces of other minor elements have thus far been established. However, it may be that specific elements are necessary for specific plants, and possibly the conclusive evidence in hand for boron and manganese may lead the way to further research with results of far-reaching scientific and economic importance. A bibliography of 173 titles is appended.

Some effects of the heavy metals essential for the nutrition of Aspergillus niger upon its growth, R. A. STEINBERG (*Amer. Jour. Bot., 23 (1936), No. 3, pp. 227–231*).—The ratios of the yields with iron, zinc, copper, and manganese to those with one of these elements omitted varied with the heavy metal concentration and reached their maxima at the optimum concentration for growth (at least in acid solutions). Ion toxicity was displayed by these metals with growth and sporulation even at high dilutions. At a pH value of 6.0 or above a marked increase in the apparent optima of the heavy metals for growth occurred, since they served both as nutrients and chemically to increase acidity. A shift in the maxima of the yield and pH curves to the lower nutrient concentrations may occur with delay in the time of harvesting.

Injury to plants by fluorine and fluorine-silicon salts [trans. title], S. M. MASHTAKOV (MASCHTAKOW) and K. I. STRACHITSKII (STRATSCHIZKY) (*Trudy Nauch. Inst. Udobr. i Insektofungisid. (Trans. Sci. Inst. Fert. and Insectofungicides [Moskva]), No. 123 (1935), pp. 184–190, figs. 7; Ger. abs., p. 288*).—The action of fluorine and silicon-fluorine preparations on plants was studied by the laboratory method of determining root growth and in the field by observations on the "burned" areas induced. The results by both methods were in full agreement. Most of the fluosilicates proved more toxic than the fluorine salts. The sodium salts were less toxic than the potassium salts.

GENETICS

Genetical studies of bacteria, I, II, C. C. LINDEGREN (*Zentbl. Ba't. [etc.], 2 Abt., 93 (1935), No. 1–3, pp. 40–47, figs. 2; 93 (1935), No. 5–8, pp. 113–122*).—These studies are described as follows:

I. *The problem of the bacterial nucleus.*—This is a critical, theoretical discussion, from which it is concluded that the problem of the structure of bacterial protoplasm resolves itself into whether bacterial protoplasm is something totally different from that in any other known living form or whether it is possible to demonstrate the presence of nuclear structure within it either by cytological or genetical technic.

II. *The problem of bacterial variation.*—It is concluded that, as in fungi, bacterial variation may result from the operation of six mechanisms: Modification, mutation, transmissible nongenic variation, heterokaryosis, life cycle changes, and hybridization. It seems possible that in the evolution of bacteria genes may have been selected which are capable of mutating to a series of allelomorphs, each of which adapts the organism to some specific environment. In view of the large populations, even a slow rate of mutation could produce genotypes to insure adaptation over a wide range of environments.

Morphological and cytological studies on Fagopyrum esculentum.—II, Embryogeny, K. L. MAHONY (*Amer. Jour. Bot., 23 (1936), No. 2, pp. 129–133, figs. 29*).—The second of the series (E. S. R., 74, p. 180) deals with a study of embryo development in *F. esculentum*.

Studies in the cytology of wheat and of a wheat species hybrid, E. S. HORTON (*Amer. Jour. Bot., 23 (1936), No. 2, pp. 121–129, pls. 2, figs. 7*).—Microsporogenesis in the durum wheat Iumillo (14_{II}) is described, and the prophases are compared with those of Iumillo × Marquis ($14_{II} + 7_{I}$).

A general review of the inheritance of wool-characters in sheep, W. C. MILLER (*Empire Jour. Expt. Agr., 1 (1933), No. 2, pp. 173–192*).—In a contribution from the Institute of Animal Genetics, Edinburgh, the inheritance of wool characters is reviewed, including research on the inheritance of wool fineness, length, crimp, fleece weight and density, kemp, and related characters.

Wool characters in "Half-bred" sheep (Border Leicester rams×Cheviot ewes), J. E. NICHOLS (*Jour. Agr. Sci. [England], 23 (1933), No. 3, pp. 473–484, pl. 1, figs. 5*).—A study of the character of the wool in the first and second generation of Border Leicester × Cheviot sheep showed that the parental types appeared in the F_1 and F_2 generations. Such segregation suggested a multiple factor interpretation for the mode of inheritance of wool characters.

Gene relationships in two species of mice with reference to their possible evolutionary significance, C. V. GREEN (*Amer. Nat., 69 (1935), No. 720, pp. 19–29*).—A comparison of the genes of *Mus bactrianus* with the mutant forms of *M. musculus* suggests that the basic genes are essentially the same in both species.

Quantitative characters in reciprocal hybrids, C. V. GREEN (*Amer. Nat., 69 (1935), No. 722, pp. 278–282*).—No consistent differences between reciprocal crosses involving *Mus bactrianus* and *M. musculus* (E. S. R., 72, p. 602) were noted. Thus support is not afforded for a plasmatic hypothesis for size inheritance.

Further data on the existence of extra-chromosomal influence on the incidence of mammary tumors in mice, W. S. MURRAY and C. C. LITTLE (*Science, 82 (1935), No. 2123, pp. 228–230*).—Data on four types of backcrosses involving the incidence of mammary tumors in mice, suggest that extra chromosomal influences play an important role in the incidence of mammary tumors (E. S. R., 74, p. 475).

Effects of the flexed-tailed gene on the development of the house mouse, R. J. KAMENOFF (*Jour. Morph., 58 (1935), No. 1, pp. 117–155, pls. 2, figs. 3*).—A histological study of the flexed-tailed mice described by Hunt (E. S. R., 68, p. 746) and normal mice showed that the fusion of the vertebrae was due to the failure of the early cartilage of the intervertebral disk to differentiate normally on the fourteenth to fifteenth day of gestation. This is also associated with a general retardation in the early growth of the flexed-tailed embryos and the occurrence of an anemic condition 14 days after fertilization.

The analysis of the organismal differentials of gray Norway rats and of two mutant races by means of transplantation, L. LOEB and H. D. KING (*Amer. Nat., 69 (1935), No. 720, pp. 5–18*).—Studies of the response of syngenesiotransplantations, homoiotransplantations, and intermutant transplants in gray Norway, mutant albino, and curly coat rats led to the conclusion that the differences in the severity of reactions between homoiogenous and interracial transplantations are real, and that single mutations such as cause change from gray Norway to curly coat may have a definite effect on the organismal differential.

A lethal mutation in the rabbit with stigmata of an acromegalic disorder, C. K. HU and H. S. N. GREEN (*Science, 81 (1935), No. 2088, pp. 25, 26*).—A lethal

mutation in the rabbit, resembling an acromegalic disorder and involving the appearance in the young animals of a faint redness with an edematous thickening of the skin over the nape of the neck, between the shoulders, at the base of the skull, behind the ears, or under the chin, and subsequently over the whole ventral surface of the body, was considered to be due to the operation of a single recessive factor. Some heterozygous normal males exhibited symptoms in early life. The condition fits in with the syndrome associated with over-activity of the growth-promoting hormone of the pituitary.

Experiments on inbreeding of poultry ([*Gt. Brit.*] *Min. Agr. and Fisheries Bul. 83 (1934), pp. V+59, figs. 5*).—Studies of the effects of father-to-daughter matings when the sire and dam were not brother and sister were carried out from 1925 to 1931 at the National Institute of Poultry Husbandry, England, with high-producing strains of White Wyandottes, Rhode Island Reds, and White Leghorns. Matings of the same sires with nonrelated birds served as controls. The results showed that the progeny of the inbred matings were generally inferior to the controls in vigor, annual production, fertility, and hatchability of the eggs, chick mortality, age and weight at sexual maturity, and laying house mortality.

A ten year inbreeding experiment in the domestic fowl, N. F. WATERS and W. V. LAMBERT (*Poultry Sci., 15 (1936), No. 3, pp. 207–218, figs. 9*).—The results are presented on the effects of inbreeding on vigor and egg production in three lines of Single Comb White Leghorns at the Iowa Experiment Station. The approximate amounts of inbreeding attained were 83, 61, and 41 percent in the different lines. Records were obtained on all female chicks that survived, but hatchability was an important character, for which selection was made in continuing the lines with other characters such as fertility, early maturity, egg size, body size, egg production, and viability considered insofar as practicable. Fertility, hatchability, and egg production were well maintained in all three lines, and the inbreeding seemed to have no general effect on egg size or earliness of maturity.

Inbreeding in the White Leghorn fowl, N. F. WATERS and W. V. LAMBERT (*Iowa Sta. Res. Bul. 202 (1936), pp. 55, figs. 32*).—This is a more detailed report of the effects of inbreeding in the domestic fowl on egg production, fertility, hatchability, and other characteristics of vigor than that noted above. Results are also included on a total of six inbred families.

Continued research upon variation and heredity of some characters in White Leghorns, Rhode Island Reds and Barnevelders, J. AXELSSON (*Lantbr. Högsk. Ann. [Uppsala], 1 (1933–34), pp. 69–207, figs. 6*).—A report is given of the variation in and heredity of egg weight in the crosses of White Leghorn, Rhode Island Red, and Barnevelder breeds, previously noted (E. S. R., 72, p. 603). The variability of the weight of the eggs laid by the different breeds and crosses between them is presented, together with the correlations of egg weight with seasonal and other conditions including breed relationships.

Positive correlations were obtained between the weights of the eggs laid by dams and daughters.

Correlations between egg production were also presented.

Some sex-linked crosses, R. T. PARKHURST, H. M. MOLYNEUX, B. CHAMBERLAIN, and F. H. JONES (*Poultry Sci., 13 (1934), No. 4, pp. 202–207*).—Experiences in the accuracy with which sex can be determined at hatching in birds produced in the following crosses are described: White Bresse × Single Comb White Leghorn; Single Comb Black Minorca × Single Comb White Leghorn; Single Comb Black Leghorn × Barred Plymouth Rock; Single Comb Black Leghorn × Single Comb Cuckoo Leghorn; Single Comb Cuckoo Leghorn × Single Comb Rhode Island Red; Brown Sussex × Light Sussex; and Single Comb Rhode

Island Red × Light Sussex. The use of shank color for sex determination did not prove of sufficient accuracy to be of economic value, but no difficulty was experienced in determining sex at hatching with the gold and silver matings, black and barred matings, and rate of feathering, provided the birds used were pure for the sex-linked factors involved.

Black beak was found to be inherited as a sex-linked dominant factor to horn beak color in the Black Leghorn × Cuckoo Leghorn cross.

A Brahma-Plymouth Rock mosaic, E. ROBERTS and J. H. QUISENBERRY (*Jour. Heredity, 26 (1935), No. 1, pp. 11–14, figs. 3*).—A mosaic with a Barred Plymouth Rock mother and probably a Brahma father showing the characteristics of the Plymouth Rock on the right side of the body and the Brahma on the left is described. The possibility of the condition being due to the loss of two autosomes is discussed.

Weight and size of organs in Frizzle fowl, W. LANDAUER and E. UPHAM ([*Connecticut*] *Storrs Sta. Bul. 210 (1936), pp. 42*).—In continuing studies of the weights of the organs in Frizzle fowls (E. S. R., 75, p. 613), a comparison was made of the weights of the blood, heart, lungs, spleen, liver, adrenals, kidneys, pancreas, crop, and gizzard lining, of the length and weight of the proventriculus, gizzard, duodenum, small intestine, ceca, and large intestine, and of the intestinal volume of three age groups of Leghorns and homozygous Frizzle fowls, averaging approximately 800, 485, and 160 days of age. Comparisons were considered of the ratio of organ weight to net body weight (weight with feathers removed), ratio of cube root of the organ weight to the length of the dorsum, and the ratio of the organ weight to the two-thirds power of the net body weight.

Considering the several indices of comparison, it is concluded that Frizzle chickens show definite increases in the relative weights of thyroids, heart, blood, spleen, kidneys, adrenals, pancreas, crop, and gizzard and in the capacity of the intestinal tract. Distinct differences in the fat deposits of Frizzle and normal chickens were observed. Young Frizzles were almost without fat deposits, while older Frizzles tended to have excessive fat accumulations. The increased rate of metabolism is associated with increased size of the thyroids and adrenals. Other changes in the organs were directly connected with the loss of body heat and increased metabolic rate associated with it.

Lessened water vaporization conserves body heat and is probably associated with the lack of enlargement of the lungs.

Although it is concluded that the Frizzle gene is directly responsible for only the plumage defect, it seems likely that residual heredity plays an important role in determining the degree of variation in organs and functions and their relation to survival.

Inheritance as a factor in poultry disease, W. V. LAMBERT (*Poultry Sci., 14 (1935), No. 3, pp. 131–136*).—A discussion of the possibilities of disease control through genetic methods, including findings indicative of promise with specific diseases.

The study of the conditions and factors affecting hair growth in the guinea-pig, D. H. STRANGEWAYS (*Jour. Agr. Sci. [England], 23 (1933), No. 3, pp. 359–378, pls. 2, figs. 7*).—Detailed studies show that hair growth on defined areas of the skin varies with the age and condition of the animal, season, and temperature.

The development of the mammary glands of the goat, C. W. TURNER and E. T. GOMEZ (*Missouri Sta. Res. Bul. 240 (1936), pp. 22, figs. 33*).—According to this description, the first evidence of the mammary apparatus was observed as a light streak at the twenty-fifth day of gestation. By the eighty-eighth day the cistern of the teat and gland was formed with some secondary sprouts. The

duct system develops during the balance of fetal life, and at birth the udder consists of a cistern and duct system which extends only a short distance into the fatty tissue of which the udder is composed. The duct system continues to grow after sexual maturity and the recurrence of oestrous cycles, but the formation of true alveoli was not apparent in nulliparous does. During the first half of gestation, proliferation of the lobule-alveolar system takes place, with an accumulation of secretion and enlargement of the lumina of the alveoli during the last half of gestation.

Preparation of avian sperm smears for microscopy, S. S. MUNRO (*Science, 83 (1936), No. 2161, pp. 532*).—Methods for fixing and staining the elongated heads of avian sperm with a minimum of distortion are described. The methods involve fixation in osmic acid vapor or instantaneous drying of thin smears.

Studies and investigations into the corpus luteum hormone, K. PORTMAN, trans. by A. ANDERSEN (*Acta Path. et Microbiol. Scand., Sup. 25 (1935), pp. 124, figs. 16; Dan. abs., pp. 118–121*).—The influence of corpus luteum hormone on the sexual cycle is reviewed, and the results of experiments dealing with the effect of corpus luteum extracts on gestation and parturition in the rabbit and its therapeutic use in cases of menorrhagia in humans are described.

Hormones in the urine following oophorectomy during pregnancy, H. ALLAN and E. C. DODDS (*Biochem. Jour., 29 (1935), No. 2, pp. 285–287*).—Bilateral oophorectomy in a woman in pregnancy had no influence on the anterior hypophyseal hormone content of the urine, but the oestrone content was definitely decreased.

Differences between anterior pituitary sex-stimulating hormones and pregnancy-urine substances as tested in the male mammal and bird, J. A. SCHOCKAERT (*Amer Jour. Physiol., 105 (1933), No. 3, pp. 497–507, fig. 1*).—Differences between the effects of pituitary extracts and pregnancy urine on the male genital system of rats, ducks, and chicks were studied. It was found that the weight of the testes of immature rats was increased both by pituitary extracts and pregnancy urine extracts. However, pregnancy urine extracts had no effect on the duck and chick, although pituitary extracts markedly increased the weight of the testes and comb development in the chick, with early spermatogenesis.

A study of theelin prepared from human and mare urine and from theelol, with some remarks on the preparation of theelin from mare urine, J. M. CURTIS, D. W. MACCORQUODALE, S. A. THAYER, and E. A. DOISY (*Jour. Biol. Chem., 107 (1934), No. 1, pp. 191–205*).—Theelin was isolated from the urine of pregnant mares by its insolubility in acid aqueous media and was found not to be significantly different from theelin isolated from human urine or theelol.

Histology of the ovary of hypophysectomized rats treated with urinary hebin, N. J. WADE (*Soc. Expt. Biol. and Med. Proc., 31 (1933), No. 3, pp. 321, 322*).—Hebin from pregnant urine administered to rats immediately after hypophysectomy failed to inhibit ovarian degeneration. The ovaries were converted into a lutein mass. Similar results were obtained when the administration of hebin following hypophysectomy was delayed.

Variation in plumage response of Brown Leghorn capons to oestrone, I, II, A. W. GREENWOOD and J. S. S. BLYTH (*Roy. Soc. [London], Proc., Ser. B., 118 (1935), No. 807, pp. 97–132, pls. 4, figs. 13*).—Two papers in this series are presented from the Institute of Animal Genetics, Edinburgh.

I. *Intramuscular injection.*—Feather responses, as a result of the administration of standardized intramuscular doses of oestrone to 87 Brown Leghorn capons ranging from 7.5 mo. to 5.5 yr. in age, were variable, some showing only an axial spot of red on the rachis, whereas others varied all the way up to a wide band stretching from one side of the feather to the other. Attempts to

correlate the variability with other conditions suggested the role of both genetic and physiological factors. Season and body weight did not show significant correlation, although the response increased with the age of the birds. Growth rate of the feathers was not a significant factor in determining the response.

II. *Intradermal injection.*—Intradermal injections of small doses of oestrone into 15 Brown Leghorn capons resulted in feather response in newly developing feathers growing in the area where the injections were made. The local nature of the response indicated that the replacement of black by red was a direct one The induced bars of red pigment were frequently unsymmetrical.

The pattern and symmetry of adult plumage units in relation to the order and locus of origin of the embryonic feather papillae, A. HOLMES (*Amer. Jour. Anat., 56 (1935), No. 3, pp. 513–537, pl. 1, figs. 6*).—A study of the origin of feather follicles showed that in the fowl the appearance of the feathers follows a definite order in each tract and in relation to other feather tracts.

Vitamin E and the gonads, W. SAPHIR (*Endocrinology, 20 (1936), No. 1, pp. 107, 108*).—Intraperitoneal injections of wheat germ oil had no influence in bringing about oestrum in castrated rats, increased activity of the ovaries, or stimulating luteinization. There was no evidence to suggest that vitamin E was of value in the treatment of primary sterility in the female.

Fundamental similarity in the development of gonadotropic response in the immature guinea pig and rat, S. C. FREED and A. COPPOCK (*Endocrinology, 20 (1936), No. 1, pp. 81–85, figs. 3*).—Administration of pregnancy urine extracts to immature rats and guinea pigs ranging in age up to maturity was found to have essentially the same effect on both kinds of animals except that the time intervals differed. The results are graphically expressed.

Occurrence of uniovular twins in multiple births, C. V. GREEN (*Science, 80 (1934), No. 2087, p. 616*).—In a back-cross generation involving the mouse species *Mus musculus*, with the recessive genes *d*, *b*, and *a*, and *M. bactrianus*, with the corresponding dominant allelomorphs *D*, *B*, and A^w, eight color combinations were expected (E. S. R., 68, p. 316). There was a significant excess of litter mates of the same sex and color among the progeny of the F_1 females, but the progeny of the F_1 males did not show this excess, this being accounted for as indicative of the occurrence of uniovular twins.

FIELD CROPS

Studies in experimental technique: The balanced block arrangement of treatments, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 40 (1936), No. 2, pp. 113–116, fig. 1*).—The method described, with application to a rate of nitrogen fertilization test with sugarcane, is said to reduce definitely the amount of border effect between treatments and to make allowance for any definitely natural "fertility slope" that may exist within the test area. Furthermore, the more accurate yield data secured from this arrangement are suitable to statistical interpretation by the analysis of variance.

[Field crops experiments in Alaska, 1934] (*Alaska Col. Sta. Bul. 4 [1935], pp. 8–10, 12, 13, 16–26, 37–41, 44–46, 48, 49, figs. 7*).—Agronomic studies (E. S. R., 73, p. 30), carried on at the station and Matanuska Substation and reviewed briefly, included variety trials with barley, wheat, oats, potatoes, forage legumes, timothy, and other pasture and lawn grasses; fertilizer tests with potatoes, bromegrass, hay, and wheat; crop rotations; and costs involved in growing vetch, field peas, oats, oats and vetch, and potatoes in a rotation scheme and in haymaking operations.

[Field crops experiments in Indiana] (*Indiana Sta. Rpt. 1935, pp. 14, 15–19, 58, 62, figs. 2*).—Agronomic studies (E. S. R., 73, p. 170), again reported

on briefly, dealt with top dressing wheat with soluble nitrogen in April; effects of legumes in the rotation and also of phosphorus and potash on yields of corn and wheat; variety tests with alfalfa; trials of Kobe lespedeza and *Lespedeza sericea;* time of planting tests with corn; studies of the quantitative amounts of carotenoid pigments in different varieties and strains of winter wheats; research on the granulation test of whole wheat meal; improvement of wheat in southwestern Indiana by premiums for quality, seed cleaning, and control of wild garlic; and effect of nutrition on the proportion of vitreous kernels in wheat.

[Farm crops experiments at the Moses Fell Annex Farm, Bedford, Ind.], H. J. REED and H. G. HALL (*Indiana Sta. Circ. 219 (1936), pp. 10–13, fig. 1*).—The average acre yields in variety trials with oats, winter wheat, rye, and barley, and soybeans for grain and hay, and average yields of spring barley, wheat, and rye are tabulated as heretofore (E. S. R., 72, p. 35), with brief accounts of the response of pasture to manure, lime, and fertilizer, and a comparison of clover, alfalfa, sweetclover, Korean lespedeza, and timothy in rotation with corn and wheat.

[Field crops research in Rhode Island] (*Rhode Island Sta. Rpt. [1935], pp. 6–8, 13–16*).—Brief reports are made on the progress of variety tests with potatoes, soybeans, and lawn and turf grasses; fertilizer experiments with potatoes, mangels, alfalfa, and lawn and turf grasses, including Kentucky bluegrass, and varieties and strains of bents; response of oats, timothy, and clover to different levels of soil reaction; comparison of steamed v. unsteamed composts and trials of nitrogen-supplemented composts for freedom of turf from weeds; residual effects of different levels of fertilizer; effects of crops on succeeding crops; crop rotation; control of lawn pests and weeds; and seed production of bentgrass varieties and strains.

[Field crops experiments in Tennessee], H. P. OGDEN, S. H. ESSARY, G. A. SHUEY, B. D. DRAIN, L. R. NEEL, B. P. HAZLEWOOD, and F. S. CHANCE (*Tennessee Sta. Rpt. 1934, pp. 7–9, 14, 15, 16, 22, 29, 32, 33, 34, 35–37, 38, 39*).—Progress results are reported from agronomic research at the station and substations (E. S. R., 73, p. 171), including breeding work with cotton, oats, barley, red clover, and winter peas; variety tests with cotton, wheat, rye, potatoes, sweetpotatoes, lespedeza, alfalfa, and tobacco; tests of Tennessee anthracnose-resistant clover grown in Western States for several years; cultural (including planting) experiments with cotton, rye, potatoes, and *Lespedeza sericea;* a cutting test with annual lespedeza; seed treatment tests with *L. sericea;* a trial of a corn-sorgo silage combination; sowing oats, barley, and rye and a grass mixture on bluegrass and Bermuda sod; comparison of winter cover crops; fertilizer trials, lint studies, and pollen germination tests with cotton; crop rotations; and pasture experiments. Several lines of work were in cooperation with the U. S. Department of Agriculture.

The genera of grasses of the United States, with special reference to the economic species, A. S. HITCHCOCK (*U. S. Dept. Agr. Bul. 772, rev. (1936), pp. 302, pls. 20, figs. 183*).—A revision by A. Chase of the bulletin noted earlier (E. S. R., 42, p. 828). See also a later note (E. S. R., 73, p. 465).

Native grass behavior as affected by periodic clipping, W. B. GREENER (*Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 447–456, fig. 1*).—In a special study within a virgin-grass clipping experiment at the Oklahoma Experiment Station, wherein variously clipped and fertilized plats were compared with pasture and roadside plats, clipping native grass more than twice a year did not return enough additional production in the fifth year to pay for the labor, and production declined as the number of clippings increased. The most air-dry hay was obtained from a plat clipped twice and manured 6 yr. before at the rate of

10 tons with 400 lb. of 20 percent phosphate per acre. The least top weight was secured from plats clipped 8, 9, and 10 times annually. The greatest root weight came from unmolested roadside grass and then from an untreated plat clipped 5 times a year, from one plat clipped twice a year but receiving manure and phosphorus, and from a check plat, while the least root weight came from plats clipped oftenest and which also produced the least top weight. The greatest root volume was obtained from plats with greatest root weight, and the lowest root volume was on the pastured area, on a check plat, on the manured plat, and on a plat clipped 10 times a year. The roadside, check, and nitrated plats and a manured plat produced the highest root weight-volume factor. The lower root weight-volume factors were obtained on those areas clipped more often.

The soil moisture was greatest on unclipped plats and greater in the various horizons on plats less frequently clipped. For the average of the 14 plats the 1- to 3-in. horizon contained the most soil moisture, the 12- to 15-in. horizon second, and the 6- to 9-in. horizon third in the sixth year. The lowest soil moisture in the upper horizon was found in the unclipped plats, in the second horizon in a plat receiving manure and phosphate, and in the third horizon in the most frequently clipped plats. Soil organic matter was greatest in the upper horizons and in a plat receiving manure and phosphate, in one of the plats receiving sodium nitrate, and in an unclipped plat. Low soil organic matter was not always found where expected and did not appear to be associated with the amount of live roots. If soil organic matter content is quite permanently residual, it must be the result of previous vegetative growth.

The pH was highest in the upper horizon on plats manured and phosphated, but clipped only twice a year. It was also high on unclipped, pastured, and roadside plats, but was highest in the lower (12- to 15-in.) horizon of plats clipped 5 times, one of which received manure and phosphate. The lower horizon produced the highest average pH readings. The lowest pH reading was found in the 6- to 9-in. soil horizon of a plat clipped 9 times annually, and other low pH readings were distributed through the various horizons.

The Longleat experiments, 1927–1931, A. W. Ling, W. R. Muir, and J. D. Nutt (*London and Bath: Mendip Press [1934], pp. 29, fig. 1*).—This is the result of a pasture grazing test extending over a 5-yr. period, the grazing returns being expressed in terms of cow days per acre.

Little difference was noted in returns from intensive rotational grazing and extensive grazing on unfertilized areas, while systematic applications of complete fertilizer under intensive grazing increased returns by 27 percent and 25 percent, respectively, over unfertilized areas intensively and extensively grazed. Nitrogenous fertilizer alone gave disappointing results, while phosphorus and potash application encouraged legumes on the sod but did not materially increase carrying capacity. Complete fertilizer increased the protein and mineral content of the herbage, particularly the phosphorus content. All treatments were ineffective unless accompanied by favorable temperature and rainfall.

Hays and haying methods for the Upper Peninsula, B. R. Churchill (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 211–217, figs. 3*).—Haymaking experiments and trials of hay mixtures at the Upper Peninsula Substation, 1929–35, showed that the length of time required for curing hay at Chatham was largely influenced by prevailing weather, moisture content at cutting, yield, and type of hay. At cutting, legumes contained more moisture than timothy, and the latter usually was ready to store sooner. The value of addition of timothy to legumes grown for hay as an aid to curing seemed questionable unless timothy predominates in the mixture. The importance of such mixture at Chatham is that timothy will grow on spots not occupied by legumes and thus

help to keep out weeds. Where satisfactory stands of legumes are obtained, addition of more than a small percentage (not over 10 percent) of timothy is considered wasteful, since inclusion of large amounts of timothy seed in the mixture was no assurance that timothy would predominate therein. Timothy when grown in such mixtures was darker green, leafier, and taller, and contained a higher percentage of protein than timothy grown alone. Swath-curing generally was the more rapid curing method, although legumes left in the swath too long lost a large percentage of their leaves and the quality of hay was poor. Partial curing in the swath until the hay was well wilted, followed by windrow-curing, resulted in better hay than from complete swath-curing. Seeds mixtures and curing suggestions are included.

Humidity control in large chambers by means of sulfuric acid solutions, F. J. ZINK and C. O. GRANDFIELD (*Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 463–466, figs. 2*).—The humidity control cabinets described were used at the Kansas Experiment Station in connection with studies on the influence of atmospheric humidity on the rate of drying of alfalfa and the effect of humidity on the seed setting of alfalfa plants, conducted in cooperation with the U. S. Department of Agriculture.

Ladino clover for western Oregon, H. A. SCHOTH (*Oregon Sta. Circ. 117 (1936), pp. 8, figs. 2*).—Practical information, based on experiments and observations in cooperation with the U. S. D. A. Bureau of Plant Industry, is given on the characteristics and climatic and soil needs of Ladino clover (*Trifolium repens latum*), seedbed preparation and planting practices, and on handling the crop for pasture, hay, and seed.

Corn planting and cultivation, compiled by C. F. CLARK (*Mississippi Sta. Bul. 312 (1936), pp. 25*).—Information compiled from reports of experiments made by State experiment stations and the U. S. Department of Agriculture covers date and method of planting, seedbed preparation, methods of cultivation and their effects on yield, topping corn, and pulling fodder.

Corn varieties for silage in Rhode Island, T. E. ODLAND and H. C. KNOBLAUCH (*Rhode Island Sta. Bul. 257 (1936), pp. 14, figs. 2*).—Variety tests with silage corn, 1931–34, comparing a late, three medium, and four early corns, showed the late Eureka to average the most green material, 21.17 tons per acre, and the most dry matter, 7,907 lb., while West Branch Sweepstakes, a medium dent, surpassed Eureka in yield of protein, 446 lb., and total nutrients, 5,405 lb. The very early varieties were found to yield too low for silage purposes. For the average dairyman of the State who wants as much feeding value per acre as possible without handling excessive water in green material, the choice of a medium-maturing variety as West Branch Sweepstakes seems advisable. Where the season is longer a later type may be used. In general, a variety that will reach the dough stage in the average season appears most desirable for silage purposes.

Hybrid corn, A. N. HUME and C. J. FRANZKE (*South Dakota Sta. Bul. 299 (1936), pp. 28, figs. 12*).—A popular discussion of inheritance in corn, with special emphasis on the effects of inbreeding and hybridization, is presented, together with the comparative yields of several hybrids and varieties of corn at the station, 1931–35, and yields and stands of a number of hybrids and varieties at Beresford in 1935. Records of the annual rainfall by months at the station, Centerville, Highmore, Eureka, Cottonwood, and Vivian are appended (pp. 22–28).

Michigan hybrid No. 561 a borer-resistant field corn, A. R. MARSTON (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 223–225, figs. 2*).—Hybrid No. 561, a uniform, vigorous, productive dent corn, exhibiting resistance to Euro-

pean corn borer and said to be suited only for the southern part of Michigan, is described as a top cross between S–10 (a synthetic variety made by blending 91 inbreds) and an inbred strain. All the inbreds involved have Maize Amargo breeding (E. S. R., 69, p. 513) and have shown strong indications of resistance to borer attack.

Hail damage to corn, J. C. ELDREDGE (*Iowa Sta. Bul. 348 (1936), pp. 303–322, figs. 7*).—This is a popular abridgment of certain phases of Research Bulletin 185 (E. S. R., 73, p. 775).

The effect of variety, planting date, spacing, and seed treatment on cotton yields and stands, G. A. HALE (*Jour. Amer. Soc. Agron., 28 (1936), No. 5, pp. 364–369*).—The average results (1930–34) of a multiple-factor field experiment at the Georgia Experiment Station, including five cotton varieties and several planting dates and spacings and a seed treatment, are reported. This type of experiment was found to have a number of advantages over the common single variable field experiments.

Half and Half and Stoneville 2 led in yields when all planting dates were averaged. The differences in varietal response to the different planting dates indicate that the date of planting of varietal experiments may markedly affect the relative yields of the varieties and the value of the results for making varietal recommendations. The varieties showed some significant differences in ability to produce satisfactory stands, especially when planted early or during late March. The early (late March) planting and the medium (late April) planting produced the same 5-yr. average annual yields of lint, while the late (late May) cotton yielded only about one-half as much lint. Stands were poorest on the earlier planted cotton and thickest in May plantings.

When Stoneville 2 was grown, 1932–34, in 3.5-ft. rows, unthinned in 1-ft. and 3-ft. hills, and thinned to two plants in hills 1 ft. apart, the last spacing produced the highest yields, except for the medium planting date, when unthinned cotton in 1-ft. hills equaled thinned cotton spaced 1 ft. apart. The unthinned cotton was relatively poorer when planted late than for the other dates. Number of hills or the distribution of the plants rather than the total plants per acre is most important in spacing experiments. Planting date may affect the ratings of different spacings in cotton spacing experiments.

Where the cotton was planted early, although stands were somewhat irregular in some seasons, there was no significant correlation between acre yield and the total plants per acre and only a slightly significant correlation between yield and number of hills per acre. Similar results were had for late planted cotton with good stands every year. The medium planting showed a highly significant, positive correlation between lint yield and both number of plants and hills per acre. The number of hills on the variety plats, like those on the spacing plats, was correlated more closely and positively with the pounds of lint cotton produced than with the number of plants per acre.

Treating the Stoneville 2 cottonseed with an organic mercury compound had no significant effects on stands or yields.

Part I, Report on gins in Louisiana and the proper ginning of cotton, G. A. GERDES. **Part II, Introduction and summary of U. S. Department of Agriculture Technical Bulletin No. 503 entitled "Effects of Gin-Saw Speed and Seed-Roll Density on Quality of Cotton Lint and Operation of Gin Stands",** C. A. BENNETT and F. L. GERDES (*Louisiana Sta. Circ. 16 (1936), p. 7*).—The first part of this report presents a summary of experience on gin operation in Louisiana; the second part summarizes a publication previously noted (E. S. R., 75, p. 117).

Flax: Experimental studies in growing, decorticating, chemical degumming, and manufacturing into yarns and papers, H. H. WILLIS (*Washington:*

Textile Found., [*1936*], *pp. 32, figs. 6*).—Findings in fiber flax experiments, 1934–35, are presented in brief reports entitled Growing of Flax (Crops of 1934 and 1935), by L. H. Dewey (pp. 6–11); Mechanical and Chemical Processing of Flax by the New Method (pp. 12–19) and Spinning of Flax Fiber (Crop of 1934) (pp. 20–30), both by H. H. Willis; and Possible Use of American Flax in the Paper Industry, by W. E. Emley and H. U. Kiely (pp. 31, 32).

Fiber flax in Oregon, B. B. ROBINSON (*Oregon Sta. Circ. 118 (1936), pp. 12, figs. 2*).—Certain practices found most successful in fiber flax production under Willamette Valley conditions are outlined on the basis of experience and research in cooperation with the U. S. D. A. Bureau of Plant Industry. The information covers the flax contract, distribution, climatic and soil adaptation, rotations, fertility needs, seedbed preparation and planting, and curing and harvesting the crop, and flax mill operations which have some bearing on production problems.

Effect of planting date on rate of sprout emergence and multiple sprouting of tubers of the Jerusalem artichoke, C. E. STEINBAUER (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 617–621*).—Time of planting tests, 1931–33, with several varieties of Jerusalem-artichokes revealed that delay in planting (up to about May 15) resulted in fewer days for sprout emergence from the soil, more stems per seed piece, general reduction in weight of tops, reduced yields (after May 1), and fewer tubers in plantings after April 15. The loss of dominance observed with delayed planting appeared from these results to be similar in the Jerusalem-artichoke and the potato.

Cultural and storage research with potatoes, E. V. HARDENBERG (*Amer. Potato Jour., 13 (1936), No. 2, pp. 38–44*).—This review, a contribution from Cornell University, deals with ecological and seed studies and variety, cultural, and storage tests, and lists 29 titles.

Potato nutrition and soil fertility studies in 1935, O. SMITH (*Amer. Potato Jour., 13 (1936), No. 2, pp. 44–52*).—Summarizing the work on mineral nutrition, fertilization, and soil fertility, as applying to the potato, this report lists 50 titles.

Influence of fertilizers on maturity and type of potatoes, F. M. HARRINGTON (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 560–562*).—Phosphorus applications in growing Russet Burbank potatoes, as shown by Montana Experiment Station tests, have resulted in better maturity and handling qualities, better netting, improvement in type, and an increase in percentage of better shaped potatoes, resulting in heavier yields of No. 1 potatoes. Nitrogen and also potassium delayed maturity, and these two elements either alone or in combination had other effects which are discussd briefly.

Influence of fertilizer on potato maturity and type, F. M. HARRINGTON (*Amer. Potato Jour., 13 (1936), No. 8, pp. 218–220*).—Essentially noted above.

Effect of soil reaction on yield and market quality of potatoes, O. SMITH and G. C. MOORE (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 563–565*).—The response of Smooth Rural potatoes to a range of soil reactions in percentage of scabby tubers is reported for the period 1932–35, supplementing information given in an earlier note (E. S. R., 71, p. 624).

Non-legumes as green manures for potatoes, J. BUSHNELL (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 566–568*).—Potato yields in ordinary farm rotations on the silt loam at the Ohio Experiment Station were not satisfactory with chemical fertilizers alone. The somewhat better yields where manure was applied seemed due in part to an increased aeration of the soil, for similar benefits were obtained by addition of sand to the soil (E. S. R., 73, p. 470). Corn as a green manure (E. S. R., 71, p. 768) provided more organic matter to plow under and resulted in larger potato yields than have soybeans or sweetclover.

No serious practical problems arose from the nitrogen deficiency resulting from turning under much low-nitrogen organic matter nor were they encountered in either plowing or disking down corn. The nitrogen requirements of the potatoes were met by including from 40 to 80 lb. of nitrogen per acre in the regular potato fertilizer.

Experiments with potatoes on muck soil, J. BUSHNELL (*Ohio Sta. Bul. 570 (1936), pp. 25, figs. 7*).—Variety, planting date, fertilizer, depth of planting and control of *Rhizoctonia*, spacing, irrigation, and spraying experiments carried on in 1932–35 at the Muck Crops Experiment Farm near McGuffey in Hardin County are reported, with comments on frost prevention and recovery and the possibility of producing seed potatoes on muck.

Muck appeared to be the best soil in Ohio for potatoes, yields at the experiment farm exceeding those on farms located on Wooster silt loam or Chenango fine sandy loam. However, frosts may be serious on muck soils.

Irish Cobbler gave good yields from May 20 to 25 plantings, and earlier plantings gave higher yields in the two seasons free from June frosts. Russet Rural and White Rural matured about 2 weeks later than Irish Cobbler, and since early frosts had not occurred at the farm, equaled or surpassed Irish Cobbler in yield. The Rurals tend to develop growth cracks in seasons that favor rapid growth. In 2 of 3 yr. Irish Cobblers from the experiment farm were very satisfactory for seed for the early crop in southern Ohio.

Potash was the only fertilizer constituent that gave large yield increases. Results to date suggest potash fertilizer alone to supply 270 lb. of potash per acre, or 750 lb. of an 0–9–36 mixture. Highest yields resulted from a planting depth of 3 in. At that depth, and with shallow covering at planting, *Rhizoctonia* did not appreciably reduce the stand when the seed was relatively free from *Rhizoctonia* or when infected seed was treated properly. Spraying at weekly intervals during the period of rapid growth has been advisable for controlling leafhoppers and flea beetles. Both overhead and subirrigation increased yields, subirrigation seeming practicable on a field scale.

The Katahdin potato in Michigan, H. C. MOORE and E. J. WHEELER (*Michigan Sta. Spec. Bul. 271 (1936), pp. 15, fig. 1*).—The characteristics; yields; soil, cultural, fertility, harvesting, storage, and insect and plant disease control requirements; and market value and culinary quality of the Katahdin potato (E. S. R., 73, p. 471; 74, p. 630) are described from various tests in Michigan, 1931–35. Special cultural recommendations based on this work are outlined.

Katahdin proved well adapted to most sections of Michigan, producing table stock of good market quality, and developing tubers of good type under hot, dry conditions which often prove unfavorable to Russet Rural. Katahdin responded favorably to early planting, irrigation, fertilization, and close spacing, often outyielding Russet Rural in tubers of good type. When planted in April or May for the August and September market it generally surpassed Irish Cobbler in yield of marketable potatoes.

Katahdin is described as resistant to mild mosaic, but susceptible to leaf roll, spindle tuber, and other diseases commonly found in Michigan potatoes. It is more susceptible to scab than Russet Rural and is often injured more than the Rural varieties by leafhoppers and flea beetles.

Toxicity from arsenic compounds to rice on flooded soils, J. F. REED and M. B. STURGIS (*Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 432–436*).—The effect on the yield of rice of applications of varying amounts of calcium arsenate on different soil types was studied at the Louisiana Experiment Station, where it was found that the toxic effect was governed largely by the soil type. On the lighter soils rice was seriously affected by 50 lb. per acre of calcium arsenate, while on the heavier soils 150 lb. was not injurious. No correlation

was found between water-soluble arsenic and toxicity, though a relationship existed between 0.05N HCl-soluble arsenic and toxicity. Less total arsenic was found in the soil at the conclusion of the test than was present at the beginning. From an analysis of the rice panicles and straw, the loss could not be attributed to crop removal. Since the soil was in a highly reducing condition when flooded under cultivation, the loss in arsenic content might be accounted for by complete reduction to gaseous arsine. Furthermore, indications were that it is the reduced arsenic compounds, arsenites, etc., that are particularly toxic to rice under flooded conditions.

Relation of phosphorus to growth, nodulation, and composition of soybeans, T. B. HUTCHINGS (*Missouri Sta. Res. Bul. 243 (1936), pp. 46, figs. 20*).—The influence of phosphorus on the growth, nodulation, and composition of Virginia soybeans was studied by using colloidal clay, employed earlier by Albrecht (E. S. R., 70, p. 174) and Horner (E. S. R., 75, p. 42), as a carrier for this anion together with cations as plant nutrients.

Phosphorus did not appear to be a significant factor in controlling nodulation in the early activity of the plant. As indicated by growth and plant composition, seed phosphorus and applied phosphorus were used most efficiently in the early growth period when the calcium needs of the plants were satisfied. When plenty of calcium was supplied the crop contained more of the other nutrients as well as of the calcium as a result of increased production and usually as a consequence of an actual tissue enrichment as measured by percentage. The phosphorus and nitrogen content of the plant material were closely related. No mathematically specific ratio was found for calcium and phosphorus, although it was suggested. A relatively close interrelationship of calcium-phosphorus-nitrogen and their importance in the successful growing of soybeans and possibly other legumes was evident. As measured by consecutive crop production, phosphorus additions represented a higher level of fertility.

The colloidal fraction of the Putnam silt loam was shown to adsorb phosphorus, this adsorption being influenced by adsorbed calcium. The phosphorus so adsorbed is released readily by electrodialysis and is available for plants on the basis of such a measure.

Kingwa soybeans, R. J. GARBER (*West Virginia Sta. Bul. 273 (1936), pp. 4; also in Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 457–459*).—Because of similarity in origin, yields, and other agronomic characters, and the currently much wider distribution and commercial establishment of Kingwa soybeans, it is proposed that Pekwa soybeans (E. S. R., 66, p. 735), also a pure line selection made at the station from the Peking variety, be renamed Kingwa.

Effect of tillers on the development of grain sorghums, A. T. BARTEL, J. H. MARTIN, and R. S. HAWKINS (*Jour. Amer. Soc. Agron., 27 (1935), No. 9, pp. 707–714, figs. 4*).—Tillers and leaves of the main stalks of Dwarf hegari were removed at several developmental stages in a cooperative study by the Arizona Experiment Station and the U. S. D. A. Bureau of Plant Industry.

The tillers increased the development of the main stalks when main stalk leaves were removed before heading, and the weights of the main stalk increased the longer the tillers were left on the plant. When the main stalk was defoliated at the soft dough stage of the kernels or when the main stalk leaves were allowed to remain, the weights of the main stalk decreased the longer the tillers were left on the plants. Tillers in such cases seemed detrimental to main stalk development, although they produced more than enough grain and stover to offset decreased growth of the main stalk. Evidently plant juices are free to move from the main stalk to the tillers, or the reverse, depending upon when the nutritional deficiency occurs. A vascular connection between the main stalk

and tillers is illustrated. The effects of the tillers on the main stalks of plants subjected to drought were about the same as plants receiving ordinary irrigation.

Longevity and viability of sorghum seed, R. E. KARPER and D. L. JONES (*Jour. Amer. Soc. Agron., 28 (1936), No. 4, pp. 330, 331, fig. 1*).—Additional germination tests (E. S. R., 59, p. 629) by the Texas Experiment Station on seed stored under rather dry conditions at Lubbock showed the germination percentage of Blackhull kafir to be in 1917, 100; 1924, 88; 1926, 79.5; 1927, 65; 1929, 48; 1931, 34.2; 1933, 15.5; 1935, 4; and 1936, 0.5. Decline in vigor of germination compared with fresh seed was evident in tests after 1931.

Cane growth studies: The dominating effect of climate, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 40 (1936), No. 2, pp. 143–156, figs. 5*).—In a 14-mo. study supplementing that of Das (E. S. R., 73, p. 40), the H 109, Striped Tip, and P. O. J. 2878 sugarcane varieties were grown at Makiki (40-ft. elevation) and Manoa (550 ft.) on both the yellowish brown silty loam of Manoa and the finer chocolate brown loam of Makiki under several fertilizer treatments.

Under the more favorable Makiki climate more than three times as much sugar was produced as at Manoa. H 109 took best advantage of the favorable Makiki conditions, while Striped Tip did best at Manoa. Relatively 19 percent more phosphate and 50 percent more potash were found per unit of juice in the cane grown at Manoa. The soils of the series grown at Manoa became generally more acid than the Makiki series while the crops were growing in them. The relative cane yields from the Manoa soil averaged 24 percent more than the Makiki soil, being 40 percent higher at Makiki and only 8 percent over the Makiki soil at Manoa. The Manoa soil also netted considerably more sugar when the cane was grown thereon at Makiki. H 109 was superior to P. O. J. 2878 and Striped Tip at both Makiki and Manoa, and yet it apparently was a more economical user of both phosphate and potash. P. O. J. 2878 surpassed Striped Tip at Makiki, but the reverse occurred at Manoa. P. O. J. 2878 took up less phosphate but more potash than Striped Tip. P. O. J. 2878 when amply supplied with fertilizer on either soil type gained in yield of cane and sugar over the inadequately fertilized series, such gains being much greater at Makiki. The heavier fertilization affected adversely the quality of P. O. J. 2878 grown at Manoa but not at Makiki.

Sugar cane variety report, season of 1935, C. B. GOUAUX and E. C. SIMON (*Louisiana Sta. Bul. 274 (1936), pp. 26*).—The tabulated results of continued varietal comparisons (E. S. R., 71, p. 628) in 10 localities in the sugarcane belt, reported by Gouaux, show the cane yields and sucrose content (and for 1 field, sirup production), relative values per ton and acre for plant cane and first and second stubbles of a number of sugarcane varieties grown on Yazoo sandy soil, Yahola very fine sandy loam, Iberia clay loam, Sharkey loam, and Lintonia and Olivier silt loams. Results of fall plant cane and first stubble tests of all test fields indicate that C. P. 28–19 had given the highest sucrose tests, with C. P. 29–320, P. O. J. 234, Co. 281, and C. P. 28–11 following in order. The recently released C. P. 28–11, C. P. 28–19, and C. P. 29–320 varieties mature early and under favorable conditions can produce good field yields as plant cane and stubble. C. P. 28–19 and C. P. 29–320 are good land canes, and C. P. 28–11 is well suited to black lands. C. P. 28–11 is very susceptible to cane borers and windstorm damages, but resists stubble deterioration, red rot, and mosaic diseases, and can replace C. P. 807 on the heavier poorly drained soils. On very fertile soils C. P. 28–19 will lodge, while C. P. 29–320 is very erect growing and not subject to lodging. Both C. P. 28–19 and C. P. 29–320, like Co. 281, respond well to good cultivation. Certain features of Co. 281 and 290 also are discussed.

In tests at the sugar experiment station, reported by Simon, fiber contents ranged from 10 percent for Co. 290 to 15 for C. P. 28–11. Maturity studies continued to show that C. P. 28–19 and C. P. 29–320 are very early maturing canes. At Baton Rouge, C. P. 29–320 consistently matured much earlier than P. O. J. 234, while C. P. 28–19 was as early. In the 1935 series, both C. P. 28–19 and C. P. 29–320 were earlier in maturity and their juices contained higher sucrose than P. O. J. 234. Co. 281 again showed itself to be somewhat late in maturity. In a comparison of commercial varieties, P. O. J. 234 was definitely inferior to the newer commercial varieties. The sugar-per-acre yields of second-year stubbles of Co. 281, C. P. 28–11, C. P. 28–19, and Co. 290 were greater than from plant cane of P. O. J. 234. The excellent stubbling qualities of the newer varieties were quite evident. Findings in a windrowing experiment in which Co. 281, the standard windrowing variety, was outstanding, confirmed previous work to the effect that sufficient acreage of sugarcane which will stand windrowing must be grown if the grinding season is to be prolonged with safety after December 20.

A field aspirator for emasculating sweet clover flowers, D. A. SAVAGE (*Jour. Amer. Soc. Agron., 27 (1935), No. 9, pp. 774, 775, fig. 1*).—Although the method by Kirk (E. S. R., 62, p. 513) for emasculating sweetclover flowers was used successfully in the greenhouse at the Fort Hays, Kans., Substation, it is not considered suited for field use where water is not available. Therefore, the simple and efficient aspirator described, which provides suction without the use of water, was developed. Satisfactory results were obtained also from its use in breeding alfalfa.

Sweet potato varieties and cultural practices, compiled by C. F. CLARK (*Mississippi Sta. Bul. 313 (1936), pp. 27*).—The information presented on the yields, characteristics, and storage behavior of sweetpotato varieties; consumer preferences; bedding; home-grown v. shipped-in plants; northern- v. southern-grown seed; comparative yields of vines, draws, and whole roots; seedbed preparation; time of planting; spacing; use of vines and vine parts as plants; and effect of cutting off vines on yields was compiled from reports of experiments and studies made by State experiment stations and the U. S. Department of Agriculture.

Studies on Hessian fly infestation and some characters of the wheat culm, D. C. ANDERSON and H. M. BROWN (*Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 479–483, fig. 1*).—Strain determinations on percentage of Hessian fly infestation and field lodging, and culm determinations on breaking strength, weight, and diameter were made at the Michigan Experiment Station on 111 strains of soft winter wheat in 1932 and 112 strains in 1933.

Significant interstrain differences were noted in fly infestation, breaking strength, weight of culm, and diameter of culm, and these differences, according to interannual correlations, tended to persist from year to year. There were significant differences in breaking strength, weight, and diameter of culm between the puparia-free and puparia-infested groups within the same strain, but the very low nonsignificant coefficients of correlation between fly infestation and breaking strength, weight, and diameter of culm indicate that selection for fly resistance by using one of these morphological factors would be ineffective. Hessian fly infestation and field lodging were associated significantly and positively.

Canawa—a new variety of soft red winter wheat, R. J. GARBER and L. S. BENNETT (*West Virginia Sta. Bul. 272 (1936), pp. 8, fig. 1*).—Originated from a single head selected from a mixed variety grown at the station in 1921 under the name of Canada Hybrid, Canawa is a smooth, soft red winter wheat with

medium-sized spikes that droop when the grain is ripe and with purplish, stiff straw showing little tendency to lodge. The kernels are relatively hard for a wheat belonging to the soft red winter class. Experimental tests show the yielding ability of Canawa to equal that of Fulhio, a productive wheat under West Virginia conditions. In cooperative tests with farmers, Canawa produced significantly greater average yields than did the wheat now commonly grown.

Tes s made by the Grain Division of the U. S. D. A. Bureau of Agricultural Economics indicated that Canawa has satisfactory milling qualities, and that while flour from Canawa probably is more suitable for pastries and biscuits, it may be expected to give satisfactory results when used for bread, particularly if blended with stronger flours.

Varietal composition of Canadian hard red spring wheat, J. G. C. FRASER and A. G. O. WHITESIDE (*Sci. Agr., 16 (1936), No. 8, pp. 409–423, figs. 4; Fr. abs., p. 423*).—Varietal analyses of the minimum Standard and Export Standard samples of the Western Grain Inspection Division, Winnipeg, covering 1926 to 1934, and of samples from cargo shipments from 1928 to 1934, inclusive, showed Marquis to be the predominating variety found in contract grades Manitoba 1, 2, and 3 Northern, the only grades considered. After 1929, varieties classed as fair to poor quality wheats decreased rapidly. The varietal analyses for the cargo shipments did not agree with the varietal analyses for the standards, especially for the Manitoba 2 and 3 Northern grades. This is explained chiefly by the fact that Standard samples are made up early in the crop year, while cargo samples were secured over a longer period and therefore included more wheat grown in the northern districts where Garnet is the chief variety. Protein determinations made on the cargo samples for 1932–34 indicated that the Atlantic and Pacific shipments for the Manitoba 1 Northern grade averaged about the same, although considerable variation occurred between different cargo samples. For the Manitoba 2 and 3 Northern grades the Pacific shipments averaged substantially below the Atlantic samples.

The wheat meal fermentation time test for measuring quality in wheat, G. H. CUTLER and W. W. WORZELLA (*Indiana Sta. Circ. 218 (1936), pp. 14, figs. 11*).—In the wheat meal fermentation test a given quantity of whole wheat meal is mixed with a definite amount of yeast suspension and made into a doughball. The latter is then placed in a beaker, containing distilled water, which is put into an oven in which the temperature is favorable for yeast fermentation, gas evolution, and disintegration of the dough mass. The length of time or fermentation time required to start the disintegration of the doughball is used as an index or measure of the gluten strength of flour which may be derived from a given sample of wheat. The method is described in detail and essential features are illustrated, with remarks on i's limitations and interpretations and on the need for milling and baking tests in addition for the securing of complete data on quality. A classification of wheats based on utility and quality is suggested.

Yams for Hawaiian gardens, E. L. CAUM and J. P. MARTIN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 40 (1936), No. 2, pp. 171–182, figs. 16*).—The behavior of the Spiny or Lesser yam, *Dioscorea esculenta*, in tests in Hawaii is described and illustrated, with notes on other yams found in Honolulu markets.

Length of the dormant period in cereal seeds, A. H. LARSON, R. B. HARVEY, and J. LARSON (*Jour. Agr. Res. [U. S.], 52 (1936), No. 11, pp. 811–836*).—When the length of the rest period of a number of common varieties of wheat, oats, barley, and rye was determined by germination tests at the Minnesota Experi-

ment Station, made on material collected at the soft dough, hard dough, and ripe stages of maturity, the rest period was found to be longest in immature seeds. Lowering the temperature at which the seed was stored generally prolonged the rest period. The length of the rest period was found to vary greatly with the variety. In general, winter wheats had a shorter rest period than spring wheats. In oats, a rest period of any considerable length was found only in the late varieties.

An interesting seed combination, T. R. STANTON and E. G. BOERNER (*Jour. Amer. Soc. Agron., 28 (1936), No. 4, pp. 329, 330, fig. 1*).—Oats having seed of Napa thistle (or any other noxious weed) lodged on the palea behind the folds of the lemma of primary grains, as in the material described, evidently should not be used for seed, since such weed seeds cannot be removed mechanically.

Effectiveness of furfural petroleum combinations in eradicating certain noxious weeds, H. L. BUCKARDT (*Jour. Amer. Soc. Agron., 28 (1936), No. 6, pp. 437–442, fig. 1*).—About 70 percent of the dandelion plants growing on plats where the grass was kept cut short were killed by one application of 4 cc of the best furfural petroleum materials in a study at the Illinois Experiment Station. More material was required to kill large mature plants than small plants. Some plants killed 3 in. below the crown produced new growth, appearing above ground 42 days after treatment.

Kills of 100 percent were obtained when broadleaved or buckhorn plantain plants were treated with 4 cc of the best materials. One application of 250, 500, or 750 gal. per acre of any of the materials did not kill all the roots of either quackgrass or field bindweed, nor did a second application on the same plats with the same quantity as applied the first time give complete eradication. Late June and July treatments gave a higher percentage of kill than late August and September treatments, moisture being one of the most important factors. The resulting percentage of kill was not related to the time of day when application was made. When added to petroleum oils, furfural increased their toxicity, causing them to kill with greater rapidity. The lighter grade petroleum oils were in all cases more toxic than heavier grade oils.

Leafy spurge, Euphorbia esula L., A. L. BAKKE (*Iowa Sta. Res. Bul. 198 (1936), pp. 207–246, figs. 23*).—The characteristics, distribution, and taxonomic relationships of leafy spurge, its flowering and fruiting habits, pollination, seed studies, and certain characteristics of the root system, leaf, stem, and latex system are described from research in progress at the field weed laboratory, near Hawarden.

Leafy spurge is a perennial weed common in northwestern Iowa and in Delaware County in northeastern Iowa, where it causes serious damage to crops. It is also common in other countries. Heavy infestations also exist in eastern South Dakota, eastern North Dakota, and southwestern Minnesota. The leafy spurge occurring in Iowa is *E. esula* rather than *E. virgata*.

The fruit is a capsule containing three ovules and bursting on maturity, forcibly ejecting the seed, which scatter to some distance. The flowers are pollinated chiefly by insects, as the stamens mature after the pistil. The soldier beetle (*Chauliognathus pennsylvanicus* De Gur.) is commonly found upon the flowers.

Fully mature seeds are brown and are heavier and absorb water faster than the gray, immature seeds. The seeds float on water and germinate readily, best between 82° and 88° F., where imbibition is greatest. Germination did not occur between 34° and 37°. Seeds placed in solutions of calcium salts absorbed more water than those in solutions of sodium salts. Seeds placed in solutions of sodium chlorate (0.10 M) failed to germinate. Those taken from plants

sprayed with sodium chlorate 1 lb. to a gallon of water and then dried produced a germination of 3 percent. While *E. esula* seeds are found in large numbers in the digestive tracts of mourning doves of the region, no whole or viable seeds were found in the intestines, indicating that this bird is not an agent in distributing the weed.

The root system of leafy spurge may penetrate vertically more than 15 ft. Shoot buds were found to a depth of 10 ft. It is assumed that the age of a plant may be determined by the rings of differential growth in the roots. Leafy spurge has an extensive food storage system in the roots. Roots taken from plants sprayed with sodium chlorate and from plants on fallowed areas showed a small amount of food storage.

The leaves of leafy spurge possess typical xerophytic characters, the stomata are sunken into pits or cavities, and there are two layers of palisade parenchyma cells. The plant is provided with a well-developed latex system.

Quack grass control, C. R. MEGEE (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 219–223*).—Practical information is given on the control of quackgrass in infested fields by double plowing, summer fallow, summer plowing, and by special quackgrass cultivators and control of patches by spraying or dusting with chlorates.

HORTICULTURE

[Horticultural studies by the Alaska Station] (*Alaska Col. Sta. Bul. 4 [1935], pp. 11, 12, 14, 15, 46–48, figs. 2*).—Brief reports are presented on the results of cultural experiments with blueberries, currants, and raspberries; on variety and breeding trials with garden peas; and on tests at the Matanuska Substation of various small fruits, crab apples, rhubarb, horseradish, and ornamentals.

[Horticultural studies by the Indiana Station] (*Indiana Sta. Rpt. 1935, pp. 44–47, 48–50, 55, 57, 58, figs. 7*).—Included in this report are the results of studies of orchard soil management, apple pruning, spray materials, stationary v. portable sprayers, the removal of spray residues, apple storage, plum varieties, pyrethrum production, tomato seed production, factors influencing tomato and muskmelon quality, photoperiod and light intensity requirements of greenhouse plants, the marketing of vegetables and strawberries, seasonal changes in the composition of Stayman Winesap apple trees, the influence of spray schedules and washing treatments on residues, effect of cultural treatments on growth and reproduction of apple trees, varieties of pumpkins, and factors affecting the canning qualities of pumpkins.

[Horticultural work at the Moses Fell Annex Farm], H. J. REED and H. G. HALL (*Indiana Sta. Circ. 219 (1936), pp. 13–16, fig. 1*).—Brief comments are presented on the results of variety tests with plums, control of codling moth, removal of spray residues from apples, comparative costs of stationary and portable spraying, and the storage of apples.

[Horticultural studies by the Puerto Rico Station] (*Puerto Rico Sta. Rpt. 1935, pp. 13–23, 27–29, figs. 7*).—Among studies the progress of which is discussed are the breeding of sweet corn adapted to tropical conditions; the transportation of sweet corn to New York City; culture, improvement, and utilization of bamboo; effect of shading on coffee; comparative yields of Columnaris and Puerto Rican varieties of Arabian coffee; resistance of the Columnaris coffee to root rot (*Rosellinia bunodes*); and culture of the mangosteen, palm chestnut, *Uvaria lancifolia*, and of the wax flower (*Phaeomeria speciosa*).

[Horticultural studies by the Rhode Island Station] (*Rhode Island Sta. Rpt. [1935], pp. 9–12, 16–18, 20–23, 24, 25*).—Included are brief comments on the progress of experiments in the fertilizer requirements of vegetables; strain and

variety tests of vegetables; breeding of blackberries; fertilizer needs of raspberries and grapes; variety tests of drupe fruits, with special reference to brown rot resistance in plums; value of Burgundy mixture for the control of brown rot; winter forcing of gladioluses, rhododendrons, azaleas, and other ornamentals; optimum levels of soil nitrates in the growth of carrots; fertilizers for *Daphne cneorum* and *Sciodopitys verticillata;* the response of *D. cneorum* to different soils; and the effect of day length on the nitrogen requirements of beets.

[Horticultural studies by the Tennessee Station], B. D. DRAIN and B. P. HAZLEWOOD (*Tennessee Sta. Rpt. 1934, pp. 27, 28, 29, 32, 33, 37, 38*).—Among studies discussed are the breeding of red raspberries and strawberries; testing of strawberry varieties; comparison of mazzard and mahaleb rootstocks; value of the Methley plum, improvement of pyrethrum, testing of varieties of sweet corn, and tests of ornamentals.

Work at the Mericourt Substation included tests of new strains of pyrethrum, culture of red raspberries, value of calcium cyanamide for asparagus, and the response of crapemyrtle and mountain-laurel to lime.

At the West Tennessee Substation there were conducted variety tests with vegetables and various fruits.

Delta home vegetable gardens, E. A. CURREY (*Mississippi Sta. Bul. 311 (1936), pp. 22, figs. 12*).—General information is presented on cultural requirements, comparative yields, control of various insect and fungus pests, etc.

The influence of acid-neutral fertilizers on vegetable crop production in eastern Virginia, J. B. HESTER and F. A. SHELTON (*Virginia Truck Sta. Bul. 90 (1936), pp. 1289–1301, figs. 5*).—In pot experiments in which sorghum, spinach, and collards were grown on a Sassafras loam soil fertilized with acid- and nonacid-forming materials, it was observed that the soil reaction in the fertilizer zone may be materially influenced by the type of material applied. Dolomitic limestones of 80- to 100-mesh fineness were found capable of approximately maintaining the soil reaction against changes due to acid-forming salts, such as sulfate of ammonia. Nonacid-forming fertilizer greatly increased the yield of soil acid sensitive crops. The authors point out that limestone in the fertilizer does not replace lime applied to correct soil reaction but does tend to reduce the frequency with which subsequent applications may be required. Certain soils may actually benefit from the application of acid fertilizers.

Magnesium deficiency.—I, The value of magnesium compounds in vegetable production in Virginia, R. L. CAROLUS and B. E. BROWN (*Virginia Truck Sta. Bul. 89 (1935), pp. 1247–1288, figs. 11*).—Discussing the role of magnesium in the development of chlorophyll, the natural distribution of magnesium in the soil, and reasons for its deficiency in eastern Virginia, the authors report the results of 5 years' studies with most of the important truck crops to determine their response to magnesium and the best sources and methods of applying the element to the soil. It was found that rapidly growing crops, such as potatoes, cabbage, spinach, cucumbers, and corn, have a definite period in their growth during which their magnesium need is very high, and if not available the results are yellowing of the lower leaves. On the basis of 13 farms, potato yields were increased 6.8 bbl. per acre on the average by the inclusion of magnesium in the fertilizer. Dolomitic limestone fine enough so that 80 percent could pass a 100-mesh sieve was also a satisfactory source of magnesium for carrots, beets, sorghum, beans, peas, onions, eggplants, spinach, turnips, and radishes. With cabbage the inclusion of 1 percent of some soluble source of magnesia along with the dolomitic limestone was found desirable. In addition to increasing the yields the magnesium increased the proportion of heads that could be cut at the first harvest. Soluble magnesium was also beneficial

in the case of peppers, cucumbers, tomatoes, and corn. In no case was magnesium in either soluble or insoluble form harmful to the crops. Limes containing from 10 to 37 percent of magnesium oxide are available in Virginia and are recommended for use. Calcined kieserite and sulfate of potash magnesia are suggested as soluble materials when a large magnesium deficiency exists. The regular use of green manures and the judicious use of dolomitic limestone are believed the most feasible measures for preventing magnesium deficiency.

The production of cucumbers for pickling purposes, H. L. SEATON, R. HUTSON, and J. H. MUNCIE (*Michigan Sta. Spec. Bul. 273 (1936), pp. 40, figs. 14*).—Based largely on experimental results and on extensive field surveys in the producing areas, information is presented on the climatic, soil, and cultural requirements and on the control of insect and fungus pests. In general heavy clays and poor sands were not found suitable for cucumber production, fertile sandy loams underlaid with clay subsoil being ideal. On almost all soils stable manures were decidedly profitable, and if unavailable must be substituted by soiling crops. As to the time of planting, the best stands and the largest yields were secured at East Lansing when the seeds were sown about 4 weeks after the average date of the last killing frost, somewhere between June 1 and 10. The desirability of planting in full sunlight was shown in an experiment at East Lansing where interplanting with sweet corn reduced yields and returns. The importance of adequate pollination was shown in cage experiments in which plants caged without insects were highly unproductive as compared with open-pollinated plants. The percentages of straight fruits were much higher in the open.

A summary of cultural recommendations is presented for the benefit of growers.

Growing peas for canning in Washington, C. L. VINCENT (*Washington Sta. Pop. Bul. 150 (1936), pp. 28, figs. 10*).—In this general discussion there is presented information relative to the present status of pea canning in the State, climatic and soil requirements, fertilization, culture, varieties, harvesting, utilization, and control of diseases and insects.

Some factors which influence the germination of pepper seeds, H. L. COCHRAN (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 477–480*).—Of several factors studied at Cornell University as to their effects on the germination of pepper seeds, temperature was found to have the most profound influence. The number of days required from planting until the first seedlings appeared decreased rapidly as the temperature was raised from 50°–60° to 90°–100° F. At 40°–50° no germination occurred in 45 days, but upon shifting the seed to 90°–100° rapid germination followed. Soaking the seeds in tap water at 71° prior to planting had no significant effect on the speed of germination and subirrigating the seed boxes actually reduced the percentage of germination at all temperatures, apparently due to the cooling of the soil.

The culture of table stock rutabagas in the Upper Peninsula of Michigan, B. R. CHURCHILL (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 259–262, fig. 1*).—In a test at the Upper Peninsula Experiment Station at Chatham of 11 varieties of rutabagas, the Perfect Model variety was most productive, with a total yield of nearly 18 tons per acre. Cultural tests indicated the desirability of preparing a thoroughly pulverized seedbed and firming the soil either immediately before or after planting. Rows 30 in. apart and plants 10 in. apart in the row are recommended. Under the conditions, planting on or before June 15 was found desirable.

Variations in fleshiness of tomato fruits as affected by fertilization, K. K. KRAUSCHE and B. E. GILBERT (*Plant Physiol., 11 (1936), No. 3, pp. 641–645, figs. 2*).—Studies by the Rhode Island Experiment Station on fruits of Pritchard

tomatoes grown under differential fertilizer treatments indicated that high nitrogen tends toward fruits with relatively less flesh than that of low-nitrogen plants. The use of excessive amounts of nitrogen in the fertilizer may thus produce fruits with such large cavities as to reduce quality. However, since the flesh of the low-nitrogen fruits tended to be less firm, the authors suggest that a medium nitrogen fertilization treatment should be most desirable.

A new method of growing seedlings [trans. title], R. VON VEH (*Züchter, 8 (1936), No. 6, pp. 145–151, figs. 11*).—A method of germinating freshly harvested apple, pear, and quince seeds is described in which the seeds after 1 or 2 days' immersion in tap water are divested of their outer seed coats and the embryos germinated in petri dishes held at room temperature. A layer of ground cork floating on water was found a desirable medium upon which to place the embryos. After 10–14 days the seedlings were transferred to a mixture of one-half peat and one-half sand. In early spring the young plants were moved to an outdoor bed and exposed to frost. When returned to the greenhouse, rapid development ensued. With this technic plants were developed in 8 mo. to a size reached ordinarily in 20 mo.

Pollination studies with Golden Delicious, Minkler, and Arkansas varieties of apples, A. E. MURNEEK (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 1–3*).—In these studies, conducted by the Missouri Experiment Station, it was found that Golden Delicious is an effective pollinizer for Grimes Golden, Delicious, Stayman, and Winesap, and it is included with Delicious, Jonathan, and Ben Davis as the four varieties suitable for pollinizing orchards in the Central States. In crossing Minkler and Arkansas with several varieties it was evident that Grimes Golden is a poor pollinizer for both, yielding no fruit in the case of Arkansas. Cross-incompatibility was thus indicated in the Arkansas Grimes Golden combination.

Notes on pollination of Northern Spy, L. JOLEY (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 240–242*).—Stating that the late-blooming habit of Northern Spy presents a pollination problem in certain orchards, the author tested Northwestern Greening, Mother, and Red Canada pollens and obtained good sets of fruit in all cases. Since Northwestern Greening is a poor pollen producer, its practical value as a pollinizer for Northern Spy is questioned. Phenological observations in the spring of 1935 showed that when half of the Northern Spy blooms were open 77 percent of McIntosh blooms had dropped their petals and 89 percent of the anthers had dehisced. Mother, Northwestern Greening, and Tolman Sweet apparently overlapped Northern Spy very well. Williams, found in other experiments to produce abundant pollen and to pollinate Northern Spy effectively, and Mother are suggested for planting with Northern Spy.

Pre-harvest spraying of apples for removal of lead residues, H. N. WORTHLEY and D. E. H. FREAR (*Jour. Econ. Ent., 29 (1936), No. 3, pp. 524–526*).—Three materials, hydrated lime 10 lb. per 100 gal. of water, ammonium nitrate 8 lb. per 100 gal. water, and paste Vatsol 0.5 lb. per 100 gal. of water, were applied by the Pennsylvania Experiment Station on September 15 to 18-year-old Stayman Winesap and York Imperial trees to test their value in facilitating the removal of residues. In only one instance, that of Stayman Winesap sprayed with lead arsenate plus mineral oil emulsion, did any of the materials appear to increase the loss of lead to a significant degree. Vatsol showed considerable benefit in this single test, although the residues at harvest were far above the legal tolerances. With the possible exception of lime, the supplementary sprays exerted little beneficial effect on the removal of residues by hydrochloric acid solution in a flotation washer. Since it was necessary to wash all the fruit

with hydrochloric acid, none of the treatments are considered practical except possibly for orchards where the fruit exceeds the tolerance by slight margins.

The removal of fluorine spray residue from apples sprayed with natural cryolite, K. GROVES, R. E. MARSHALL, F. L. OVERLEY, and J. L. ST. JOHN (*Washington Sta. Bul. 329 (1936), pp. 15*).—Stating that large amounts of fluorine compounds are now used in Washington apple orchards but that their use has been limited by difficulties in residue removal, the authors discuss the results of washing experiments with apples sprayed according to prescribed schedules and for the most part cleansed with the experimental machine developed by the college. Of 322 fluorine determinations, 178 were the results of three washes of five different samples. In one test in which samples in the same lot of sprayed fruit were washed on 7 different days and a total of 17 analyses were made, there was an average of 0.014 grain of fluorine per pound of fruit. The minimum was 0 008 and the maximum 0.025 grain per pound. Thus an average residue below the tolerance did not necessarily mean satisfactory cleansing.

A number of trials were conducted with aluminum chloride as one solution in a tandem with sodium silicate. The results were unsatisfactory, as the aluminum chloride apparently formed a gummy deposit on the surface of the apple wax and this deposit was not completely removed in the water rinse. There was no noticeable improvement when 1 percent of mineral oil was added. Minor variations in the washing procedure, such as the use of brushes or rollers, changes in the sequence of the washes, or the addition of oil to the acid or to the sodium silicate, did not alter materially the results. Tandem washes with hydrochloric acid and oil as the first wash were not effective. Without the oil the data showed no advantage for either sequence for the hydrochloric acid. Apples washed in solutions containing mineral oil lost moisture and shriveled more rapidly in storage than those washed without oil. The authors point out that with one exception the spray programs followed were severe from the residue removal standpoint, yet in general they conclude that too much confidence should not be placed on one season's results.

The Old Home pear as a pollinizer for standard varieties, S. JOHNSTON (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 218, 219*).—In tests conducted at South Haven and East Lansing satisfactory sets of Bartlett, Beurre Bosc, Seckel, Clapp Favorite, Howell, Kieffer, and Flemish Beauty were secured with Old Home as the pollen parent.

Factors influencing the yields of Montmorency cherry orchards in Michigan, V. R. GARDNER (*Michigan Sta. Spec. Bul. 275 (1936), pp. 18, figs. 4*).—Records taken in Michigan orchards distributed over a wide area and on different types of soil indicated that Montmorency cherries generally reached their peak of production when about 21 yr. of age, but that high production may be maintained over several years. On good soil and with good care Montmorency trees should remain profitable for many years. A study of trunk circumference measurements in a random sample of 44 representative Montmorency orchards indicated that the trees on the average had attained only three-fourths the size that would be possible if they had all been located on first-grade soil. A very close correlation was shown between growth and yield, indicating that yields were correspondingly decreased on the poorer soils.

Climatic influences were observed to vary with the site. Yield records on a random sample of 422 orchards covering periods of from 3 to 9 yr. in each orchard showed that on the average one crop out of three is lost because of spring frosts. On the other hand, on the third of the orchards located on the better sites crop losses from frosts occur less frequently than once in 5 yr. Fruit setting records

taken at South Haven and Grand Rapids showed considerable variation in any one orchard from year to year and between orchards in any one year. The population of available bees is believed to be an important consideration in setting.

From an economic standpoint the author concludes that, on the basis of prices that have prevailed during recent years and general production, substantial profits from the growing of Montmorency cherries may be realized only when the yields are maintained well above the general average of 50 lb. of cherries per tree per year.

Approximate germination test for non-afterripened peach seed, H. B. TUKEY and M. S. BARRETT (*Plant Physiol., 11 (1936), No. 3, pp. 629–633, fig. 1*).—Peach pits obtained from a wide variation of sources were tested in autumn by the artificial culture of the naked embryo on various agars in search of a rapid method of determining in advance of sowing a knowledge of the potential germination. For comparison similar lots of pits were cracked and the seeds placed intact in moist peat moss at 5° C: Still other lots were handled according to the customary nursery planting practices. In general, the percentage of seeds germinating in the embryo culture trials checked rather closely with the afterripening method and also with the results secured following the commercial nursery practice. The author believes that the embryo cultural method may have possibilities as a rapid test for germinability of peach pits. The inclusion of glucose or sucrose in the agar media appeared to exert an inhibiting effect on the growth of the cultured embryos, and in general the absence of nutrients is considered an advantage because of a reduction in contaminating organisms.

Some studies of the degree of maturity of peaches at harvest in relation to flesh firmness, keeping quality, and edible texture, M. A. BLAKE and O. W. DAVIDSON (*New Jersey Stas. Bul. 606 (1936), pp. 35, figs. 5*).—An examination of Elberta peaches harvested at different stages of maturity from trees in high carbohydrate, medium-high carbohydrate, and a high nitrogen growth status showed that fruits from the high and medium-high carbohydrate trees contained from 30 to 75 percent more reducing sugars than did the fruits from the high-nitrogen trees. Sucrose concentrations were higher and acid concentrations lower in both carbohydrate groups than in the high-nitrogen group. However, when the fruits were picked in the soft-ripe stage the differences in sucrose and acid concentrations were practically insignificant, except in the case of green fruits taken from the interior of the high-nitrogen trees. These green peaches were consistently lower in sugars and higher in acids than any of the other fruits under study.

Storage investigations showed important losses in weight during storage both by evaporation and respiration in fruit held at room temperatures. Since peaches contain only very small amounts of reserves from which sugars and acids may be formed during storage, there was no improvement in quality after picking. The comparative shipping or keeping qualities of peaches of different varieties or of peaches grown under different nutrient or environmental treatments could be determined only by a series of pressure tests adequate to measure the rate of softening of the flesh. Elberta peaches 10 cc of the juice of which required more than 15 cc of 0.1 N alkali for neutralization, together with a total sugar concentration of less than 7 percent, are described as distinctly sour and immature in taste and flavor. Fruits from high-nitrogen and low-carbohydrate trees were deficient in red color and sugar, possessed maximum pubescence for the variety, ripened unevenly, and were high in acids and low in flavor.

Fiftieth anniversary of the Lausanne Viticultural Station, 1886–1936, E. CHUARD, F. PORCHET, and H. FAES (*Cinquantenaire de la station viticole de Lausanne, 1886–1936. Lausanne: Impr. Concorde, 1936, pp. 83, figs. 27*).—This

memorial treatise discusses the origin, personnel, and work in viticulture, wine manufacture, pomology, entomology, and plant pathology, and presents a complete bibliography of station contributions.

Behavior of citrus fruit under special respiratory conditions as an expedient index of vitality, E. M. HARVEY and G. L. RYGG (*Plant Physiol., 11 (1936), No. 3, pp. 647–651, figs 3*).—Utilizing jars equipped with mercury manometers, the pressure changes were measured for several different fruits and vegetables as respiration altered from approximately normal to the anaerobic type. The majority of the tests were run at 72° F., although other temperatures, such as 38°, 42°, 46°, and 56°, were employed. A temperature of 56° proved satisfactory except that the period of observation was almost double that at 72°. Fruit having an initial respiratory ratio of less than unity began to develop a negative pressure at once, but after the development of nearly anaerobic conditions the pressure rose. Fruit with an initial respiratory ratio considerably greater than unity began to develop positive pressure immediately. The results indicate that the method may have value as a simple and rapid test of maturity or vitality of fruits and vegetables.

An unusual citrus rootstock, F. F. HALMA (*Jour. Heredity, 27 (1936), No. 5, pp. 204, 205, fig. 1*).—In this brief note mention is made of a lemon orchard in California, the rootstocks of which were found also to be lemons. When propagated, the rootstocks bore very long fruits, none of which contained seeds.

FORESTRY

[Forestry studies by the Indiana Station] (*Indiana Sta. Rpt. 1935, pp. 40–42*).—Brief discussions are presented on wood lot management on the Pinney-Purdue Experiment Farm, windbreak plantings in Jasper County, the marketing of basket veneer and handle stock, and a survey of the timber resources and marketing practices in Dubois County.

Age-size relationships of Hearts Content, a virgin forest in northwestern Pennsylvania, H. F. MOREY (*Ecology, 17 (1936), No. 2, pp. 251–257*).—Determination of the ages, heights, and diameters at breast height of some 800 trees of leading species, such as hemlock, beech, white pine, red and white oaks, black and yellow birches, and red maple, showed a good correlation between age and diameter at breast height for the major species, but the dispersion of the data about the curved averages was too great to allow accurate estimation of age from diameter at breast height. Height correlation and low standard errors for the height-diameter at breast height curves permitted estimation of height from diameter at breast height with a fair degree of accuracy.

The zone of effective windbreak influence, D. DENUYL (*Jour. Forestry, 34 (1936), No. 7, pp. 689–695*).—Records taken by the Indiana Experiment Station on the windbreaking effects of different types of shelterbelts, (1) a single row of Norway spruce, (2) rows, one of Austrian pine and the other Norway spruce, (3) 4 rows of Norway spruce, and (4) a single row of green willow, showed that the effective zone of wind velocity reduction depends not only upon the type of windbreak and prevailing velocity of the wind but also upon the amount of protection required to meet a specific need. The angle with which the wind approaches the barrier is also an important factor in effectiveness. The higher the wind velocity above a certain point the less the percentage reduction at any given distance from the windbreak.

Preplanting treatment of black cherry seed, R. R. PATON (*Jour. Forestry, 34 (1936), No. 7, p. 730*).—From the results of a test of five methods, (1) fermenation followed by washing, (2) fermentation without washing, (3) addition of lye to the fermenting process, (4) mashing without fermentation or wash-

ing, and (5) no treatment, the author concludes that it is not necessary to treat black cherry seeds in any way unless early germination is desired, and then fermenting of the seed is helpful.

A note on germination methods for coniferous species, N. T. MIROV (*Jour. Forestry, 34 (1936), No. 7, pp. 719–723*).—Presenting data to show that the germination of several species of California conifers was increased materially by stratification of the seed at 40° F., the author points out the probability that many germination trials with forest seeds have given erroneous information because of the failure to recognize the natural requirements of the seeds.

Viability of conifer seed as affected by seed moisture content and kiln temperature, W. G. MORRIS (*Jour. Agr. Res. [U. S.], 52 (1936), No. 11, pp. 855–864, figs. 2*).—Using Douglas fir and ponderosa pine seeds extracted by air drying of the cones, it was found that dry Douglas fir seed, that is, containing 7 percent moisture, was not injured by heating for 3 hr. at 50° C., but when the moisture content was 30 percent there was a great loss in germination. At 60° dry seed germinated normally, whereas with 30 percent or more moisture 0.5 hr. at this temperature caused complete failure. Since freshly harvested cones contain much more than 30 percent moisture, it is suggested that heating may be harmful. Increments as little as 5° may, under certain conditions, decrease the germination of either Douglas fir or ponderosa pine seeds by more than 30 percent. In unventilated drying chambers the temperature at various points may differ by 5°.

Three factors, namely, temperature, seed moisture content, and duration of the heating period, are concerned in kiln drying. Unless the factors are approaching the critical point, a slight increase in any one may not be dangerous, but when cones are being dried near the critical heat point an increase in any one of the three factors without a corresponding decrease in another may be serious.

In conclusion the author points out that it is imperative that there should be a thorough circulation of drying air around every cone and advises that cones must be spread in a thin layer to expedite drying. Drying should begin at about 40° and be increased to approximately 55° if the seed moisture content has been reduced to 20 percent or less. Moisture contents should be determined and the temperatures regulated accordingly.

Stratification of white pine seed to speed germination of spring-sown seed, P. W. ROBBINS (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 245, 246*).—White pine seeds, known to germinate slowly and irregularly when planted in the spring and to suffer severe depredation by mice when planted without protection in the autumn, were stratified in sand in a screened box fully exposed to the winter weather. This seed germinated from 1 to 2 weeks earlier than that held in sealed jars at temperatures of from 40° to 60° F. and compared very favorably with seed sown outdoors in the fall. Because of the cost of constructing mouse-proof frames the stratification method is deemed more desirable.

Some observations on the reaction of pine seedlings to shade, G. A. PEARSON (*Ecology, 17 (1936), No. 2, pp. 270–276, figs. 2*).—Observations in the nursery of the Fort Valley Experimental Forest, near Flagstaff, Ariz., on the growth of ponderosa pine under lath shades of different densities and also in full sunlight showed that direct insolation is most favorable to this species. All of the trees receiving only 10 percent of full sunlight died the first winter and all but two of the trees receiving 20 percent died during the 5-yr. period. Plats in the 50 percent light group made slightly less height growth and only

about half the diameter growth of those in full sunlight. Water was not a limiting factor and all the plats were weeded consistently.

Factors influencing the rate of growth of pine in Arkansas, L. M. TURNER (*Ecology, 17 (1936), No. 2, pp. 227–240*).—Studies by the University of Arkansas on 125 0.25-acre plats of *Pinus echinata* and *P. taeda*, located on 18 soil types or phases of these types, showed a rather high degree of correlation between the rate of height growth and the soil series type, particularly with regard to soils with little variation in topography. A higher degree of correlation was established between the rate of height growth and degree of slope of soil series. Sites affording the highest indices were those on soils that are immature, flat, of high silt or silty sand content, with permeable subsoil, and at least fair drainage, but with obviously adequate water supply. On the other hand, the poorer sites were those with a high degree of slope and hence excessive run-off, or extremely stony, gravelly, or sandy soils of moderate or steep slope. The results of the study are said to suggest the practicability of predicting the tree-growing potentialities of recognizable site complexes.

Red squirrel damage to pine and spruce plantations, A. C. HART (*Jour. Forestry, 34 (1936), No. 7, pp. 729, 730*).—Observations by the Connecticut State College in March 1936, following a winter of heavy and prolonged snow cover, showed much injury to the buds of various conifers from the feeding of red squirrels. Of eight species, namely, Norway, white, and red spruces; Japanese red, Japanese black, white, and Norway pines; and Douglas fir, the Norway and white spruces seemed particularly susceptible to attack. Norway pine when planted in pure stands surrounded by hardwoods was also damaged. White pine, Douglas fir, and the two Japanese pines were free from injury.

Effect of repeated ground fires upon stumpage returns in western white pine, E. F. RAPRAEGER (*Jour. Forestry, 34 (1936), No. 7, pp. 715–718*).—Studies in a plat near Orofino, Idaho, in which the trees averaged 141 yr. and had passed through at least 5 fires, showed 3 notable unfavorable results of the fires, (1) the creation of blank spaces where groups of trees were actually killed, (2) decay traceable to fire injuries, and (3) rough growth due to uneven stocking following the fires. The gross losses were large and pointed to the need of complete protection from the seedling stage to maturity.

Timber growing and logging practice in ponderosa pine in the Northwest, R. H. WEIDMAN (*U. S. Dept. Agr., Tech. Bul. 511 (1936), pp. 92, figs. 15*).—This, the last in a series of 12 papers covering the principal forest regions of the United States, presents as did the earlier ones (1) the measures needed to prevent timber-producing lands from becoming barren, and (2) the measures required to grow valuable timber species. Among subjects considered are slash disposal, fire protection, methods of cutting and logging, the grazing of cut-over lands, control of insects and diseases, erosion control, the conditions suitable for intensive forestry, the meaning of full productivity, growth per acre under intensive forestry, practicability of full timber crops, and plans of management for permanent timber production. Appended are Dunning's tree classification, the essential steps in piling and burning slash, and a summary of the proposed minimum and intensive measures.

Scribner volume tables for cut-over stands of ponderosa pine in Arizona, E. M. HORNIBROOK (*Jour. Agr. Res. [U. S.], 52 (1936), No. 12, pp. 961–974, figs. 10*).—Following the technic of Schumacher and Hall (E. S. R., 70, p. 634), Scribner board-foot volume tables are developed for 3-in. classes of ponderosa pine in cut-over stands on the Malpais soil type in Arizona. The tables are printed in both alinement-chart and tabular form. Comparison of the data for the three age classes indicates that the volume equation for the young "blackjacks"

gives a result not significantly different from that for intermediates, whereas the equation for the oldest "yellow pines" gives a result significantly different from that for the other two classes, separate or combined. It is stated that while the tables evolved will give results within the standard error only if applied to trees in stands similar to those studied, this limitation will cause little difficulty in their use on stands cut under present U. S. D. A. Forest Service practice.

Marketing timber for basket stock in Indiana, R. C. BRUNDAGE (*Indiana Sta. Bul. 408 (1936), pp. 30, figs. 19*).—A survey of the industry showed that over 12,000,000 bd.-ft. of timber were sold to the 10 basket manufacturers in Indiana in 1935. Of this amount approximately 86 percent was secured from southern Indiana. Over 90 percent of the basket stock was beech, cottonwood, elm, hard maple, sweet gum, sycamore, and tulip poplar. Sound logs 14 in. or more in diameter and with straight grain and a maximum amount of light-colored sapwood are preferred for basket stock. There were found three common practices in selling timber, as follows: (1) As standing timber at a lump sum, (2) at a definite price per 1,000 bd.-ft. log scale when cut, and (3) as logs direct to the basket manufacturers. About 30 percent of the total was sold on the lump sum basis. When all grades of timber were averaged, selling by log scale at the farm netted a higher stumpage return than the other two methods, but when only high quality timber or No. 1 logs were averaged, direct sales to the basket companies netted from $1 to $2 more stumpage return. Stumpage prices ranged from $4 to $7 higher in northern than in southern Indiana. Careful bucking of timber produced better grades of logs and blocks and netted greater stumpage returns.

DISEASES OF PLANTS

[Phytopathological studies reported at the convention of the Association of Southern Agricultural Workers, 1933–35] (*Assoc. South. Agr. Workers Proc., 34 (1933), pp. 79, 80; 35 (1934), pp. 232, 310–312, 315, 316, 320, 321, 329–345; 36 (1935), pp. 569–579, 580, 581, 582, 583, 584–591*).—Abstracts of the following papers are included: Persistent Strands of the Cotton Root-Rot Fungus [*Phymatotrichum omnivorum*] in Texas, by H. C. McNamara (pp. 79, 80); Breeding Wilt Resistant Varieties of Cotton, by J. O. Ware and V. H. Young (p. 232); Control of Fire-Blight Infection of Apple Blossoms, by A. M. Musser (pp. 310–312); A Physiological Study of Fruit Development in the Pecan (*Hicoria pecan*), by C. L. Smith and C. J. B. Thor (pp. 315, 316); Nature and Control of *Cladosporium fulvum* (Tomato Leaf Mold), by F. S. Andrews (pp. 320, 321); Studies on Potato Scab [*Actinomyces scabies*] Control, by J. J. Taubenhaus (p. 329); Studies on Nailhead Spot of Tomatoes [Due to *Alternaria tomato* n. comb.], by G. F. Weber (p. 330); Studies on the Control of the Seedling Blight Disease of Rice in Arkansas [Mostly Due to *Helminthosporium oryzae*], by E. M. Cralley (p. 330); Treatment of Sweet Potato Plants for the Control of Black Rot, by L. E. Miles (p. 331); Preliminary Report on an Anthracnose Disease of Lima Beans, by T. D. Persons (pp. 331, 332); A Report on the Use of Creosote Oil to Control San Jose Scale and Peach Leaf Curl, by W. W. Stanley, S. Marcovitch, and J. O. Andes (pp. 332, 333); Recent Investigations of Cotton Root Rot in Texas, by D. C. Neal (pp. 333, 334); Reversible Vegetative Dissociation of Strains of *Phymatotrichum omnivorum*, by W. N. Ezekiel and J. J. Taubenhaus (p. 334); Studies on the *Fusarium* Wilt of Cotton, by V. H. Young and J. O. Ware (p. 335); Seed Treatment Studies With Fungicidal Dusts at the Arkansas Experiment Station (pp. 336,

337) and Observations on the Control of Black Rot [*Guignardia bidwellii*] of Grapes (pp. 337, 338), both by V. H. Young; Progress Report on the Control of Fire Blight, by H. R. Rosen (p. 338); High Points in Apple Spraying in Tennessee, by J. O. Andes (p. 339); Control Measures for Rosette of Blackberries and Dewberries in Louisiana, by A. G. Plakidas (p. 339); *Stilbum* [*cinnabarinum*] on Fig in Louisiana, by E. C. Tims (p. 340); New or Unusual Diseases Reported or Observed in Mississippi in Recent Years, by T. D. Persons (pp. 340, 341); *Sorosphaera veronicae* (Schr.) on Corn or Wall Speedwell, *Veronica arvensis*, by L. Donald (pp. 341, 342); *Verticillium* Wilt of Cotton in Greece, by L. E. Miles (p. 342); Further Studies on the Toxic Principles That Determine Immunity of Monocotyledonous Plants to *Phymatotrichum* Root Rot, by W. N. Ezekiel, J. J. Taubenhaus, and J. F. Fudge (pp. 343, 344); *A Rhizoctonia* Bud Rot in Strawberry, by A. N. Brooks (pp. 569, 570); Mode of Action of Bordeaux on *Mycosphaerella fragariae*, by A. G. Plakidas (p. 570); *Sclerotium rolfsii*, Sacc., on Strawberries and the Effect of Certain Chemicals on the Sclerotia, by R. E. Nolan (pp. 570, 571); Further Studies of Anthracnose and Wilt of Strawberry Caused by *Colletotrichum fragariae*, by A. N. Brooks (pp. 571, 572); A Root Rot of Strawberry Caused by a Species of *Diplodia*, by R. E. Nolan (p. 572); A Bark Disease of Tahiti Lime Trees Caused by *Phomopsis citri* Fawcett and *Diplodia natalensis* Evans, by W. B. Tisdale (pp. 572, 573); The Control of Diseases of Tomato Seedlings, by F. Van Haltern (pp. 573, 574); Preliminary Report on Anthracnose Diseases of Eggplants, by T. D. Persons (pp. 574, 575); The Direct Effect of Bordeaux Mixture, for the Control of Downy Mildew, on Early Cucumber Production, by G. F. Weber (p. 575); On a Black Crown Rot of Greenhouse Snapdragons Caused by *Myrothecium roridum* Tode, by J. J. Taubenhaus (pp. 575, 576); *Sclerotinia* Rot of Irish Potatoes in Florida, by A. H. Eddins (p. 576); Seeds of Watermelons and Okra as Possible Carriers of *Fusarium* Wilt, by J. J. Taubenhaus (p. 576); Control of Sweet Potato Stem Rot in West Tennessee, by G. M. Stone (p. 577); Apple Black Root Rot, by J. O. Andes (p. 577); Effect of Crown Gall, Hairy Root, and Woolly Aphids on Apple Trees in Orchard, by C. D. Sherbakoff and J. A. McClintock (pp. 577, 578); Report of One Year's Test of Copper Fungicides and Other New Materials as Sprays on Peaches, by L. E. Miles (p. 578); Breeding Peanuts for Disease Resistance, by B. B. Higgins (pp. 578, 579); *Lespedeza sericea* Stem Blight, by J. K. Underwood (p. 579); Only Certain Strains of Tobacco Mosaic Cause Mosaic-Burning, by W. D. Valleau and E. M. Johnson (p. 580); Studies on Downy Mildew of Tobacco, by C. B. Sumner and G. M. Armstrong (pp. 580, 581); Tobacco Bed Soil Disinfection, by J. O. Andes (p. 582); Do Necrotic Lesions Result in Localization of Tobacco Mosaic Viruses in *Nicotiana?* by W. D. Valleau (pp. 582, 583); Field Studies of *Fusarium* Wilt of Cotton, by C. D. Sherbakoff and G. M. Stone (p. 583); Angular Leaf Spot of Cotton in Mississippi in 1934, by L. E. Miles (pp. 584, 585); The Etiology of Sore-Shin, or Damping-off, of Cotton (p. 585) and A Résumé of Cottonseed Treatments in South Carolina (pp. 585, 586), both by C. H. Arndt; The Reaction of Several Isolations of the Cotton Wilt Fungus to Toxic Dyes, by G. M. Armstrong and C. N. Clayton (p. 586); Further Studies of the Effect of Ammonia-Nitrogen on the Growth of the Cotton-Root-Rot Fungus, *Phymatotrichum omnivorum*, in Field and Laboratory Experiments, by D. C. Neal (pp. 587, 588); Investigations of the *Verticillium* Wilt Disease of Cotton.—Preliminary Report, by L. E. Miles (p. 588); Dissemination of the Bacterial Leaf-Spot of Cotton, by F. M. Rolfs (p. 589); Wilt Resistant Cottons Adapted to the Gulf Coastal Plains, by D. C. (p. 590); and The Control of Wilt and Rust, by V. H. Young, J. O. Ware, and O. A. Pope (pp. 590, 591).

The Plant Disease Reporter, July 15 and August 1, 1936 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 20 (1936). Nos. 13, pp. 201–217, figs. 2; 14, pp. 219–237*).—The following items noted are of current interest:

No. 13.—Phymatotrichum omnivorum found in Nevada, by C. J. King; a survey of root disease in some conifers and hardwoods caused by *Phytophthora cambivora* (*P. cinnamomi*), by B. S. Crandall; summary of 9 years' experience with rhododendron wilt and root rot due to *P. cambivora*, by R. P. White; simultaneous infections of strawberries with crinkle and yellows (xanthosis), and a probable first report for the United States of anther and stigma blight of Youngberry (a hybrid dewberry) in Oregon, due to *Haplosphaeria deformans*, both by S. M. Zeller; a phosphorus soil deficiency disease causing unusual damage to corn in central Illinois, by B. Koehler; diseases of Austrian winter peas, by J. L. Weimer; and droughts in the United States, by J. B. Kincer.

No. 14.—First blister rust (*Cronartium ribicola*) found in California (on *Ribes* and *Pinus lambertiana*), by W. W. Wagener and J. L. Mielke; an epiphytotic of algal spot (*Cephaleuros*) on a wide variety of host plants in southern Florida, by G. D. Ruehle; tomato diseases destructive in Mississippi—drought a contributing factor, by P. R. Miller; and curly top of tomato in Utah, by H. L. Blood.

[Phytopathological studies by the Indiana Station] (*Indiana Sta. Rpt. 1935, pp. 23–27, 47, 57, 58, figs. 5*).—Progress reports are given on corn disease investigations (in cooperation with the U. S. D. A. Bureau of Plant Industry), including breeding and selection for resistance to diseases and abnormal conditions, as well as for better corn types; wheat disease investigations; *Phytophthora cactorum* trunk canker of apples; tomato diseases; aster wilt; potash deficiency symptoms in growing plants; spray residues as influenced by spray schedules and washing treatments; and the effect of leaf rust (*Puccinia triticina*) on the yield, composition, and quality of wheat (in cooperation with the U. S. D. A. Bureau of Plant Industry).

Kansas mycological notes, 1934, C. L. Lefebvre and C. O. Johnston (*Kans. Acad. Sci. Trans., 38 (1935), pp. 101–103*).—This contribution by the Kansas Experiment Station gives miscellaneous notes on noteworthy species of fungi, including diseases that are apparently becoming more definitely established in the State, the incidence and effects of climatic factors with reference to diseases of small grains and corn, *Diatrype stigma* on oaks, *Nummularia clypeus* on soft maple, *Phyllosticta apiculis* on golden willow (*Salix vitellina*), *Gymnosporangium globosum* on hawthorn (*Crataegus crus-galli*), rotting of floor timbers by *Poria incrassata*, and a list of 14 species of fungi recently collected (10 species not previously recorded for the State).

[Phytopathological studies by the Rhode Island Station] (*Rhode Island Sta. Rpt. [1935], pp. 18–20, 23, 24, 26–28*).—Progress reports are given on studies of visible spray burn on apple leaves by lime-sulfur and copper sulfate solutions; the influence of sprays on CO_2 assimilation by apple leaves; apple orchard spray tests with various lime-sulfur and bordeaux mixtures; spray injury to tomato leaves, and the influence of environmental factors; the pink patch turf disease (*Corticium fuciforme*) and its control; and spray tests with late tomatoes in the field, using various copper fungicides.

[Phytopathological studies by the Tennessee Station] (*Tennessee Sta. Rpt. 1934, pp. 15, 28, 29–32*).—Progress reports are included on the breeding and selection of tomato varieties resistant to leaf spot, by S. H. Essary; selection of pears for resistance to fire blight, and chemical control of nematodes, by B. D. Drain; wheat head blight and root rot, by C. D. Sherbakoff; spray tests against black rot, fire blight, and other prevailing apple diseases, by

J. O. Andes; and selection of cotton strains for resistance to *Verticillium* wilt, by Stone.

The problem of specialization and variation in phytopathogenic fungi, E. C. STAKMAN (*6. Internatl. Bot. Cong., Amsterdam, 1935, Proc., vol. 1, pp. 30–35*).—This contribution by the University of Minnesota sets forth briefly the general principles involved and the present state of our knowledge of the subject, and summarizes the work of the university on the problem of the origin of new races of certain smut fungi (particularly corn smut).

Notes on southern Appalachian fungi, L. R. HESLER (*Jour. Tenn. Acad. Sci., 11 (1936), No. 2, pp. 107–122, figs. 7*).—This contribution by the University of Tennessee is an annotated list of fungi (Ascomycetes, Uredinales, Tremellales, Thelephoraceae, Hydnaceae, Polyporaceae, Agaricaceae, and Fungi Imperfecti) collected in the State, including two first reports for North America (*Stereum duriusculum* and *Tremella tuberculariа*), several species out of their reported range, and new hosts or substrates for various fungi.

The development of Lycoperdon acuminatum, D. SWARTZ (*Mycologia, 28 (1936), No. 3, pp. 278–283, figs. 9*) —This contribution from the University of Arkansas describes the developmental stages of the species, comparisons with other species showing it to be most closely related to *L. wrightii*.

Plant viruses, K. M. SMITH (*London: Methuen & Co., [1935], pp. IX+107, figs. 11*).—The author's stated aim was "to bring to the notice of workers in other branches of science, and particularly botanists and entomologists, some of the more interesting and important facts of the study of plant viruses. . . . The references [94 titles] at the end of the book are not intended to be exhaustive but are selected as being representative of the main lines of plant virus research." They include references through 1934, with a few for 1935. The work constitutes a comprehensive, critical, analytical review, including a historical sketch of the earlier work on the group, the technic of study, natural modes of transmission, the virus in and outside of the host and in the insect vector, immunity, the nature and classification of viruses, control of virus diseases, and comparisons between the plant and animal viruses.

A brief index is provided.

The ring symptom of virus diseases of plants, E. M. JOHNSON and W. D. VALLEAU (*Kentucky Sta. Bul. 361 (1935), pp. 239–263, figs. 11*).—"Chlorotic or necrotic rings may be present as the only definite symptom or as an accompanying symptom in plants affected with various virus diseases. Rings may be present as local symptoms on inoculated leaves or as transitory or permanent symptoms on uninoculated, completely, or partially invaded tissue.

"The following tobaccco viruses capable of producing rings in tobacco are discussed: Ring tobacco mosaic (2 strains), yellow and white mosaic, cucumber mosaics, etch viruses, viruses from *Delphinium* sp., *Plantago major*, and *Mertensia virginica* (possibly cucumber mosaic), and two unidentified viruses. Rings are also described as prominent symptoms in virus diseases of peony, lilac, delphinium, pepper, red clover, sweetclover, apple, plum, rose, and New England aster.

"It is suggested that the ring symptom is not diagnostic for any specific virus disease because similar rings may occur in plants, especially tobacco, affected with such unlike viruses as tobacco ring spot, healthy potato, etch, tobacco mosaics, cucumber mosaics, and others. Usually other symptoms accompany the rings which make classification possible, but sometimes property and host-range studies may be necessary for more exact classification."

Studies on the effect of carborundum as an abrasive in plant virus inoculations, T. E. RAWLINS and C. M. TOMPKINS (*Phytopathology, 26 (1936), No. 6, pp. 578–587, fig. 1*).—By the use of 600-mesh, powdered carborundum dur-

ing inoculation, it was possible in these studies at the University of California to transmit readily a number of viruses hitherto refractory by other methods. Among these viruses are those causing spotted wilt of tomato and lettuce, broadbean mosaic, a California celery mosaic, cauliflower mosaic, and sugar beet mosaic. Attempts to transmit curly top of sugar beet, California aster or celery yellows, or brown blight and big vein of lettuce were unsuccessful.

Histological studies demonstrated that in leaves inoculated by this method the epidermal cells are frequently pierced by the carborundum crystals and that the points of the crystals are small relative to the cell size. This evidence favors the theory that the crystals may pierce leaf cells and allow virus particles to enter, but in certain cases do not injure the pierced cells sufficiently to prevent virus multiplications therein.

Further experiments on the question of the relation of mildew resistance to plant nutrition [trans. title], E. Lowig (*Ernähr. Pflanze, 32 (1936), No. 4, pp. 61–67, figs. 18*).—From experiments with oats, meadow grass, orchard grass, crimson clover, and *Phalaris arundinacea* it is concluded that silicic acid in the form of its potassium salts and also as a constituent of Thomas meal possesses a protective action against mildew. From these results, together with the work of other investigators, it is considered that this increase in mildew resistance is a specific effect of silicic acid.

Between the nitrogen content and mildew infection there was, within certain limits, a direct proportionality.

Analyses indicated that with silicic acid fertilization the silicon content in the plant could be considerably raised.

Preparation of bordeaux mixture with special reference to the use of commercial hydrated lime, O. Butler (*New Hampshire Sta. Circ. 49 (1936), pp. 8, figs. 2*).—Bordeaux mixtures made with equal weights of quicklime or of commercial hydrated lime are not equivalent, and substitution of the latter in a bordeaux formula affects both the transparency and the adhesive quality of the mixture (the former only slightly, but the latter noticeably and adversely when mixtures of the type of 4–2–50 are used). The dispersion of the copper precipitate in bordeaux mixture is readily measured by the rate of settling. In mixtures using strong lime to weak copper or the reverse, good results follow in both cases if quicklime is used, but when commercial hydrated limes are employed the sedimentation rate is markedly affected by the strength of the mixture in $CuSO_4$, the ratio of $CuSO_4$ to lime, and the method of mixing, but practically not at all by the fineness of the hydrate used when the method of mixing forms washes settling at the same rate as the preparation from quicklime. "The data also show that whenever strong lime to weak copper produces rapidly settling mixtures then the fineness of the hydrated lime substantially affects the rate of settlement and a distinct benefit ensues from the use of very finely ground commercial hydrate. And conversely when bordeaux mixtures are prepared from commercial hydrated limes, the degree of fineness of the lime used is without importance when strong copper to weak lime is the method of mixing employed."

Based on the data obtained, detailed procedures for the preparation of bordeaux mixtures are given.

Greenhouse wires and pipes galvanized with zinc react with sulphur dioxide to form soluble zinc salts, K. J. Kadow, W. A. Ruth, and H. W. Anderson (*Phytopathology, 26 (1936), No. 6, pp. 609, 610*).—This note from the University of Illinois reports injury to tomatoes due to the dripping of condensed moisture from zinc-galvanized pipes and wires following sulfur dioxide fumigation used against several greenhouse diseases.

Some of the factors influencing the infection and pathogenicity of Ustilago zeae (Beckm.) Unger on Zea mays L., G. N. DAVIS (*Iowa Sta. Res. Bul. 199 (1936), pp. 247–278, figs. 12*).—A survey (near Ames, Iowa) of corn smut based on visible smut galls, from 1930 to 1934, showed 10 6, 9.9, 13 9, 5.5, and 18 3 percent of affected plants, respectively. When the leaf sheaths were stripped from 1,985 plants exposed to natural and artificial infection in 1934, many small smut galls (39.3 percent of the total expressed infections) were found at the nodes.

A decrease in surface tension of the inoculum increased its infectivity. Of 500 Golden Bantam plants, 92 percent became infected when inoculated with a sporidial suspension in carrot filtrate plus 1 percent fish-oil soap, while of 90 similar plants 36.6 percent became infected when inoculated with a suspension in carrot filtrate alone.

Increased bud growth was accompanied by a larger number of nodal infections. Axillary bud growth was stimulated by injury to the plant or by inhibition of pollination. Injured or unpollinated plants produced about twice as many smut galls as the controls. Histological examination of 262 axillary buds from 50 inoculated Golden Bantam plants showed 53.6 percent of the buds with smut mycelium. Mycelium was found in apparently healthy axillary buds 67 days after inoculation.

The percentage of smut infection as indicated by nodal smut galls increased with lateness of planting, an average for 2 yr. showing 12 percent on May 15 plantings and about 40 percent on June 4 plantings. The percentage of infection as indicated by nodal smut galls showed a tendency to increase both ways from the 2–3 rates of planting. For 1931 to 1934, inclusive, those plants growing 1 to a hill showed 40.8, 20.4, 9, and 22.8 percent infection, respectively; those at 3 to a hill 22.5, 13.5, 4.3, and 14.6 percent; and those at 5 per hill 32.4, 21.6, 5 9, and 18.5 percent.

Effect of treatment of oats on the development of saccharogenic and dextrinogenic amylases during germination, N. M. NAYLOR and V. L. DAWSON (*Iowa State Col. Jour. Sci., 10 (1936), No. 3, pp. 267–274*).—In this study at Iowa State College, fumigation of grain with the heavier-than-air vapors of carbon disulfide, ethylene dichloride, and ethylene oxide-carbon dioxide were effective in controlling fungus growths. The carbon-disulfide treated grain germinated well and showed rapid development of saccharogenic and dextrinogenic enzymes high in activity. Grain treated with ethylene oxide-carbon dioxide germinated slowly and showed no appreciable increase in amylase activity until the fifth day of germination. This treatment affected the saccharogenic and dextrinogenic enzymes alike, apparently slowing up enzyme production or causing permanent injury to it. Ethylene dichloride had a greater depressing effect on the saccharogenic than on the dextrinogenic enzyme.

Enzyme precipitates were made from extracts of carbon-disulfide treated oats germinated for 3 and for 8 days. Fractional precipitation with alcohol produced an enzyme preparation of high activity from the extract of the oats germinated 8 days. From this extract, the 65 percent alcohol precipitate showed a saccharogenic power of 695 and a dextrinogenic power of 83,300.

Relation of stomatal function of wheat to invasion and infection by leaf rust (Puccinia triticina), R. M. CALDWELL and G. M. STONE (*Jour. Agr. Res. [U. S.], 52 (1936), No. 12, pp. 917–932, figs. 4*).—In this cooperative contribution by the Indiana Experiment Station and the U. S. D. A. Bureau of Plant Industry, a simple technic is described for studying the entrance phenomena of a rust in relation to stomatal aperture. This involves stripping the inoculated epidermis away from the mesophyll cells and fixation in absolute alcohol containing a suitable stain. The initial open condition of stomata of seedling

wheat, prior to appressorium formation, proved to be unnecessary to the entry of *P. triticina* (18 cultures comprising 7 physiologic forms). Limited studies suggested the same relation for mature plants. The normally closed stomata of wheat seedlings provided no openings through which the entry hyphae could pass without first overcoming the resistance exerted by the tightly closed guard cells. When an appressorium was initiated on an open stoma of a seedling leaf, the stoma closed tightly prior to entry. The appressorium originating from the urediospore appeared to function as a specialized organ for applying pressure between the closed guard cells, thereby effecting a forceful opening of the stoma and entry by the fungus. Since closed stomata offered no effective barrier, it was concluded that there is no possibility of "functional resistance" to this rust through delayed morning opening of stomata. Appressoria of clover rust (*Uromyces trifolii*) also caused wheat stomata to close, and were observed to effect numerous entries through initially closed stomata of seedling wheat leaves.

The stem rust epidemic of 1935 in Kansas, C. O. JOHNSTON, L. E. MELCHERS, H. H. LAUDE, and J. H. PARKER (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1936, Sup. 92, pp. 19–30, figs. 3*).—This contribution by the Kansas Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry gives a survey of the known factors in this epidemic, which was the first one of major importance since 1923 and the most severe and destructive since that of 1904. It is concluded that the proper combination of the following factors was responsible: Heavy infection of very susceptible wheats in north-central Texas; prevailing southerly winds of the central plains area which carried rust spores into Kansas during May and June; heavy and frequent rains, high relative humidities, frequent dews, and favorable temperatures during the last half of May and all of June; late tillering and heading due to early spring drought; a long fruiting period brought about by heavy rains and subnormal temperatures of May and June; and the susceptibility of commercial wheat varieties in Kansas.

Several years' observations have shown that wheat stem rust overwinters with annual regularity in central and southern Texas, and that the susceptible Mediterranean wheat of north-central Texas furnishes an ideal propagation ground. Severe epidemics of stem rust thus can be expected to sweep northward whenever the proper sequence of favorable conditions occurs. The experience of 1935 would indicate a definite need for stem rust-resistant varieties both for north-central Texas and for the hard red winter wheat area of the central plains.

Inheritance of resistance to the common mosaic virus in the bean, M. C. PARKER (*Jour. Agr. Res. [U. S.], 52 (1936), No. 12, pp. 895–915, fig. 1*).—In this cooperative study between the Wisconsin Experiment Station and the U. S. D. A. Bureau of Plant Industry reciprocal crosses between the mosaic-resistant Michigan Robust and the susceptible Stringless Green Refugee varieties reacted quite differently to the mosaic virus employed. It was found that the maternal parent governs to a large extent the reaction of the hybrid offspring. In the F_1, all plants were susceptible from the cross Stringless Green Refugee × Michigan Robust, and 82 percent were resistant from the cross Michigan Robust × Stringless Green Refugee. The influence of the grandmaternal parent was still very evident in the F_2. From the cross Stringless Green Refugee × Michigan Robust, 99 percent of the F_2 were susceptible to mosaic, whereas 56 percent from the reciprocal cross were resistant. In the F_2 the reciprocal crosses were still very different. From the cross susceptible × resistant, 91 percent were susceptible and 9 percent resistant. From resistant × susceptible, 35 percent of the F_2 were resistant and 65 percent susceptible. Throughout the

three generations studied there was evidenced a very marked convergence of results. Corbett Refugee (resistant) was also used in reciprocal crosses with the above varieties, with results still different from those between Stringless Green Refugee and Michigan Robust. All F_1 individuals of the reciprocal crosses were resistant, but a difference appeared in the F_2. Corbett Refugee × Michigan Robust gave 7 percent susceptibles in the F_2, and Michigan Robust × Corbett Refugee 9 percent.

The dominant influence of the maternal parent in the reaction of hybrids is explained by assuming that the cytoplasm or some extranuclear inclusion governs the immediate reaction of the plant to the virus, and that, although the ultimate control of expression is nuclear, the expression of the action of the genes is delayed. It is further assumed that certain genotypes change the reaction of the cytoplasm more rapidly than others.

Comparative studies of some European and American potato viroses, T. P. DYKSTRA (*Phytopathology, 26 (1936), No. 6, pp. 597–606, figs. 4*).—In this cooperative study by the Oregon Experiment Station and the U. S. D. A. Bureau of Plant Industry, a number of potato varieties from both continents were tested against the viruses in question. Virus X was found to be similar to the so-called latent virus of "healthy" American commercial potatoes. Virus Y and the vein-banding virus (rugose mosaic complex with the X component removed) belong to the same group but are not identical. Paracrinkle does not resemble leaf-rolling mosaic or any other known American virosis. Crinkle A is not identical with rugose mosaic, but resembles mild mosaic, though the mottled pattern differs somewhat and the crinkling is less severe. Virus C does not resemble any of the known American forms of potato viruses. Details as to varieties used and symptoms obtained are given.

Seed transmission of potato virus diseases, D. REDDICK (*Amer. Potato Jour., 13 (1936), No. 5, pp. 118–124*).—It was found in this study at Cornell University that seed transmission of the potato virus disease acropetal necrosis [=vein-banding virus?] occurs in a low percentage of cases. Some evidence is presented pointing to the possibility that virus entry into the embryo may be effected through the pollen. The findings are significant in potato-breeding programs where newly produced plants must be grown in the open, and especially in regions where *Myzus persicae* is likely to be prevalent. Inferential evidence is also presented that acronecrosis and leaf roll, also caused by viruses, may be transmitted through the true seed.

The value of disease-free foundation stock for breeding purposes is indicated. The proportion of healthy offspring from diseased parents is so high that a particular plant of great value may be used as either parent in hybridization, even though affected with a communicable disease of virus type. In cases where diseased plants have been used in a cross, the production of the first crop of seedlings under conditions permitting complete control of virus-disease vectors is indicated.

The yellows and mosaic diseases of sugar beets and fodder beets [trans. title].—**I, History of the investigation on virus yellows and mosaic,** H. M. QUANJER; **II, Investigation on virus yellows and some remarks on mosaic,** G. ROLAND (*Tijdschr. Plantenziekten, 42 (1936), No. 3, pp. 45–70, pls. 5; Eng. abs., pp. 64–66*).—This is a general summary of the published results of studies on these beet diseases.

The curly-top resistant beet variety, A. W. SKUDERNA, C. PRICE, J. O. CULBERTSON, and C. E. CORMANY (*Facts About Sugar, 31 (1936), No. 1, p. 17*).—In field plantings (1932–34) in certain beet-growing areas of California, Idaho, Utah, and Colorado, the U. S. No. 1 variety far surpassed in resistance the commercial brands with which it was compared and the yields and quality

were satisfactory. In years of greatest curly top severity this variety outyielded the commercial brands, on an average, by 4 tons or more of beets per acre.

Some indications of a relation of soil fertility and plant nutrition to cane diseases in Hawaii, A. F. HECK (*Jour. Amer. Soc. Agron., 26 (1934), No. 5, pp. 381–389*).—This chemical study of cane juice and of the soil conditions under which cane is produced, made at the Wisconsin Experiment Station, seems to indicate a correlation between readily available plant nutrients and susceptibility to some Hawaiian cane diseases. Growth failure appears to be due to a *Pythium* (*P. aphanidermatum*) root rot induced under an unbalanced nutrition in which low phosphorus and high mineral nitrogen are more or less outstanding. The history of the sugar industry in Hawaii seems to indicate that this trouble has been on the increase.

Eye leaf spot (*Helminthosporium sacchari*) damage is usually associated with high mineral nitrogen and perhaps low potassium, but more especially with the former. The most damage is done by the "runner" and less by the immediate lesion.

Brown stripe (*H. stenospilum*) seems to be associated with low mineral assimilation, which may be low for phosphorus or potassium or for both, or it may be associated with an unbalanced condition of phosphorus and potassium with nitrogen. The evidence seems to show that assimilation of sufficient phosphorus and potassium in a balanced relation aids greatly in minimizing the injury from this disease. Resistant varieties usually are either berter feeders on the phosphorus and potassium of the soil or are able to make normal growth by using less of these nutrients in their metabolism, thus leaving more of them in solution in the juice.

Notes on Pythium root rot.—VIII, Absorption of essential elements by segregated roots of sugar cane, C. W. CARPENTER (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 40 (1936), No. 2, pp. 137–142, figs. 4*).—Studies previously reported (E. S. R., 72, p. 798) indicated that different roots could supply the plant with specific elements available in their vicinity and that soil solutions corresponding to a complete nutrient solution thus might not be required at any one point in the soil for the plant to function normally. These results led to the experiments here described, wherein each of the nine elements considered essential for normal cane growth was supplied to individual plants through a separate root by a technic described in detail. For each of the tests, three plants of uniform size were selected. One was held as a control and grown continuously in a complete nutrient solution. All but ten of the roots of each of the other two plants were excised, and nine roots of each were detoured, respectively, into the nine solutions, each of which contained a salt supplying one of the nine essential elements (viz, N, P, K, Ca, Mg, Fe, Mn, B, and Si). The tenth root of each plant was detoured into distilled water. The experiment was repeated, and in both cases the dissimilarity in the roots in the various solutions was striking. The largest mass of white, vigorous roots developed in the calcium chloride solution. These root masses were in marked contrast to those developing in any of the other solutions. It is not assumed that these limited tests are complete enough for far reaching interpretations, but it is thought that experiments of this nature may provide useful information regarding the cane plant.

In pot tests with the Hamakua growth-failure soil, here noted, applications of phosphorus and calcium tended to increase the resistance of cane and Sudan grass to Pythium root rot. It was also shown that part of the response following large applications of phosphate to certain soils was due to the calcium portion of the fertilizer.

Physical properties of sugarcane mosaic virus, S. A. RAFAY (*Indian Jour. Agr. Sci., 5 (1935), No. 6, pp. 663–670, fig. 1*).—Using a standardized technic here described, this virus was shown to resemble crinkle mosaic of potato in tolerating a 1:10 dilution, but it lost its potency in 2 hr. whereas the virus of spotted wilt of tomato is inactivated in 6 hr. The filter paper filtrate was noninfective, but the residue induced mosaic. This virus is reported to be one of the most sensitive and least resistant to chemical reagents, as tested against HCl, HNO_3, $HgCl_2$, NaCl, $CuSO_4$, H_2O_2, formalin, zinc powder, and MgO_4.

Tobacco diseases, W. D. VALLEAU and E. M. JOHNSON (*Kentucky Sta. Bul. 362 (1936), pp. 62, figs. 28*).—This handbook first takes up recommendations for the control of tobacco diseases in Kentucky and gives a general discussion of the causes of these diseases and of the relation of the soil to them. The main body of the text then deals with specific diseases under the following groupings: Physiological diseases, plant bed diseases, seed treatment, and root, leaf, virus, and stalk diseases. A final section deals with houseburn, which results from the growth of micro-organisms in the dead leaves during periods of high humidity in the curing house.

Downy mildew (blue mold) of tobacco (*N. C. Dept. Agr. Bul., 1934, Dec., pp. 16, figs. 6*).—This is a general discussion of tobacco blue mold, including the history of the disease, the hosts, symptoms, and cause; the factors influencing the occurrence, rate of spread, and degree of destructiveness; and a summary of measures for its prevention and control. The results reported are largely from cooperative work between the Tobacco Experiment Station of the North Carolina State Department of Agriculture and Duke University.

Studies on the origin of yellow-mosaic viruses, J. H. JENSEN (*Phytopathology, 26 (1936), No. 3, pp. 266–277, fig. 1*).—Tobacco plants believed to have been infected by single units of tobacco-mosaic virus (because they were exposed to exceedingly small amounts of this virus through inoculations made with single pin punctures or with virus samples reduced to low activity by chemical treatment, ultrafiltration, or high dilution) showed, in addition to the ordinary mottling symptoms, occasional bright yellow spots on their leaves. From these spots yellow-mosaic strains were isolated that were distinct from tobacco mosaic. Thus further evidence was brought that yellow-mosaic viruses arise in plants infected with tobacco-mosaic virus. On the basis of rates of movement in host plants, on infectivity, and on symptom differences, it is concluded that many, if not all, of the 51 yellow-mosaic strains isolated from yellow spots differ from each other and from tobacco mosaic, and yet certain properties, host reactions, and serological relationships demonstrate them to be strains of tobacco-mosaic virus.

These findings are believed to indicate that new strains of virus arise suddenly in plants affected with tobacco mosaic by some process similar to mutation in species of living organisms.—(*Courtesy Biol. Abs.*)

Susceptibility of tobacco plants visibly affected with mild tobacco mosaic to other strains of the virus, E. M. JOHNSON and W. D. VALLEAU (*Kentucky Sta. Bul. 360 (1935), pp. 192–201, figs. 2*).—"Turkish tobacco plants having 6 to 7 leaves were inoculated with various natural strains of mild green tobacco mosaic and, 7 to 15 days later, when infection was systemic, with the virus of white or yellow tobacco mosaic. When mild mosaic plants were inoculated with either white or yellow tobacco mosaic on leaves not previously inoculated, they developed symptoms of white or yellow tobacco mosaic in the tip leaves in 10 to 19 days. Similar plants inoculated with either white or yellow mosaic only showed symptoms in the tip leaves in 7 to 10 days. When inoculations were made with white mosaic on leaves previously rubbed with mild mosaic, symptoms of white mosaic were visible in the new leaves of some of the plants

in 20 to 60 days. Symptoms of white or yellow mosaic were slightly less conspicuous and appeared later in plants affected with mild mosaic than in plants affected with only white or yellow mosaic."

Localization and resistance to tobacco mosaic, in Nicotiana, W. D. VALLEAU (*Kentucky Sta. Bul. 360 (1935), pp. 203–230, figs. 7*).—Several strains of tobacco-mosaic virus collected in Kentucky cause necrotic spotting in certain tobacco varieties, but this property may be lost from such a virus. The majority of Kentucky-grown varieties develop necrotic spots when inoculated with white or aucuba mosaic. Localization of the latter occurred in the inoculated leaf in 40 percent of 130 necrotic-spotting plants growing in the field, and systemic infection of the remainder was accompanied with extreme necrosis. In the mosaic-resistant variety Ambalema, necrotic-spotting viruses appear to be completely localized in the necrotic spots. No sharp line can be drawn between localization and the usual systemic infection of tobacco plants with the common tobacco-mosaic viruses. A complete series between these extremes can be demonstrated if a series of *N. glutinosa*, *N. langsdorffii*, *N. sanderae*, *N. rustica*, and *N. tabacum* plants of different ages are inoculated with several tobacco-mosaic viruses differing greatly in symptom expression. Necrotic spotting is merely an index to the degree of cellular sensitivity to the virus, and the term "localization", if used, should be reserved for cases of necrotic spotting where the virus is confined within the inoculated leaf. Localization cannot be expected to have value in the control of mosaic in our present varieties of tobacco, because the common strains of tobacco mosaic are nonnecrotic-spotting strains.

It is concluded that two types of resistance to the tobacco-mosaic viruses may be recognized in *N. tabacum*, viz, one in which certain strains of the virus are sometimes prevented from inducing systemic infection by a high degree of sensitivity in the invaded cells, with localization in inoculated leaves, and a second type exemplified in the resistance shown by Ambalema to nonnecrotic virus strains, in which the virus is inhibited from entering the young tissues. Failure of a virus to enter the seeds may thus be due to its inability to invade meristematic tissue. It is suggested that plants which are most sensitive to a virus (necrotic-spotting forms) are those in which the virus multiplies most rapidly (e. g., *N. glutinosa*), and those least sensitive are plants in which the virus finds the poorest medium for multiplication (e. g., Ambalema). It is believed that a transfer of the resistance of Ambalema, either with or without necrotic spotting, to our commercial varieties should prove a practical solution of the tobacco-mosaic problem.

Burning and non-burning strains of tobacco mosaic, W. D. VALLEAU and E. M. JOHNSON (*Kentucky Sta. Bul. 361 (1935), pp. 233–238, fig. 1*).—Mosaic burn, a disease affecting some of the leaves of mosaic plants which are without mosaic patterns, appeared in plants inoculated from "burned" plants, but not in those inoculated with nonburning strains of virus. The evidence is also sufficient to show that there are several burn strains which differ in symptoms. Of 35 White Burley varieties or hybrids, 22 of dark air-cured and dark fired tobacco, and 11 F_1 hybrids of Kentucky tobaccos with Ambalema, and plants of Ambalema inoculated with a burning strain of mosaic virus, all except Ambalema developed readily observable mosaic burn. Mosaic burn is evidently an invasive symptom, as it is apparently limited almost entirely to tissue young enough to be invaded rapidly by the virus, but does not occur on leaves with completed growth at the time of inoculation or in those produced after the appearance of mosaic symptoms in the growing point. Burn on leaves with mosaic patterns was usually confined to the older, patternless, distal part of the leaf. The symptoms range from a few nearly circular, necrotic spots to

numerous coalescing spots which finally kill the tissue of large areas of the leaf. Infection of White Burley tobacco with either a burning or a nonburning strain at topping time sometimes tends to improve rather than injure the quality. The distribution of mosaic burn is probably coextensive with the tobacco industry.

Factors affecting the formation of local lesions by tobacco mosaic virus, J. CALDWELL (*Roy. Soc. [London], Ser. B, 119 (1936), No. 815, pp. 493–507, pl. 1, figs. 3*).—Many viruses produce local lesions when the plant juices containing them are rubbed on the leaves of appropriate plants. It is known that this effect may be reduced or even abolished by the addition of certain substances, e. g., normal serum, to the virus-holding juice. The action of these inhibitory substances may be either directly on the virus itself, e. g., by neutralizing its infectivity, or indirectly on the leaves of the rubbed plant, e. g., by reducing their susceptibility, and it is a matter of some moment to distinguish between these two modes of action. A method is suggested whereby the distinction can be made by comparing the effects of dilution of the virus and of the inhibitory substance. The action of various enzymes on the virus activity is discussed, and in particular the effect of trypsin is studied experimentally and shown to be in the main an action on the virus not necessarily proteolytic. The inactivating effects of normal serum and of silver nitrate are studied and found also to be due to action on the virus. The use of the method described may make possible a direct chemical examination of the virus agent, even in the presence of other constituents of the plant juice.

Mosaic from tobacco one to fifty-two years old, E. M. JOHNSON and W. D. VALLEAU (*Kentucky Sta. Bul. 361 (1935), pp. 264–271, figs. 2*).—Decoctions of 41 ground samples from 24 to 39 yr. old were used to inoculate 241 Turkish tobacco plants never touched by hands, of which 45 (representing 17 samples) developed mosaic of several recognizable strains. Seventy-six samples from 1 to 15 yr. old and known to contain mosaic when collected were used to inoculate 84 tobacco plants, of which 79 developed mosaic. There was no evident loss in infectivity in dried tobacco until after 8 yr. At least 12 strains of virus were tested and all survived in dried tobacco. Dried leaves from tobacco grown in 1882, used as inoculum on 30 plants, caused mosaic in 18, 2 strains, a yellow and a green distorting type, appearing.

The isolation of crystalline tobacco mosaic virus protein from diseased tomato plants, W. M. STANLEY and H. S. LORING (*Science, 83 (1936), No. 2148, p. 85*).—Using the technic previously reported (E. S. R., 73, p. 800), but with certain improvements, a crystalline protein was isolated from mosaicked tomato plants, possessing the same physical, chemical, and biological properties as those found for the protein from mosaicked tobacco plants. These results are believed to offer additional evidence for the identity of the protein with the agent responsible for the tobacco-mosaic disease.

Do tobacco plants recover from and develop immunity to ringspot? W. D. VALLEAU (*Kentucky Sta. Bul. 360 (1935), pp. 181–191, figs. 4*).—From the author's studies, combined with data from the literature, it is concluded that there are two sets of symptoms—invasive and occupative or systemic—and the ring and line patterns, as invasive symptoms, are not confined to the ring spot virus. There are many virus diseases in which the early, invasive symptoms differ markedly from the later symptoms. In ring spot-infected plants the later, patternless leaves continue to carry the virus in a rather high concentration, and infected plants can frequently be identified in the field, when no patterns can be seen, by the peculiar chlorosis or necrosis of the leaf edges of lateral shoots. The best reason for believing that ring spot plants do not recover is suggested by

the behavior of the yellowing strain previously described by the author (E. S. R., 68, p. 208).

"If we accept the proposition that the development of ring patterns occurs as the result of the invasion of masses of healthy tissue by the virus, and that the plant is still diseased following the production of patternless leaves, then the problem of immunity does not seem to enter into the failure of a second inoculation to produce rings. The cells of the patternless leaves are already affected to the limit by the virus, and the addition of a few more units of the virus to an occasional cell cannot be expected to produce an effect. If now we consider the protective effect of one strain of a virus against a more injurious strain, it would seem that exactly the same phenomenon is concerned as in the case of ring spot. . . . It appears better, for the time being, to speak of protection afforded by one strain of virus against a more injurious strain . . . rather than to speak of an acquired immunity in the sense in which this term is used in animal and human pathology."

Fruit diseases in 1935, W. D. MILLS (*N. Y. State Hort. Soc. Proc., 81 (1936), pp. 13–17*).—In this contribution by the [New York] Cornell Experiment Station notes are given on diseases of apples (including spray injury and the severe outbreak of scab), stone fruits, pear, quince, grape, and strawberry.

Little-leaf or rosette of fruit trees, IV, W. H. CHANDLER, D. R. HOAGLAND, and P. L. HIBBARD (*Amer. Soc. Hort. Sci. Proc., 31 (1934), pp. 11–19, figs. 3*).—Additional observations and experiments by the University of California (E. S. R., 72, p. 478) indicated that where the zinc fixation powers of soils are high treatment of the soil with zinc compounds is too costly, the results are uncertain, and the duration of the healthy condition of the tree is reduced. Additions of ferrous sulfate, gypsum, or ammonium sulfate to the zinc sulfate ($ZnSO_4$) failed to give the benefits which at first seemed apparent. Of affected peach, apricot, plum, citrus, and walnut trees sprayed with a $ZnSO_4$-lime mixture on the young foliage in the spring or early summer, all but the last benefited—citrus showing the best results. With or without lime, $ZnSO_4$ sprayed on mature foliage of peach, apricot, plum, apple, and walnut trees gave strong responses except for walnut. Spraying tests apparently indicated the inadvisability of using lime with the dormant $ZnSO_4$ treatment. It is believed that the beneficial effects of dormant spraying would be greater after a second annual application. Brushing fresh pruning wounds with strong $ZnSO_4$ gave better results with grapevines than with fruit trees. Driving of zinc-coated nails and pieces of zinc into the wood gave evidence of benefits through absorption, but before the results from this method, as compared with other treatments, can be ascertained more evidence must be accumulated regarding the danger of injury. Zinc phosphate and zinc carbonate (among the least soluble of zinc compounds) gave no improvement, nor did salts of aluminum, potassium, sodium, strontium, uranium, zirconium, and titanium.

Evidence is given that a tree may be making weak growth as a result of whatever it is that zinc corrects without developing either the characteristic spring rosettes of little leaves or the summer mottling.

Studies of the little-leaf disease in California, W. S. BALLARD and R. C. LINDLER (*Amer. Soc. Hort. Sci. Proc., 31 (1934), pp. 1–10*).—In these studies on the cause and control of little leaf, pot cultures of grapes containing various amounts and combinations of salts that might occur in alkali soils all failed to induce development of the disease, even when the soils used were from corral spots where little leaf had previously killed peach trees. Badly affected grapevines on a corral spot were cut back and grafted with healthy scions, but the latter developed little leaf. However, when a part of these vines were

transplanted to a different locality they all recovered. Diseased vines were replaced with healthy nursery stock, whereupon the latter developed little leaf. Cuttings from badly affected vines, when rooted in coarse, washed sand and later planted in fertile soil or sand in containers, all failed to develop little leaf. An experimental planting of fruit trees and grapes was made in a corral spot where badly diseased peach trees had been growing. Within 1 yr. or more little leaf had developed on peach, plum, pecan, apple, and walnut trees and on the grapevines so planted. A cover crop of alfalfa materially reduced the amount of little leaf in a vineyard so treated.

Soil treatment tests with various salts and acids were carried out in the field on various fruit trees and grapevines, only the zinc salts giving favorable results. The data indicated the dormant season to be the best time to apply the zinc sulfate soil treatment, as various fruits showed marked differences in susceptibility to injury. Of 45 organic and inorganic compounds tested by direct introduction into the trees or vines, only the soluble zinc salts have thus far produced unmistakable results. Of the zinc sprays tried, the zinc sulfate-ammonia produced the most striking results.

Whether the action of zinc is direct or indirect is undetermined, but the authors believe that these troubles are probably zinc deficiency diseases, though the final settlement of the problem rests on the growing of susceptible plants in a zinc-free medium. If these diseases are due to an injurious substance from the soil or produced in the plant, it would seem that some of the other metallic ions experimentally introduced should have rendered such a substance innocuous. On the other hand, if they are zinc deficiencies, the action of cover crops requires explanation. Finally, it is stated that no case of little leaf characters or of zinc deficiency has been reported for any annual plant.

Cherry leaf spot control, G. W. Keitt (*Canning Trade, 58 (1936), No. 32, pp. 7, 8; also in Canning Age, 17 (1936), No. 4, pp. 169, 170*).—This is a contribution from the Wisconsin Experiment Station.

A report of progress on studies of prune russet ("scab") and its control, P. W. Miller (*Oreg. State Hort. Soc. Ann. Rpt., 27 (1935), pp. 106–122, figs. 4*).—Russet, one of the major troubles of prunes in Oregon and Washington and occurring in practically all prune-growing sections of the Pacific Northwest, was studied during 1935 with the following preliminary conclusions:

Affected fruits are disfigured, causing considerable economic loss. Fruits are typically affected at an early stage or shortly after the time of shuck fall, the critical period for russet development extending for about 1 mo. thereafter. When about three-fourths grown, the prunes apparently become highly resistant. Russet is definitely nonparasitic in nature and appears to be due principally to mechanical injury from the rubbing of twigs, etc., against the young fruits during windy periods. Pruning and suitable windbreaks are suggested as possible methods of reducing the incidence and severity of the injury.

Immunological studies on the three peach diseases, yellows, rosette, and little peach, L. O. Kunkel (*Phytopathology, 26 (1936), No. 3, pp. 201–219, figs. 6*).—In experiments designed to show whether trees affected by any one of the three peach viruses—yellows, rosette, or little peach—would acquire immunity from either of the other two, trees with little peach proved immune to yellows, and trees with yellows immune to little peach. Neither yellows nor little peach trees were immune to rosette. Yellows buds transplanted to little peach trees produced shoots with typical little peach, and little peach buds transplanted to yellows trees shoots with typical yellows. Subinoculations from these shoots transmitted the disease carried by the tree on which the bud was transplanted. Trees inoculated simultaneously with little peach and yellows buds at different levels of their stems contracted the disease carried by the bud in the

upper position. Shoots from the lower bud bore symptoms of, and transmitted, the disease carried by the upper bud.

These results are held to indicate that little peach and yellows are strains of the same disease, that both are distinct from rosette, and that the point of inoculation determines whether yellows or little peach shall prevail in any given tree.

Further studies on zinc sulfate in peach sprays, with limited tests in apple sprays, K. J. KADOW and H. W. ANDERSON (*Illinois Sta. Bul. 424 (1936), pp. 129–144*).—Terminating this 7-yr. study, the following conclusions are drawn in addition to the confirmation of results previously noted (E. S. R., 73, p. 496):

Small amounts of zinc sulfate ($ZnSO_4$) appeared to be as efficient as larger amounts in reducing water-soluble arsenic in peach sprays consisting of acid lead arsenate and hydrated lime or of mixtures of acid lead arsenate and calcium carbonate. Under average field conditions, 1 lb. in 100 gal. of water, with 3 lb. of acid lead arsenate and 3 lb. of hydrated lime, was apparently sufficient to reduce spray injury effectively. With $ZnSO_4$ in apple sprays at 8 lb. to 100 gal. of water plus acid lead arsenate and lime, or with from 4- to 5-lb. applications of $CuSO_4$ in bordeaux mixture, russet resulted on Ben Davis apples. The effects of small amounts of $ZnSO_4$ on apples was not determined. Data on the insecticidal value of $ZnSO_4$ have not been conclusive, but apparently it has no marked influence on codling moth control.

The results obtained preclude the recommendation of $ZnSO_4$ as a fungicide in peach or apple sprays. In laboratory tests it proved much more toxic to apple scab (*Venturia inaequalis*) than to brown rot (*Sclerotinia fructicola*), but under field conditions it was only 65 percent effective against apple scab. No significant data were obtained relative to its control of brown rot, but laboratory tests would indicate very little value in this respect. From two to three lead arsenate-lime sprays for curculio, with or without $ZnSO_4$, are usually sufficient to control peach scab in Illinois, but acid lead arsenate and lime should never be applied to peaches under field conditions in the State without adding $ZnSO_4$.

Zinc sulfate was not observed to impart any "stimulating effect" to the peach under Illinois field conditions.

A study of the toxic action on gray-mold spores of cleaning solutions used in spray residue removal, O. F. SCHNELLHARDT and F. D. HEALD (*Phytopathology, 26 (1936), No. 6, pp. 564–577, figs. 2*).—Washing tanks for removal of spray residue are one of the main sources of contamination of apples with gray mold (*Botrytis cinerea*). The cleaning solutions commonly used for spray residue removal are, however, toxic to gray mold spores and consequently reduce the load of viable spores. Of the three cleaners used in these tests at the Washington Experiment Station, sodium silicate was most toxic, hydrochloric acid less so, and sodium carbonate of least effect. The temperature of cleaning solutions affected their toxicity, the kill being progressively increased from 90° to 120° F.

The control of raspberry mosaics, L. M. COOLEY (*N. Y. State Hort. Soc. Proc., 81 (1936), pp. 277, 278*).—In this note from the New York State Experiment Station, the control measures outlined advocate the use of resistant varieties or of healthy stock combined with isolation and roguing. These diseases are reported to present the most serious problem for small fruits in the Hudson Valley.

The Phytophthora disease of strawberry, I, II (*Sci. Hort. [Wye, Kent, Eng.], 4 (1936), pp. 52–58*).—The following two sections are included:

I. *Pathological investigations,* N. L. Alcock (pp. 52–56).—The symptoms and successful inoculation tests, using diseased roots containing oospores of the

Phytophthora, are described. Some thousands of attempts at cultivation of the fungus, carried out by the author and others, have thus far failed, but a tentative life history is outlined. Nine yr. of study in the laboratory and field have indicated the etiological relations and virulence of the disease and its ready transmission by affected plants.

Experiments in control have thus far given disappointing results, but certain general suggestions are given and the possibility of developing resistant varieties is pointed out.

II. *The Phytophthora disease in the field*, D. V. Howells (pp. 50–58).—The history and incidence of the disease in Scotland are briefly outlined, and its transmission (largely by infected plants) and course in the field are discussed. Four epidemics (the first in 1921), as outlined, illustrate the more important practical aspects of the disease.

A method of harvesting grapefruit to retard stem-end rot, J. R. Winston (*U. S. Dept. Agr. Circ. 396 (1936), pp. 8, figs. 6*).—Except when very ripe, pulled grapefruits proved to be less rapidly affected by stem-end rot than when clipped. Borax treatment at the packing house was very effective in further reducing both stem-end rot and blue mold. Pulling is especially recommended for fruit intended for storage or export.

Effects of storage and holding conditions on Alternaria in lemons, H. S. Fawcett, L. J. Klotz, and H. W. Nixon (*Calif. Citrogr., 21 (1936), No. 4, pp. 118, 143, 144, figs. 2*).—Since *Alternaria* decay often causes serious losses in lemons held in cold storage, an experiment was conducted (1935) by the California Citrus Experiment Station in cooperation with the Fruit Growers' Exchange. The results indicated that lemons from the air-conditioned, refrigerated storage room (lot A) were superior in keeping quality to those from the naturally ventilated one (lot B). After removal and placement in cabinets held at various temperatures, the lemons of lot A continued to show a greater resistance to *Alternaria* than those of lot B. The greater resistance to break-down was considered as due to the more constant temperature and humidity and to the smaller accumulation of deleterious substances, as indicated by the lower concentration of carbon dioxide in the air-conditioned room. From 59° F. upward lot B showed a rapid increase in the fungus and in indications of its presence, while lot A did not do so until a temperature of 65° was attained. The greater amount of *Alternaria* in lot B was correlated with a much higher percentage of black buttons after 6 months' storage.

The condition of the fruit when taken from storage thus appears to be a reliable indication of its later keeping quality.

Bark disease of Tahiti lime and Perrine lemon, W. B. Tisdale (*Florida Sta. Press Bul. 481 (1935), pp. 2*).—This is a semipopular account of a bark disease due to *Diplodia* and *Phomopsis*, and of suggested control measures.

Investigations of Nectria diseases in hardwoods of New England, P. Spaulding, T. J. Grant, and T. T. Ayers (*Jour. Forestry, 34 (1936), No. 2, pp. 169–179, fig. 1*).—It is concluded from this study that in silvicultural work *Nectria*-cankered trees should be used for cordwood and the slash burned where economically feasible, and those left should be girdled or felled. Cankers occur even in sapling stands and should receive special attention. The consistent discrimination against *Nectria*-cankered trees throughout the life of a stand up to large pole size should control this disease effectively.

Moisture is a strong factor in relation to *Nectria* fruiting, but its practical importance cannot yet be evaluated.

Red maple, sweet birch, and yellow birch are most often cankered, while white ash, white oak, scarlet oak, and American elm are not commonly affected in New England. Cross inoculations indicated that canker-forming Nectrias

go freely from one hardwood species to most others, and the fact that weed species such as mountain maple and striped maple harbor these fungi gives an additional reason for removing them from hardwood stands when practicable.

The beech *Cryptococcus-Nectria* disease of south-central and eastern Maine is due to a complex of injury by the insect and of fungus attack in the injured bark, causing death in severely affected trees. Diseased trees were also found infected by *Nectria* spp. other than the one commonly associated with this insect.

Cedar rust and its control in the Hudson Valley, J. M. HAMILTON (*N. Y. State Hort. Soc. Proc., 81 (1936), pp. 216–221*).—In this contribution by the New York State Experiment Station, it is stated that cedar rust on apple trees has been increasingly destructive in this region, *Gymnosporangium juniperi-virginianae, G. globosum*, and *G. germinale* or *G. clavipes* all being concerned. The distribution, symptoms, other hosts, and the relations of climatic factors as studied under the local conditions are briefly described, together with a combined spray schedule for both scab and rust.

New facts concerning Cephalosporium wilt of elms, D. B. CREAGER (*Jour. Arnold Arboretum, 16 (1935), No. 4, pp. 453, 454*).—Attention is called to two kinds of reproductive bodies—naked spore heads and pycnidia. The latter, a new type of fructification for *Cephalosporium*, produce abundant spores which remain viable over winter. Wounds in the leaves provide the most common infection court for mycelium or either type of spore, and a yellowing around this court is an early symptom of typical leaf infection.

The results of preliminary tests for control by eradication and by fungicides and insecticides are briefly noted.

A heart rot of magnolia caused by Fomes geotropus, H. W. JOHNSON and C. W. EDGERTON (*Mycologia, 28 (1936), No. 3, pp. 292–295, fig. 1*).—In this study from the Louisiana State University, *F. geotropus* was found constantly associated with and evidently the cause of, a heart rot of *Magnolia grandiflora*. It appears to be responsible for the destruction of many of the old trees in southern Louisiana, and to be the first record of this fungus attacking the species.

Maple wilt, F. C. STRONG (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 225–227*).—The symptoms of *Verticillium* attack are described. In early stages of the disease, fertilization of the trees with ample watering when necessary is reported to have resulted in good growth and disappearance of symptoms. It is not known how permanent these results may prove to be. Removal is advised for badly affected trees. In replanting, avoidance of the susceptible Norway maple, hard maple, American elm, and Japanese barberry is recommended.

Pathogenicity and cultural experiments with Caliciopsis pinea, W. W. RAY (*Mycologia, 28 (1936), No. 3, pp. 201–208, figs. 6*).—In this investigation from Cornell University, inoculations with mycelium and spores from pure cultures indicated that *C. pinea* is parasitic for white pine, causing sharply delimited cankers on the trunk and branches. Spermagonia and mature stromatic columns containing asci and spores were developed in culture.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Planning for wildlife in the United States (*Natl. Resources Bd., Land Planning Com. Sup. Rpt., 1935, pt. 9, pp. V+24, figs. 2*).—Section 1 of this supplementary report (pp. 1–11) deals with the requirements for wildlife areas, section 2 (pp. 12–14) with policies with respect to wildlife, and section 3 (pp. 15–24) with wildlife management in national forests. The report was prepared

under the direction of a committee of eight, with M. L. Wilson serving as chairman and L. C. Gray as director, the first two sections being contributed by the U. S. D. A. Bureau of Biological Survey and the third by the Forest Service.

Forest wildlife census methods applicable to New England conditions, N. W. HOSLEY ET AL. (*Jour. Forestry, 34 (1936), No 5, pp. 467–471*).—This is a report of the New England Section Subcommittee on Fish and Game Management.

Natural history of vertebrates (except birds): A laboratory and field guide, F. N. BLANCHARD (*Ann Arbor, Mich.: Edwards Bros., 1935, rev., pp. II+82, fig. 1*).—This is a revised edition of a photolithoprint reproduction of a manuscript, the first edition of which appeared in 1932. Following the introductory account, which includes a list of equipment needed, directions on collecting and preserving animals, and special problems, mammals (pp. 6–30), amphibians (pp. 31–51), reptiles (pp. 52–70), and fishes (pp. 71–82), respectively, are considered, a rather complete list of references accompanying each.

Deer and dauerwald in Germany, I, II, A. LEOPOLD (*Jour. Forestry, 34 (1936), Nos. 4, pp. 366–375, figs. 5; 5, pp. 460–466*).—Part 1 of this contribution deals with history and part 2 with ecology and policy.

The Capillariinae parasites of mammals (Nematoda: Trichuroidea) [trans. title], J. F. TEIXEIRA DE FREITAS and H. LENT (*Mem. Inst. Oswaldo Cruz, 31 (1936), No. 1, pp. 85–160, pls. 16*).—The synonymy, descriptions, habitat, and geographical distribution of 33 well known and 24 insufficiently known species of the genus *Capillaria* parasitic in mammals is followed by a systematic host list and a bibliography of 21 pages.

The parasites of some North Carolina rodents, R. HARKEMA (*Ecol. Monog., 6 (1936), No 2, pp. 151–232, figs. 5*).—In the introductory part of this contribution the author deals with previous work, materials and methods, and hosts examined. A systematic list is given of the parasites which infested these hosts (pp. 157–160), followed by a summary of the findings also arranged in systematic order, their seasonal variation and infestation being discussed and graphically illustrated (pp. 161–177). A list of the ecto- and endo-parasites that have been reported from North American Rodentia and Lagomorpha, with their hosts, arranged alphabetically by systematic groups (pp. 177–218) follows. Under the name *Syphacia peromysci* n. sp., a description is given in an appendix of a nematode from the white-footed mouse, together with a bibliography of 12 pages.

Choice of rat poison in antiplague work, J. D. LONG (*Pub. Health Rpts. [U. S.], 51 (1936), No. 18, pp. 551–554*).—Antiplague control work with the rat in South America during the last 6 yr. is said to have demonstrated arsenic to be the most satisfactory treatment, it being cheap and always well taken by the rats if care be taken to make the vehicle attractive. It is sufficiently slow in action to allow the rodent to leave and prevent the release of infected fleas within the inhabited premises.

The northern bob-white's winter territory, P. L. ERRINGTON and F. N. HAMERSTROM, JR. (*Iowa Sta. Res. Bul. 201 (1936), pp. 301–443, figs. 26*).—The several parts of this work are devoted to introductory remarks and technic (pp. 305–333), survival data (pp. 333–365), analysis of carrying capacity (pp. 366–405), and management of the bobwhite's winter territory (pp. 405–437). It is based upon the data from intensive population studies which have been carried on over a period of six winters, largely in Iowa and Wisconsin agricultural communities, accounts relating to which have been noted (E. S. R., 75, p. 373).

Direct enumeration census technic was found to be the most useful and reliable in the field researches. "Survival data from the 70 specific bobwhite wintering territories or groups which have been studied for more than one

season indicate that a given tract of environment is capable of accommodating a rather definitely limited population even under optimum weather conditions. The carrying capacity of a tract of land for bobwhites seems generally to remain about the same from one year to the next, although the carrying capacity of each tract of land is by no means the same. Constancy of carrying capacity has been much more apparent on large land units than on small. Carrying capacity of quail environment doubtless changes gradually over a period of years, despite the fact that on our chief observational areas it has remained practically constant for as long as 6 yr. . . .

"The correlation between severity of predation upon wintering bobwhites and carrying capacity of their environment is especially significant. Losses from simple predation suffered by wintering populations within the carrying capacity of their environment, as measured to date, have been uniformly light, rarely at a rate exceeding 6 percent per 90 days. . . .

"On the whole, our evidence indicates that the pressure of native enemies is unlikely to be sufficiently severe to reduce healthy, well-fed wintering bobwhite populations below the carrying capacity of the land. Populations may be reduced below carrying capacity, however, by shooting or trapping, by starvation or other emergencies associated with snow or ice storms, by drought, and probably by disease and unknown factors. Concentrations of the exotic ring-necked pheasant in coverts of strategic importance for quail may cause the latter to avoid those coverts, and may thus in effect lower the carrying capacity of the land for the quail themselves."

A list of 77 references to the literature is included.

Quail breeding manual (*New York: More Game Birds in Amer., 1935, rev. ed., pp. 55, figs. 36*).—This manual presents information on the care of quail breeders during the laying season; care and handling of quail eggs; hatching with Bantam hens and in the incubator; brooding of quail chicks with Bantam hens; rearing in the colony brooder house, the Coleman brooder, and in wire-bottomed growing pens; etc.

Venomous animals of Costa Rica: Intestinal parasites of animals, C. VÍQUEZ (*Animales venenosos de Costa Rica: Parásitos intestinales de nuestros animales. San José: Govt., 1935, pp. IV+5–318, figs.* [83]).—A practical, illustrated account of the poisonous animals, particularly reptiles, met with in Costa Rica is followed by notes on the endoparasites encountered (pp. 159–210), biological chemistry, hematology, etc.

Schistosome dermatitis in Canada: Notes on two causative agents and their snail hosts in Manitoba, W. E. SWALES (*Canad. Jour. Res., 14 (1936), No. 1, Sect. D, pp. 6–10, pl. 1*).—An investigation of "swimmers' itch" at Clear Lake, Manitoba, is said to have revealed the presence of two schistosome cercariae, *Cercaria elvae* Miller 1923 in the snail *Limnea stagnalis jugularis* Say and *Cercaria* sp. in *Stagnicola emarginata canadensis* (Sowerby), both known to cause dermatitis.

Earthworms of Missouri, H. W. OLSON (*Ohio Jour. Sci., 36 (1936), No. 2, pp. 102–113*).—This contribution, based upon personal collections which have extended into 25 counties of the State during a period of 4 yr., presents descriptions and a key for the separation of the 17 forms met with in Missouri.

The pioneer century of American entomology, H. B. WEISS (*New Brunswick, N. J.: Author, 1936, pp.* [3]+320).—This work, in mimeographed form, in which the author traces the record of entomology from its beginning in North America down to the year 1865, deals with the subject in 12 chapters, as follows: Entomology in the accounts of early travelers (1588–1723) (pp. 3–21); the entomology of early books and papers (1731–1800) (pp. 22–57); the early years of the nineteenth century (1800–1817) (pp. 58–86); Thomas Say and his

contemporaries (1817–31) (pp. 87–120); from Zimmerman to Le Conte (1832–45) (pp. 121–163); Asa Fitch and other entomologists (1845–54) (pp. 164–201); the Glover and Osten-Sacken period (1855–60) (pp. 202–233); from Walsh to Cowan (1860–65) (pp. 234–260): the entomology in agricultural periodicals before 1865 (pp. 261–273); scientific societies, scientific journals, and exploring expeditions contributing to the progress of American entomology (pp. 274–286); some notes on Canada (pp. 287–301); and entomology in Europe during the pioneer century in America (pp. 302–309).

A bibliography of 25 references and an index are included.

A résumé of insect conditions in Florida in 1935 and some pointers for 1936, J. R. WATSON (*Citrus Indus., 17 (1936), No. 2, pp. 13, 14*).—A practical contribution from the Florida Experiment Station.

[Report of work in economic zoology and entomology by the Indiana Station] (*Indiana Sta. Rpt. 1935, pp. 33–37, 42, 43, figs. 2*).—The work of the year referred to (E. S. R., 73, p. 205) includes data on the European corn borer; control of the potato leafhopper, tarnished plant bug, striped cucumber beetle, and cabbage looper; oriental fruit moth; codling moth insecticide tests, timing sprays, screening packing houses, chemically treated bands, cavity fillers, orchard sanitation through burning of the floor cover, and the use of lights in trapping moths; the Japanese beetle; and quail studies.

Insectae Borinquenses: A revised annotated check-list of the insects of Puerto Rico, G. N. WOLCOTT; **A host-plant index**, J. I. OTERO (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 20 (1936), No. 1, pp. 627, figs. 192*).—A revision is presented by Wolcott of the annotated check list of the insects of Puerto Rico previously noted (E. S. R., 53, p. 51), which includes a host plant index to Insectae Borinquenses, by Otero (pp. 601–627).

[Report of work in entomology by the Tennessee Station], S. MARCOVITCH (*Tennessee Sta. Rpt. 1934, pp. 24–27*).—The progress of work during the year (E. S. R., 73, p. 205) with the melon aphid, cutworms, bean and cowpea weevils, and tobacco insects is briefly referred to, and reference is made to the more important insects of the year.

[Contributions on economic insects in Quebec] (*Quebec Soc. Protect. Plants Ann. Rpt., 27 (1934–35), pp. 46–49, 57–65, 84–105, fig. 1*).—The following contributions are presented: Some Outstanding Entomological Events of 1934, by G. Maheux (pp. 46–49); The Asparagus Beetles, by J. I. Beaulne (pp. 57–60); The Number of Larval Instars of *Dendroctonus piceaperda* Hopk. as Determined by Dyar's Rule, by A. R. Gobeil (pp. 60–65); Wireworm Survey in Tobacco Fields of the Yamaska Valley (Preliminary Report), by R. Bordeleau (pp. 84–87); The Entomological Record, 1934, by W. J. Brown (pp. 87–95); and A Preliminary List of Insects of the Province of Quebec—Part IV, The Odonata, by E. M. Walker (pp. 96–105).

Miscellaneous physiological observations on the laboratory breeding of flesh flies and of Melanoplus bivittatus Say, A. W. A. BROWN (*Canad. Ent., 68 (1936), No. 4, pp. 88–91*).—These observations relate to three blowflies, *Wohlfahrtia vigil* Wlk., *Calliphora erythrocephala* Mg., and *Lucilia sericata* Mg. The two-striped grasshopper was reared in large numbers by the author from egg to maturity on a diet of whole lettuce heads alone.

Report of the Government entomologist, W. H. EDWARDS (*Jamaica Dept. Agr. Ann. Rpt., 1934, pp. 24–28*).—The occurrence of and work of the year with the more important insect enemies of sugarcane (particularly the sugarcane moth borer), citrus, banana, and other crops are briefly reported upon. Reference is made to the heavy infestation of Bombay mangoes by the fruitfly *Anastrepha longimacul* Greene.

Annual report for 1935 of the zoologist, C. WARBURTON (*Jour. Roy. Agr. Soc. England, 96 (1935), pp. 499–506, figs. 3*).—In this report a brief reference is made to some of the insect and related pests which have proved destructive to crops in England during 1935.

[Contributions on economic insects and insecticides] (*East Malling [Kent] Res. Sta. Ann. Rpt., 20 (1932), pp. 109–140, pls. 6; 21 (1933), pp. 176–242, 256–258, pl. 1, figs. 7*).—These resports (E. S. R., 68, p. 66) include the following contributions: Notes on Insect Pests and Mites in 1932 (pp. 109–116) and Further Observations on the Strawberry Tarsonemid Mite *Tarsonemus fragariae* Zimm. (pp. 117–131) (E. S. R., 66, p. 354), both by A. M. Massee; Two Apple Capsid [*Plesiocoris rugicollis* Fall.] Spraying Trials and Some Notes on Spray Damage, by W. Steer (pp. 132–140); Notes on Mite and Insect Pests for the Year 1933 (pp. 176–180) and Investigations on the Control of the Strawberry Tarsonemid Mite [*Tarsonemus fragariae* Zimm.] (pp. 181–187), both by A. M. Massee; Studies on *Byturus tomentosus* Fabr.—IV, 1933 Experiments on the Control of the Raspberry and Loganberry Beetle, by W. Steer (pp. 188–196) (E. S. R., 68, p. 648); Experiments on the Control of the Apple Sawfly *Hoplocampa testudinea* Klug.; The Results of One Season's Field Trials and Some Considerations Arising From Them, by G. L. Hey and W. Steer (pp. 197–216); An Experiment on the Control of the Apple Blossom Weevil *Anthonomus pomorum* (L.) Curt. by Means of a Derris Dust, by G. L. Hey, A. M. Massee, and W. Steer (pp. 217–219); A Progress Report on the Causes of Immunity to the Apple Woolly Aphis (*Eriosoma lanigerum* Hausmann), by R. M. Greenslade, A. M. Massee, and W. A. Roach (pp. 220–224); Some Notes on the Woolly [Apple] Aphis Parasite *Aphelinus mali* Hald., by R. M. Greenslade and A. M. Massee (pp. 225–227); Tortrix Investigations in 1933 (pp. 228–230) and Observations on the Effects of Various Gas Mixtures of Known Composition on Tortrix Larvae in Store (pp. 231–233), both by G. L. Hey and A. M. Massee; Miscellaneous Observations on Apple Sawfly (*Hoplocampa testudinea* Klug.) in 1933, by G. L. Hey and W. Steer (pp. 234–242); The Warm Water Treatment of Strawberry Plants, by A. M. Massee (pp. 256, 257); and Apple Sawfly [*Hoplocampa testudinea* Klug.]: Some Suggestions for Control Measures, by G. L. Hey, M. H. Moore, and W. Steer (p. 258).

The report for 1934 has been noted (E. S. R., 73, p. 643).

Insects injurious to cultivated plants: Their biology and control, II, A. BALACHOWSKY and L. MESNIL (*Les Insectes nuisibles aux plantes cultivées: Leurs moeurs, leur destruction. Paris: Étab. Busson, 1936, vol. 2, pp. XI+1139–1921, pl. 1, figs. 385*).—This second volume, which completes the work (E. S. R., 74, p. 367), takes up insect enemies of vegetable crops, forage legumes, and the Salicaceae, including willow, osier, and poplar (pp. 1141–1457); insects injurious to outdoor ornamental and decorative plants and greenhouse crops (pp. 1461–1620); polyphagous insect enemies of plant crops (pp. 1623–1710); insects injurious to stored grain and grain products (pp. 1713–1754); and insecticides (pp. 1757–1861). A bibliography (pp. 1865–1892) and a general index to the two volumes (pp. 1895–1921) are included.

[Contributions on economic insects] (*Rev. Path. Vég. et Ent. Agr. France, 22 (1935), No. 4, pp. 255–302, figs. 8*).—The Coccidae of Spain are dealt with by A. Balachowsky (pp. 255–269); the Coccidae of Morocco, by C. Rungs (pp. 270–283); observations on the spreading capacity of insecticide sprays, by J. de Francolini (pp. 284–287); the value of vegetable dusts in combating the Colorado potato beetle, by F. Robin (pp. 288–297); and the effect of arsenicals on the larvae of *Hyponomeuta padella*, by B. Trouvelot and M. Raucourt (pp. 298–302).

Entomological work, E. HARGREAVES (*Sierra Leone Dept. Agr. Ann. Rpt., 1934, pp. 16–18*).—The occurrence of and control work with economic insects during the year are briefly reported (E. S. R., 70, p. 61).

Report of the Government entomologist for 1934, H. HARGREAVES (*Uganda Dept. Agr. Ann. Rpt., 1934, pt. 2, pp. 62–72*).—The occurrence of and work of the year with important insect pests, particularly the resistance of cotton varieties to jassid bugs (*Empoasca* spp.), are reported (E. S. R., 72, p. 655).

Entomological investigations, G. A. JULIUS ET AL. (*Austral. Council Sci. and Indus. Res. Ann. Rpt., 9 (1935), pp. 28–34*).—The progress of investigational work with economic insects in 1934–35 (E. S. R., 73, p. 645) is reported upon.

[Report of work in entomology], A. F. BELL (*Queensland Bur. Sugar Expt. Stas. Ann. Rpt., 35 (1935), pp. 48–53*).—The occurrence of and work of the year with sugarcane insects in Queensland, particularly the grayback beetle (*Lepidoderma albohirtum* Waterh.) and the beetle borer, officially known as the New Guinea sugarcane weevil, are reported upon. The introduction of the giant toad (*Bufo marinus* L) from Hawaii, 102 in number, and their liberation at Meringa during the year is referred to.

Leaf miner and stem borer of tobacco in north Queensland, D. O. ATHERTON (*Queensland Agr. Jour., 45 (1936), Nos. 1, pp. 12–31, pl. 1, figs. 6; 2, pp. 131–145, figs. 7; 3, pp. 239–248; 4, pp. 331–344*).—This contribution relates to the potato tuber worm and the stem borer *Phthorimaea heliopa* Low., two of the most important enemies of tobacco in Queensland, their natural enemies, and means of control. A list of 59 references to the literature is included.

Injurious fruit insects during the past year, P. J. CHAPMAN (*N. Y. State Hort. Soc. Proc., 81 (1936), pp. 7–12*).—A practical contribution from the New York State Experiment Station on the status of injurious fruit insects in 1935.

[Contributions on apple insect control] (*Ill. State Hort. Soc. Trans., 69 (1935), pp. 167–199, 285, 286, 485–494*).—Contributions presented at the annual meeting of the society held at Decatur, Ill., in December 1935 (E. S. R., 73, p. 348) include the following: The Use of Nicotine in the Apple Spray Schedule, by W. P. Flint and M. D. Farrar (pp. 167–173), from the Illinois Experiment Station; The Spray Residue Situation, by W. A. Ruth and V. W. Kelly (pp. 174–188), with a Brief Summary of Some of the More Important New Experiments, by W. A. Ruth and D. S. Brown (pp. 186–188); A Grower's Results in Removing the Lead and Arsenical Load, by C. T. Smith (pp. 189–195); Apple Insect Control in Northern Illinois During 1935, by L. H. Shropshire (pp. 285, 286); and The Latest Methods of Fighting the Oriental Fruit Moth, by S. C. Chandler and W. P. Flint (pp. 485–492), from the Illinois Experiment Station.

Some insect problems of the small fruits, O. H. HAMMER (*N. Y. State Hort. Soc. Proc., 81 (1936), pp. 279–283*).—This is a practical contribution from the New York State Experiment Station, dealing with some of the more important currant, raspberry, and strawberry insects.

Observations on some insect enemies of the coffee tree [trans. title], J. V. LEROY (*Inst. Natl. Étude Agron. Congo Belge Pubs., Sér. Sci., No. 8 (1936), pp. 30, figs. 9*).—The pests here considered include leaf rolling moths of the genus *Epicampoptera*, particularly *E. marantica;* the coffee leaf miner (*Leucoptera coffeella* Guer.); the coffee berry beetle borer (*Stephanoderes hampei* Ferr.); and the coffee mealybug (*Pseudococcus lilacinus* Ckll.).

[Insect pests of lac host trees], P. M. GLOVER (*Indian Lac Res. Inst. Ann. Rpt., 1934–35, pp. 14–25*).—A brief account is given of the insects, particularly *Aspidiotus orientalis* Newst, attacking lac host trees, which, in the order of

severity attacked by *A. orientalis*, are *Zizyphus jujuba*, *Schleichera trijuga*, *Z. xylopyra*, and *Butea frondosa*. Observations of the predatory and parasitic enemies of lac and on control measures, both artificial and biological, follow. A brief account of the bionomics of *Laccifer lacca* (Kerr) is included.

Insects in aeroplanes: A brief report and suggestions, C. B. SYMES (*Kenya [Med. Dept.], Rec. Med. Res. Lab., No. 6 (1935), pp. 16, figs. 4; abs. in Rev. Appl. Ent., 24 (1936), Ser. B, No. 4, pp. 65, 66*).—Data and suggestions are given on some of the insect problems created in Kenya by air travel. After recording the distribution of the yellow-fever mosquito in Kenya, Uganda, and the Anglo-Egyptian Sudan, and of mosquitoes that have transferred yellow fever experimentally, tables are given which show the number of insects of different kinds caught in airplanes examined at Kisumu and Nairobi during various periods in 1933 and 1934 and in the hangar at Kisumu during the early part of 1934. In reference to control measures, it is pointed out that in spite of routine spraying of airplanes at various airports, insects are still being carried in serious numbers. Complete fumigation of an airplane with hydrocyanic acid gas can be carried out in 2 hr. or less with little if any inconvenience to traffic, but it is necessary to provide an effective means of dispersing the gas quickly and completely after fumigation. Promising results were obtained in two experiments carried out to test the efficacy for this purpose of an air blower consisting essentially of a large fan driven by a motorcycle engine to which was attached 30 ft. of canvas hose with a tin nozzle. Although fumigation will kill all insects in the airplane at the time, it will not prevent reinfestation, and should therefore be carried out as near the time of departure as possible. The airplanes should be made insect-proof and provided with insect-proof doors and windows that can be kept closed while in the airport. It is suggested that it be made compulsory to give warning of the intended arrival of aircraft (other than those regularly using airports), so that measures can be taken by health authorities to ascertain whether they are likely to be concerned in disease transmission.

Studies on the supercooling death of insects, K. SHIBATA (*Mem. Faculty Sci. and Agr., Taihoku Imp. Univ., 16 (1935), No. 2, pp. 91–103*).—This contribution, presented with a list of 11 references to the literature, deals with experimental work on the cold-death of the fruitfly *Chaetodacus cucurbitae* Coq., from which the conclusion is drawn that there are two cause groups, namely, freezing death and supercooling death.

"When the insects are exposed to low temperatures below the freezing point of their body fluid, they do not always freeze immediately but remain in a supercooling state, if the conditions of cooling are such as to keep them at a still state without being given mechanical shocks or such as to keep the rate of cooling slow. . . .

"The mechanism of death in the supercooling state is believed to be quite different from that due to freezing, for the time required to kill the insects from supercooling is far longer than that from freezing. All the larvae of a fruitfly, *C. cucurbitae*, are killed in 25 min. exposure when they are completely frozen at —3.4° C., in 20 min. at —5°, and in only 4 min. at —12°. On the contrary, as long as 16 hr. is necessary to kill them from supercooling at —3.4°, 8 hr. at —5°, and 2 hr. at —12°."

Studies on the death-temperature of a fruit-fly, Chaetodacus cucurbitae Coquillett, at the frozen state and the influence of supercooling upon its temperature, K. SHIBATA (*Mem. Faculty Sci. and Agr., Taihoku Imp. Univ., 16 (1935), No. 2, pp. 105–116, figs. 2*).—In the work reported it is shown that the body temperature of the fruitfly *C. cucurbitae* at which 100 percent mortality is produced owing to the freezing of the body fluid lies lower than —3.6° C.

(+25.2° F.). The depth of the supercooling as well as its duration has a marked effect upon the freezing death of the insect; that is, the deeper or the longer the supercooling, the higher is the death temperature of the fly.

The development of biological control of insect pests, with special reference to some current experiments, W. F. JEPSON (*Rev. Agr. Mauritius, Nos. 84 (1935), pp. 188–192; 85 (1936), pp. 29–34*).—The status of biological control work with insect pests is reported upon.

Choosing a spray program, P. J. PARROTT (*N. Y. State Hort. Soc. Proc., 81 (1936), pp. 18–26*).—This is a practical contribution from the New York State Experiment Station.

Insect control (*Rhode Island Sta. Rpt. [1935], p. 12*).—Reference is made to a comparison of insecticides for control of the cabbage root maggot.

The temperature and humidity relations of the cockroach.—IV, Thermal deathpoint, D. L. GUNN and F. B. NOTLEY (*Jour. Expt. Biol., 13 (1936), No. 1, pp. 28–34, figs. 4*).—In continuing earlier work (E. S. R., 73, p. 648), the thermal death points of three species of cockroaches in dry and in moist air have been determined for 1-day and 1-hr. exposures. Moist air has been found to be "more favorable than dry in the longer exposures, because in dry air death occurs from desiccation when the temperature itself is not fatal. Dry air is more favorable than moist in the shorter exposures, owing to the fact that the evaporation of water lowers the body temperature. Bearing in mind the thermotactic behavior of these animals, these observations would seem to have little ecological importance."

A general investigation of locust outbreaks in China during the year 1934, F. C. Woo and T. S. CHENG ([*China*] *Natl. Agr. Res. Bur. Spec. Pub. 10 (1935), pp. 32, pl. 1, figs. 4; Eng. abs., pp. 31, 32*).—A compilation of reports from seven provinces represented at a conference in the interest of grasshopper control, received every 10 days from the time of the meeting in early June until November, is here presented. The account relates to the two principal species of migratory grasshoppers in 1934, namely, the so-called migratory locust *Locusta migratoria* L. and the bamboo locust *Ceracris kiangsu* Tsai, with information on prevalence, damage, control measures, etc.

A general investigation of the locust (Locusta migratoria L.) outbreaks in China during the year 1933, F. C. Woo and T. S. CHENG ([*China*] *Natl. Agr. Res. Bur. Spec. Pub. 5 (1934), pp. 42, figs. 6; Eng. abs., pp. 41, 42*).—Migratory grasshopper outbreaks in 265 hsiens in 9 provinces of China in 1933 are reported upon.

The apple thrips Thrips imaginis Bagnall in South Australia, J. DAVIDSON (*Jour. Dept. Agr. So. Austral., 39 (1936), No. 7, pp. 930–939, figs. 4*).—Following a brief introduction, a description is given of *T. imaginis*, its life history, food plants, fluctuations in numbers throughout the year, and control measures.

The gladiolus thrips—causes growers severe losses, N. S. NOBLE (*Agr. Gaz. N. S. Wales. 46 (1935), No. 12, pp. 681, 682, fig. 1*).—The gladiolus thrips, first recorded as a pest in New South Wales in 1932, is said to have caused severe injury to commercial gladiolus crops and private gardens.

Thrips attacking man, S. F. BAILEY (*Canad. Ent., 68 (1936), No. 5, pp. 95–98*).—The literature relating to the attack of man by thrips is briefly reviewed, and personal observations are referred to.

Frankliniella gossypiana, new name, J. D. HOOD (*Biol. Soc. Wash. Proc., 49 (1936), p. 68*).—The name *F. gossypiana* is proposed as a substitute for *Euthrips gossypii*, as *E. gossypii* has been used for quite a different insect occurring in Formosa. It is pointed out that this thrips is not restricted to cotton as a food plant.

The biological control of Clidemia hirta in Fiji, R. V. FYFE (*Jour. Austral. Inst. Agr. Sci., 2 (1936), No. 1, pp. 8, 9*).—The plant *C. hirta* was introduced into Fiji from British Guiana sometime prior to 1800 and became a major weed pest through invading permanent cultivations and native forests. It is said to have been checked by the combined effect of competing vegetation and a number of insect enemies, chief of which is the thrips *Liothrips urichi*, introduced from Trinidad and liberated on the island of Viti Levu, Fiji, in 1930.

Experimental studies on the influence of low temperatures upon the tropical bed-bug (Cimex hemipterus Fabricius), N. OHMORI (*Taiwan Igakkai Zasshi (Jour. Med. Assoc. Formosa), 35 (1936), No. 3, pp. 624–644, fig. 1; Eng. abs., pp. 642–644*).—This is a third report of experimental studies on the influence of low temperatures on the tropical bedbug *C. hemipterus*, conducted in the attempt to explain experimentally the geographical distribution of the pest.

The rôle of bedbugs (Cimex lectularius L.) in transmission and preservation of tularaemia virus, V. P. BOZHENKO (BOGENKO) (*Vest. Mikrobiol., Épidemiol. i Parazitol. (Rev. Microbiol., Épidémiol. et Parasitol.), 14 (1935), No. 4, pp. 436–440; Eng. abs., p. 440*).—Transmission of tularemia by the bites of infected bedbugs was detected 15 hr. after the infecting feed. The virus was present in the bugs more than 6 mo., it having been recovered from feces of the infected insects. It remained virulent in the body of the bedbug for as long as 136 days after feeding.

Potato psyllid control, G. HARTMAN (*Wyoming Sta. Bul. 217 (1936), pp. 24, figs. 3*).—The results of a year's study of the potato psyllid *Paratrioza cockerelli* Sulc., which has caused heavy losses in potato production in Wyoming in the last few years, are reported.

In control work two applications of lime-sulfur solution at the right time have given larger net returns than one and as large or nearly as large as three. The best time of application appeared to be the early bloom stage for the first, and from 15 to 17 days later for the second. On dry land the lowest net return from two applications was $4.95 per acre and the highest $24.75. On irrigated land the lowest was $16.91 and the highest $32.89. When potato psyllids are present in a potato field, the use of lime-sulfur is profitable. The first spray should be applied at about the time the plants begin to bloom, followed 2 to 3 weeks later with a second application. Lime-sulfur sprayed on the vines using a pressure of 300 lb. per square inch gave better control than lower pressures.

"To date, there is no indication that the symptoms produced upon potatoes by the action of the psyllids are in any way carried from one season to the next by seed tubers from infested fields. The disease occurs only when psyllid nymphs are found upon the vines. . . .

"It appears now that spraying of potatoes for psyllid control is advisable and may become necessary for profitable potato production. The added cost of spraying will make it all the more necessary to give the utmost attention to all the factors which contribute to successful potato production. Such factors as land selection and preparation, the use of good seed, the proper planting date, better cultural methods, crop rotation, etc., must be carefully studied and practiced."

Stomach poisons such as zinc arsenite and lead arsenate may be mixed with the lime-sulfur solution for the control of chewing insects such as beetles and leafhoppers.

Transmission of sugarcane mosaic by the rusty plum aphid (Hysteroneura setariae), J. W. INGRAM and E. M. SUMMERS (*Jour. Agr. Res. [U. S.],*

52 (1936), No. 11, pp. 879–887).—In preliminary experiments commenced in Louisiana in 1933, here reported, the rusty plum aphid transferred mosaic to 24 of 419 healthy sugarcane plants. In parallel experiments, the corn leaf aphid transferred mosaic to 17 of 72 healthy plants. The rusty plum aphid has been found in the State feeding on sugarcane plants throughout the year, usually on the collar lobe, and is the most abundant of the aphids found on sugarcane in that State. It occurs on many different species of grasses growing in and around sugarcane fields, some of which are subject to mosaic. The green bug transferred the mosaic in two instances in preliminary trials.

Capitophorus aphids infesting Chrysothamnus, G. F. KNOWLTON and C. F. SMITH (*Canad. Ent., 68 (1936), No. 5, pp. 107–113, figs. 2*).—In this contribution from the Utah Experiment Station, 12 species are recorded as infesting rabbitbrush in western North America, of which 6 are described as new to science. A key for the identification of the aptera is included.

A primer for the aphid hunter, F. C. HOTTES (*Biol. Soc. Wash. Proc., 49 (1936), pp. 27–36*).—The technic employed in work with the Aphididae, including collecting equipment, habitat and manner of collection, manner of mounting for study and preservation, etc., is presented.

The symbionts of Pseudococcus brevipes in relation to a phytotoxic secretion of the insect, W. CARTER (*Phytopathology, 26 (1936), No. 2, pp. 176–183, figs. 2*).—This contribution from the Hawaiian Pineapple Canners' Experiment Station (E. S. R., 69, p. 829) reports upon studies of the relationship between the symbionts of the pineapple mealybug and the phytotoxic secretion of the insect responsible for green spotting of pineapple leaves. Colonies of this mealybug were transferred from pineapple to panicum grass (*Panicum barbinode*) and transferred back to pineapples after varying lengths of time.

"The effect of the colonies' feeding on the grass was to eliminate the green-spotting capacity of the mealybugs; continued growing of these colonies on pineapple has failed to restore this capacity. Coincident with the loss of the green-spotting capacity is the disappearance of the rodlike symbiont from the mycetome of the insect. The evidence is that this symbiont is pleomorphic and passes from a rod-shape to a coccus-rod form under the influence of radically changed nutrition. The rod-shape form is invariably present in green-spotting mealybugs, the coccus-rod in nongreen-spotting mealybugs. The fact that return of the mealybugs to pineapple does not result in the return of the capacity to produce green spots is proof that the loss of this capacity in the first instance is not due merely to a changed food plant, but to a radically changed physiology that is clearly associated with pleomorphism of the insect's symbionts."

Notes on Pseudococcinae of economic importance in Brazil, with descriptions of four new species [trans. title], E. J. HAMBLETON (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 105–120, pls. 3, figs. 15; Eng. abs., p 119*).—Notes are given on the life history, occurrence, and host plants of 18 species of mealybugs from Brazil, several of which are serious pests in other parts of the world. *Pseudococcus magnoliae* on *Magnolia grandiflora* (Magnoliaceae), *P. mamabilis* on *Cupressus glauca* (Coniferae), *P. tibouchinae* on *Tibouchina mutabilis* (Melastomaceae), and *P. sociabilis* from *Hedera helix* (Araliaceae) and *Erythrina recticulata* (Leguminosae) are described as new to science.

The comparative insecticidal efficiency against the camphor scale of spray oils with different unsulphonatable residues, A. W. CRESSMAN and L. H. DAWSEY (*Jour. Agr. Res. [U. S.], 52 (1936), No. 11, pp 865–878, figs. 3*).—A report is given of a comparative study of the insecticidal value of three petroleum oils with 6, 16, and 33 percent by volume of sulfonatable material in laboratory and field spraying tests. The oils were applied in the form of emulsions containing from 0 9 to 2 percent of oil, sodium oleate soap being

used as the emulsifier, to camphor-tree plants and trees infested with the camphor scale. The other characteristics of the different oils were substantially the same, so that any detectable difference in scale mortality could be due only to differences in the sulfonatable portions.

Analyses of the oil deposits left by sprays showed that the deposits were independent of the sulfonatable content of the oil but varied directly with the oil content of the spray. When sprays which gave equal oil deposits were compared, the variations in insect mortality appeared to be entirely random, and no differences were found which could be attributed to the sulfonatable content of the oils.

Entomological investigations on the spike disease of sandal (26) Coccidae (Homopt.), N. C. CHATTERJEE and T. V. R. AYYAR (*Indian Forest Rec., n. ser., 1 (1936), No. 12, pp. [2]+233–242*).—Twelve species of Coccidae frequenting the foliage of sandal (*Santalum album* Linn.) in south India are listed. The results of field experiments are said to eliminate the Coccidae as possible disseminators of the spike disease. (See E. S. R., 75, p. 79.)

The control of the red scale in Palestine, M. H. SACHS (*Hadar, 8 (1935), Nos. 7, pp. 197, 198, 201–204; 8–9, pp. 234–240*).—It is concluded that spraying with lubricating oils is not an adequate means of control where the infestation is heavy, and that in heavy infestations of the red, black (Florida red), and mussel (purple) scales, only fumigation will be satisfactory, unless biological control is made effective.

The Florida wax-scale (Ceroplastes floridensis Comst.) in Palestine, F. S. BODENHEIMER (*Hadar. 8 (1935), No. 8–9, pp. 223, 224, 227, 228, figs. 2*).—A continuation of this contribution (E. S. R., 74, p. 669).

A study of codling moth collection and emergence, T. J. HEADLEE (*New Jersey Stas. Bul. 605 (1936). pp. 24, figs. 3*).—Continuous records of codling moth emergence at Glassboro, N. J., from the middle of the summer season of 1926 to the end of the summer season of 1935 are presented, of which the following interpretation has been made:

"Period from full bloom to codling moth emergence is so variable that it seems impracticable to use full bloom or blossom fall as a satisfactory datum point for dating sprays for control of codling moth. Because of the reasonably constant relation of date of maximum emergence (when one-half the total emergence has occurred) of moths to larval entry in apples, the date of maximum emergence is considered the best datum point from which to date cover sprays for control. Because of the time required for dissemination of recommendations to growers, the date of maximum emergence must be predicted from 1 to 2 weeks in advance for each climatically different area.

"These predictions are made by (1) plotting codling moth emergence observed at the codling moth emergence box station time and plotting temperature accumulations, also against time, at each temperature station, including the one located at the box station; (2) projecting the curve of codling moth emergence in its apparently normal direction to the calculated number, which is one-half of what will emerge, and noting the date; (3) projecting the curve of temperature accumulation at this same notation to the date of prediction for maximum emergence and noting the temperature accumulations on that date; (4) projecting the curves of the other temperature stations to a point where temperature accumulation is the same as that at the box station; (5) taking these dates as the date of maximum emergence in each case; [and] maintaining the bait pan records at the box stations and as an evaluation of the importance of the early emerging fringe.

"The variations of the total and partial length of codling moth brood are so large as to preclude their genesis from error and to indicate they are due to

environmental factors. The codling moth broods of different localities consist of a dominant group of the same length of cycle and of subsidiary groups having much shorter and much longer cycles. The dominant group gives the name of brood condition to the area. The codling moth is shown by these studies never to winter over in the pupal stage. Mortality in the emergence boxes is about 29.1 percent. About one-half the individuals that will emerge come out in the late summer and about one-half in the subsequent spring. Temperatures to which the codling moth larvae are subjected in the summer when they are collected do not appear to influence their emergence during the subsequent spring. The accumulation of the thermal constant, therefore, properly begins with January 1. Only a limited and almost negligible accumulation takes place prior to April 1."

New developments in summer oil sprays and their use for codling moth control, C. R. CLEVELAND (*Mich. State Hort. Soc. Ann. Rpt., 65 (1935), pp. 91–111*).—Tests in orchards in 1934 and 1935 (Kansas to Michigan), the details of which are given in tables, have shown that a combination of the commercial brand Superla Summer Spray Oil (one of the so-called new emulsible or soluble oils) with lead arsenate and lime can be used under average Michigan conditions as many as three times. The use of as much as 0.75 percent of Superla and lead arsenate 3 lb. and lime 3–5 lb. per 100 gal. in each application produces definite improvement in codling moth control without failing to meet the lead residue tolerance, if the fruit is washed at room temperature in low strength hydrochloric acid and modern underbrush machines such as are being installed at fruit exchanges are employed.

How the 1934 drouth affected the codling moth life cycle, M. H. SWENK (*Nebr. State Bd. Agr. Ann. Rpt., 1935, pp. 555–563, fig. 1*).—This report on an intensive study of the broods of the codling moth in southeastern Nebraska, with special reference to the responses of the insect to varying meteorological conditions, represents the seventh season in which the work has been conducted by the Nebraska Experiment Station. A diagram of the life history at Lincoln in 1934 is included.

Oriental fruit moth investigations in Ohio, II, R. B. NEISWANDER (*Ohio Sta. Bul. 569 (1936), pp. 30, figs. 7*).—This second contribution (E. S. R., 64, p. 362) reports upon biological studies (pp. 3–12), control studies with insecticides (pp. 13–17), parasites and their utilization in control (pp. 17–28), and the present status of the oriental fruit moth in Ohio (pp. 28, 29).

The time of emergence of spring brood oriental fruit moths was found to vary with the temperature but to correspond with the blooming period of the peach, both occurring successively later in a definite progression across the State from southern Ohio northward.

"In cultivated peach orchards in Ohio considerable numbers of both winter and summer cocoons have been found on the ground. Therefore orchards in which frequent cultivation is practiced have an advantage over those which are not tilled. On the other hand, the fact that some of the fruit moth parasites attack weed-infesing larvae should be borne in mind. Packing houses and used baskets frequently harbor many hibernating larvae, and these should be given attention during periods of fruit moth abundance.

"In Ohio orchards fruit moth larvae have been found feeding in the fruits of peach, apple, quince, pear, and plum and in the twigs of peach, apple, and sweet cherry. They have also been found in the growing tips of a rose bush.

"Larval mortality varies with the hardness of the peach fruit in which the larvae feed. Natural mortality is low early in the season when the peach is growing rapidly, high in midseason while the stone is hardening, and low again when the peach swells rapidly before ripening.

"Eight infestation counts made in a particular orchard during three successive seasons have shown an unequal but consistent fruit moth distribution across the orchard. One side was consistently most heavily infested. Such peculiar distributions have not been adequately explained.

"In experimental spraying work a combination of summer oil and nicotine has uniformly given best results. Five applications made to quinces during the latter part of the season produced a large percentage of marketable fruit in 1935; whereas unsprayed quinces in the immediate vicinity were almost a total loss. Experience has shown that any spraying program for fruit moth control must be timed with precision if the greatest good is to result.

"Approximately 25,000 individuals of *Macrocentrus ancylivorus* have been released in Ohio. This parasite species has been multiplying rapidly in northern Ohio and has been largely responsible for a significant reduction in fruit moth injury in that part of the State. Eight species of foreign parasites have been introduced into Ohio, but as yet none are known to have become established. Native parasite species and other natural enemies have become sufficiently abundant in central and southern Ohio to suppress the fruit moth population. Several of the more important fruit moth parasites are known to attack the ragweed borer [*Epiblema strenuana* Walk.] and the strawberry leaf roller, both of which are generally distributed in Ohio. These parasites, therefore, should be able to survive during periods when fruit moth larvae are scarce."

Laspeyresia molesta Busck and its Argentine parasites [trans. title], U. L. CRISTOBAL (*Rev. Facult. Agron. La Plata, 3. ser., 20 (1935), No. 2, pp. 140–169, figs. 21*).—An account of the oriental fruit moth, its biology and injury to the fruit, is followed by information on its natural control, including four parasites encountered in La Plata, namely, *Eudeleboea lopezi* Blanch., *Pimpla behrensiella* Blanch., *Hemiteles venturi* Sch., and *Tyroglyphus* sp. A list is given of 19 references to the literature consulted.

The pea moth (Laspeyresia nigricana Steph.), A. J. HANSON and R. L. WEBSTER (*Washington Sta. Bul. 327 (1936), pp. 22, pls. 6, figs. 5*).—Studies of the pea moth, which in 1928 first appeared as a pest of economic importance in Washington in the Nooksack Valley, Whatcom County, some 12 miles south of the British Columbia line, and became a problem in the Skagit flats of the Mount Vernon district in 1933, are reported upon. The nature of its injury, distribution, life history, description of the stages, host plants, planting dates and varieties, quarantine regulations, soil experiments, value of insecticides, parasites, and the control program are dealt with, the details being given in five tables.

The European corn borer in Indiana, G. A. FICHT (*Indiana Sta. Bul. 406 (1936), pp. 24, figs. 18*).—A practical account of the European corn borer as it occurs in Indiana, with control measures applicable in that State.

An insect injuring sunflowers in Manitoba, R. D. BIRD and W. R. ALLEN (*Canad. Ent., 68 (1936), No. 4, pp. 93, 94*).—The pyralid moth *Homoeosoma electellum* Hlst. is a source of injury to sunflowers in Manitoba through its attack upon the heads, leaves, and stalks. Its life cycle, which includes four larval instars, is completed in 30 days.

Studies in enzymatic histochemistry.—XVI, The digestion of keratin by the larvae of the clothes moth (Tineola biselliella Humm.), K. LINDER-STRØM-LANG and F. DUSPIVA (*Compt. Rend. Lab. Carlsberg, Sér. Chim., 21 (1936), No. 4, pp. 53–82+[1], pl. 1, figs. 2*).—This contribution is presented with a list of 21 references to the literature.

Life-histories of some Indian Thyrididae (Lepidoptera), B. B. BOSE (*Indian Jour. Agr. Sci., 5 (1935), No. 6, pp. 737–742, pls. 3*).—The pyralidid moth

Betousa stylophora Swinh., which is of economic importance through its formation of galls on *Phyllanthus emblica*, is reported upon at some length. A brief account is also given of *Rhodoneura loceusalis* Wlk., which feeds on the leaves and bores tender top shoots of *Loranthus longiflorus* at Pusa, and several additional species are noted.

A list of Lepidoptera (Heterocera) from the State of Minas Geraes [trans. title], E. J. HAMBLETON and W. T. M. FORBES (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 213–256; Eng. abs., p. 256*).—A list of 1,445 species of Heterocera occurring in the State of Minas Geraes arranged by families and subfamilies is presented.

How surgical maggots act, L. E. W. BEVAN (*Vet. Rec., 16 (1936), No. 18, pp. 567, 568, 569*).—It is suggested that the manner in which surgical maggots act is not through their generating a ferment but by infecting the wounds with micro-organisms producing proteolytic ferments and other substances which stimulate cell reproduction and hasten resolution. These substances can be reproduced in bulk by in vitro culture of the micro-organisms which generate them.

The bactericidal element of dipterous larvae (myiases of wounds and myiases of fruits) [trans. title], C. PICADO (*Bul. Biol. France et Belg., 69 (1935), No. 4, pp. 409–438, figs. 3*).—It is concluded that the bactericidal element of larvae in myiases does not preexist but is elaborated in the intestines of larvae infesting the wounds and of those infesting fruits when the food is suitable. The bacterial flora of the flesh in putrefaction plays a preponderant role in the elaboration of bactericidal substances. Under an acid condition, maggots in fruit also have been found to elaborate intestinal substances that are bactericidal for staphylococci.

A list is given of 20 references to the literature.

Observations and experiments on the blow-fly (Calliphora erythrocephala) during the first day after emergence, G. FRAENKEL (*Zool. Soc. London Proc., 1936, IV, pp. 893–904, figs. 2*).—Observations on the digging, inflation of the body and expansion of the wings, first filling of the air sacs, and coloration are reported upon, with a list of 16 references to the literature.

The transmission of yaws from man to rabbits by an insect vector, Hippelates pallipes Loew, H. W. KUMM and T. B. TURNER (*Amer. Jour. Trop. Med., 16 (1936), No. 3, pp. 245–271, figs. 5*).—The experiments reported have demonstrated that yaws can be transmitted from man to rabbits by *H. pallipes*, and it is thought probable that this also takes place in transmission from man to man.

Control of fruit fly: Experiments with white oil-nicotine sulphate spray, J. A. WRIGHT (*Agr. Gaz. N. S. Wales, 46 (1935), No. 12, p. 689, fig. 1*).—Control work with *Chaetodacus tryoni* Frogg. indicates that a white oil-nicotine sulfate mixture effects a considerable reduction in infestation by this fruitfly.

Notes on the autecology of some fruit-flies.—I, On the melon-fly, K. KOIDSUMI and K. SHIRATA (*Jour. Soc. Trop. Agr. (Nettai Nôgaku Kwaishi), 7 (1935), No. 3, pp. 245–254*).—This contribution in Japanese deals with the melonfly.

Flies as household pests in Iowa, C. H. RICHARDSON (*Iowa Sta. Bul. 345 (1936), pp. 215–238, figs. 13*).—A practical account of the common species of flies that find their way into the home and procedures for their control.

The effect of desiccation on survival and metamorphosis of the Japanese beetle (Popillia japonica Newman), D. LUDWIG (*Physiol. Zool., 9 (1936), No. 1, pp. 27–42, fig. 1*).—The rate at which different stages of the Japanese beetle become desiccated, under approximately identical environmental

conditions, has been found to decrease in the following order: First-, second-, third-instar larvae, late prepupae, early prepupae, and pupae.

"The maximum fatal limits of desiccation, expressed in weight and as percentage of original weight, varied as follows: Second-instar larvae, 45 percent; first- and third-instar larvae, 50 percent; early prepupae, 56 percent; late prepupae, 66 percent; and pupae, 69 percent. When expressed in terms of water content, the variations were greatly reduced, as shown by the following figures: Third-instar larvae, 62 percent; early prepupae, 59.1 percent; late prepupae, 63.4 percent; and pupae, 65.9 percent.

"The water content of the adult beetle is approximately the same (66–88 percent) regardless of whether it had been previously desiccated in the prepupal or the pupal stages. Water content is restored by a loss of less water at the time of emergence. When larvae are desiccated, water content is restored before development can proceed.

"The prepupal and pupal stages contain more water than is necessary for normal metamorphosis. Pupae can be desiccated until they lose about one-half of the water normally lost at the time of emergence and still emerge normally.

"The duration of the pupal stage is increased by desiccation of either the prepupal or pupal stages. This increase is inversely proportional to the water content of the pupae."

Japanese beetle (Popillia japonica), T. J. HEADLEE (*New Jersey Stas. Circ. 367 (1936), pp. 8, figs. 2*).—A practical account of this beetle.

Japanese beetle control in commercial fruit plantings, T. J. HEADLEE (*New Jersey Stas. Circ. 366 (1936), pp. 7*).—A practical account of control measures for this pest in New Jersey.

Notes on the "flat wireworm" Aeolus mellillus Say, G. M. STIBBETT (*Canad. Ent., 68 (1936), No. 5, pp. 117, 118*).—This wireworm, which has been collected in various parts of Canada but is only sufficiently abundant in southern Ontario, west and south of London, to be of economic importance, has increased in injuriousness from 1930, when it injured tobacco at Charing Cross, Ontario. The important crops thus far damaged include tobacco, corn, and sugar beets.

The bionomics and control of wireworms in Maine, J. H. HAWKINS (*Maine Sta. Bul. 381 (1936), pp. [4]+146, pls. 13, figs. 19*).—The results of studies of wireworms extending over a period of several years are reported upon. An introductory account in which the economic importance of wireworms, food plants of larvae, distribution, a list of the Maine Elateridae, and the morphology and biology of the wheat wireworm are dealt with (pp. 14–50), is followed by accounts of the genera *Melanotus*, *Ludius*, *Limonius*, *Cardiophorus*, and *Athous* and notes on *Ludius cylindriformis* Hbst., *Cryptohypnus abbreviatus* Say, *Oestodes* sp., and *Hemicrepidius decoloratus* Say. Discussions of millepedes sometimes mistaken for wireworms, the ecology of elaterid larvae with special reference to wireworm abundance, wireworm injury to plants, a wireworm census, control measures, nematode parasites of adults of the wheat wireworm, fungi in relation to wireworms, and predaceous enemies of wireworms are then presented.

The life history of the wheat wireworm requires at least 3 yr. for its completion, and some larvae do not pupate until August of the fourth year. The life histories of other species are imperfectly known.

Cultivation was found to be a practical method of controlling wireworms. It required from 1 to 4 yr. to reduce the wireworm population to a point consistent with the safe production of susceptible crops. The time required to

control wireworms by cultivation depended upon the initial infestation. Approximately 45 percent of the wireworm population was found to be eliminated by 1 yr. of cultivation, 65 percent by 2 yr., and 80 percent by 3 yr. of continuous cultivation of the soil. Clean cultivation was also found essential to wireworm control. The wireworm population was apparently but little more reduced in soil kept fallow than it was in soil in which cultivated crops were grown.

Baits of clover, cut and placed on the soil, were the most attractive of those used for beetles of the wheat wireworm. Poisons added to baits for the adults also acted as repellents in most cases. Beetles of *C. abbreviatus* were attracted to baits of graham flour dough.

The most important parasite of the wheat wireworm found was a nematode, *Hexamermis* sp. This parasite lives in the body of the beetle and apparently prevents the eggs of the host from becoming fully developed.

A list of 85 references to the literature is included.

On some parasites found in association with the stem weevil pest of cotton in south India (Pempheres affinis, F.) and their role in its biological control, T. V. R. AYYAR and V. MARGABANDHU (*Madras Agr. Jour., 24 (1936), No. 8, pp. 102–107*).—Notes are presented on parasitic insects commonly associated with the stem weevil enemy of cotton in south India.

A cluster of bees, T. RAYMENT (*Sydney: Endeavour Press, 1935, pp. 752, pls. [8], figs. [205]*).—The first part of this work, to which the introduction is by E. F. Phillips, consists of 60 essays on the life history of Australian bees. Part 2 (pp. 635–743) consists of descriptions of over 100 new species and subspecies, representing the families Hylaeidae, Colletidae, Melectidae, Andrenidae, Anthrophoridae, Megachilidae, Xylocopidae, Ceratinidae, Apidae, Ichneumonidae, Thynnidae, and Phloeothripidae.

Disease resistance and American foulbrood, O. W. PARK (*Amer. Bee Jour., 76 (1936), No. 1, pp. 12–15, figs. 13*).—Work at the Iowa Experiment Station led to the conclusion that variation in resistance to American foul brood does exist in honeybees, marked resistance having been demonstrated by several colonies.

Tetrastichus brevistigma, new species (Hymenoptera: Eulophidae), A. B. GAHAN (*Ent. Soc. Wash. Proc., 38 (1936), No. 4, pp. 76, 77*).—A parasite reared from pupae of the elm leaf beetle at Middleboro and Woburn, Mass., is described as new under the name *T. brevistigma*.

The morphology and biology of Anastatus [Hym. Chalcididae] parasites of the oothecae of mantids [trans. title], F. BERNARD (*Bul. Soc. Ent. France, 41 (1936), No. 5, pp. 69–75, fig. 1*).—The author reports that the oothecae of small Mediterranean mantids of the genus *Ameles* are abundantly parasitized by two chalcids of the genus *Anastatus*, namely, *A. amelcophagus*, a very common parasite, and *A. picardi* n. sp., rarely met with.

Heterospilus coffeicola Schmied., parasite of the coffee berry borer Stephanoderes hampei (Ferr.) [trans. title], S. DE TOLEDO PIZA, JR., and J. PINTO DA FONSECA (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 179–199, pl. 1, figs. 12; Eng. abs., p. 199*).—A contribution to the biology of *H. coffeicola*, a hymenopterous parasite, which feeds on the eggs of *S. hampei*, is presented. "The feeding activities of this parasite are confined to those fruits in which primary infestation has occurred. In fruits of secondary infestation by the coffee berry borer, *H. coffeicola* fails to develop. *H. coffeicola* can only survive in regions where coffee production occurs throughout the entire year. In order that this insect may become an effective agent in the control of the coffee berry borer in Brazil, it would be necessary to maintain permanent infestations of the borer in the open air."

Sawfly biologies.—I, Neodiprion tsugae Middleton, G. R. HOPPING and H. B. LEECH (*Canad. Ent., 68 (1936), No. 4, pp. 71–79, figs. 2*).—A study of the biology of the western hemlock sawfly *N. tsugae*, which injured hemlock over an area of 40 sq. miles on Queen Charlotte Islands, British Columbia, in 1931, is reported upon. In 1932 the outbreak showed definite signs of subsiding and had practically disappeared by 1933. Many trees were killed during the peak year of 1931, indicating that this is a primary enemy of western hemlock and that outbreaks may be expected from time to time in the Pacific Northwest. There is said to be a single generation of this sawfly, which hatches out in May, the larvae feeding through June and spinning up through July and early August. Five hymenopterous parasites were reared from the larvae or pupae, namely, *Delomerista* sp., *Phaeogenes hariolus* Cress., *P. articus* Cush., *Pezoporus* sp., and *Olesicampe* sp.

The tomato mite (Phyllocoptes lycopersici Tryon.), W. L. MORGAN (*Agr. Gaz. N. S. Wales, 46 (1935), No. 12, pp. 683, 684, figs. 3*).—The tomato mite, first recorded in Queensland in 1917 from tomatoes, has seriously damaged this crop in the greenhouse since its appearance near Sydney in 1929.

Notes on the occurrence and host relationships of the tick Ornithodoros talaje in Arizona, G. M. KOHLS and R. A. COOLEY (*Pub. Health Rpts. [U. S.], 51 (1936), No. 17, pp. 512, 513*).—This tick transmitter of relapsing fever, the bite of which is very painful to man, is reported to have been collected in the larval stage from the kangaroo rat (*Dipodomys* sp.) in the vicinity of Aguila, Ariz. Nymphs and adults were found in soil from the kangaroo rat burrows.

Ornithodoros parkeri, a new species on rodents, R. A. COOLEY (*Pub. Health Rpts. [U. S.], 51 (1936), No. 15, pp. 431–433, pl. 1*).—The name *O. parkeri* is given to a new tick collected from rodents in Wyoming and Washington, including ground squirrels (*Citellus* sp.), a jack rabbit, a cottontail rabbit, and a prairie dog.

The black widow spider rare in Michigan, R. HUTSON (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, p. 247*).—A brief practical description of *Latrodectus mactans* Fab.

ANIMAL PRODUCTION

[Livestock investigations in Alaska] (*Alaska Col. Sta. Bul. 4 [1935], pp. 29–36, 42–44, figs. 5*).—Preliminary results are reported on crossing mountain sheep with domesticated sheep, by L. J. Palmer; and the development of a hardy strain of dairy cattle by crossing the Holstein and Galloway breeds at the Matanuska Substation, by D. L. Irwin, including milking records.

[Investigations with livestock in Indiana] (*Indiana Sta. Rpt. 1935, pp. 19–23, 50–52, figs. 2*).—Results obtained in tests with beef cattle are reported on tankage for fattening cattle, finishing cattle without corn, comparative cost of wintering wet cows and dry cows, spring v. fall calves, native v. western calves, and heifer v. steer calves for beef production.

Swine tests yielded information on the effect of soybeans and soybean products on the quality of pork, the nutritive value and mineral deficiencies of soybeans and soybean products, the value of heated water for swine, the value of soybeans for brood sows, local and terminal market price differentials, and the influence of feeding at market on the warm dressing yield of hogs.

Results are noted from 25 yr. of lamb feeding, feeding lambs without hay, tankage as a protein supplement, pasture for lambs, shearing native lambs, grain for young lambs, and feeding twin lambs.

In poultry studies data were obtained on marketing eggs under U. S. grades and on a graded basis, inheritance of rate of growth, wheat and oats as substitutes for bran and middlings in broiler rations, reduction of protein in rations

for chicks, soybean oil meal in broiler rations, amounts of corn in laying rations, condensed buttermilk for laying pullets, poultry housing, feeding of turkeys, and meat scrap and dried milk in rations for young ducks.

[Livestock investigations in Tennessee], M. JACOB (*Tennessee Sta. Rpt. 1934, pp. 9–13*).—Results obtained in tests with beef cattle are reported on the effect of adding dicalcium phosphate to a ration of cottonseed meal and corn-and-sorghum silage for fattening 2-year-old steers, the amount of grain necessary to feed 2-year-old steers being finished on grass at the Middle Tennessee Substation, a comparison of ground shelled corn and cottonseed meal v. cottonseed meal alone as concentrates for feeding calves, and the amount of grain necessary for the most economical finishing of baby beeves at the West Tennessee Substation.

A comparison was made of the value of alfalfa, bluegrass, sweetclover, lespedeza, and other grazing crops for fattening pigs fed corn and tankage at the Middle Tennessee Substation.

In sheep studies, information was obtained on the value of supplemental feeds for early spring lambs finished on pasture and on breeds of sheep most suitable for Tennessee.

Mineral requirements of animals (*U. S. Dept. Agr., Bur. Anim. Indus., Anim. Husb. Div., 1936, A. H. D. No. 17, rev., pp. 3*).—The need of adding minerals to the rations of livestock is discussed. In addition, lists are given of feeding stuffs and inorganic minerals rich in calcium and phosphorus. The mineral content of some of the more common feeds is given in table form.

Sulphur metabolism.—I, The absorption and excretion of flowers of sulphur, J. H. KELLERMANN (*Onderstepoort Jour. Vet. Sci. and Anim. Indus., 4 (1935), No. 1, pp. 199–228*).—In metabolism tests with both rats and sheep, it was demonstrated that both absorption and excretion of inorganic sulfur occurred at a very slow rate. From 11 to 12 days was required for the inorganic sulfur of the urine to return to normal after sulfur feeding was discontinued, apparently due to the storage of sulfur in the animal body and also to long retention of sulfur in the digestive tract. Elemental sulfur was less readily absorbed than food sulfur, the absorption of the former occurring in adverse proportion to the concentration of the latter in the diet. On this basis, the greater the concentration of food sulfur in the diet, the higher will be the toxic level of elemental sulfur.

The daily ingestion of 5 g of inorganic sulfur had no deleterious effect on sheep, while the addition of 1 percent of sulfur to the basal ration was definitely toxic to rats. The rate of absorption was 28.13 percent for the sheep and 38 percent for the rats.

The composition and digestibility of mung-bean silage, with observations on the silica-ratio procedure for studying digestibility, W. D. GALLUP and A. H. KUHLMAN (*Jour. Agr. Res. [U. S.], 53 (1936), No. 11, pp. 889–894*).—The digestibility of silage made from Golden mung beans was determined at the Oklahoma Experiment Station with four milk cows receiving the silage alone over a period of 17 days.

The average composition of the fresh silage was 67.3 percent moisture, 4.8 percent crude protein, 7.3 percent crude fiber, 1.4 percent fat, 13.1 percent nitrogen-free extract, and 6.1 percent ash. The average coefficients of digestibility obtained were 45.2 for dry matter, 54.2 for protein, 47.8 for crude fiber, 72.6 for fat, and 57.8 for nitrogen-free extract. An attempt made to determine the digestibility by calculating the food substance to silica ratio of the feed failed because the silica content of the silage varied from day to day, presumably due to an uneven distribution of silica in the silage and to stratification and loss of silica in its passage through the intestinal tract.

Palatability of cottonseed and linseed meals, G. A. BRANAMAN (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 253, 254*).—A test with 12 heifer and 12 steer calves fed by the reversal method was undertaken to compare the palatability of 43-percent protein cottonseed meal and 37-percent protein linseed meal. All of the animals received the same basal ration fed twice daily in individual stalls.

No differences were noted in feed consumption to indicate a preference for either feed. The average daily gains and the amount of feed required per 100 lb. gain were also approximately the same whether the calves received cottonseed meal or linseed meal.

Analyses of feeds for farm animals (*U. S. Dept. Agr., Bur. Anim. Indus., [Anim. Husb. Div.], 1936, A. H. D. No. 20, pp. 6*).—Tables, compiled by G. L. Bidwell and A. T. Semple, give the chemical analyses and digestible nutrients of grains and their products; hays, stovers, and fodders; oil-bearing and legume seeds; green forages; roots, tubers, and fruits; silages; and miscellaneous byproducts.

Commercial feeding stuffs—report on inspection, 1935, E. M. BAILEY (*Connecticut [New Haven] Sta. Bul. 385 (1936), pp. 451–539+XVII–XX*).—This is the usual report of the guaranties and analyses of 1,320 samples of feeding stuffs collected for official examination during the calendar year 1935 (E. S. R., 73, p. 826).

Commercial feeding stuffs, H. R. KRAYBILL ET AL. (*Indiana Sta. Circ. 220 (1936), pp. 31, fig. 1*).—This is the condensed report of commercial feed inspection for 1935. A table lists the results of the examination of 2,827 samples of feeds and shows the number of samples incorrectly guaranteed, seriously deficient, or misbranded (E. S. R., 74, p. 81).

Analyses of commercial feeding stuffs and registrations for 1936, C. S. CATHCART (*New Jersey Stas. Bul. 608 (1936), pp. 64*).—Analyses are reported for protein, fat, and fiber of 1,579 samples of commercial feeding stuffs collected for official inspection during 1935, including a list of the ingredients found by microscopic examination (E. S. R., 74, p. 527).

Preserving farm-dressed meat in freezer storage, K. F. WARNER (*U. S. Dept. Agr., Bur. Anim. Indus., Anim. Husb. Div., 1935, A. H. D. No. 16, pp. 4*).—The development and uses of "freezer lockers" for preserving fresh meat are described, together with information on the preparation of the products for the lockers.

The estimation of the heat production of cattle from the insensible loss in body weight, H. H. MITCHELL and T. S. HAMILTON (*Jour. Agr. Res. [U. S.], 52 (1936), No. 11, pp. 837–854*).—Experiments were conducted at the Illinois Experiment Station to determine the insensible loss in body weight of steers under controlled conditions of environmental temperature and humidity and to correlate such losses with the heat production of the steers, determined in an open circuit respiration chamber.

The data showed that the percentage of insensible loss in body weight represented by vaporized water varied inversely with the respiratory quotient and approached 100 as the percentage of heat lost from the body by vaporization increased. The insensible loss was sensitive to changes in environmental temperatures, particularly above 70° F. Changes in relative humidity were without certain effect up to values of 80 percent or more. The hair coat, through its effect upon the vaporization of water from the skin, was a great factor in determining the insensible loss in body weight. Removal of most of the hair coat reduced the loss by 20 to 30 percent. A regular water intake favored a regular insensible loss in weight, while lack of water for several days depressed the insensible loss to abnormally low levels.

By rigorous control of all factors known to affect vaporization the day-to-day variation in the insensible loss of weight under the conditions of this study were reduced to a magnitude represented by a coefficient of variation of about 6 percent. The ratio between heat lost by vaporization and total heat output was not constant under the same environmental conditions but was an individual characteristic.

The success of a method of predicting the heat production of steers from their insensible losses in weight depended upon (1) a careful determination of the latter under standardized conditions, (2) a preliminary estimate on each animal of the fraction of heat lost in the vaporization of water under the given standardized conditions, and (3) fairly good estimates of the respiratory quotient to be expected from the experimental ration.

Color of lean of beef as affected by grass and grain feeding, J. H. LONGWELL (*West Virginia Sta. Bul. 274 (1936), pp. 8*).—Color readings were made with a spectrophotometer on beef samples taken from yearling, 2-year-old, and 3-year-old cattle fed either at Morgantown or Lewisburg. These animals had received varying amounts of grain and grass.

Analysis of the readings showed that grass as a feed did not produce dark lean in beef. The brightness of the lean appeared to be directly related to the degree of finish. While a few cattle in these tests killed dark, the individual animals came from different lots and the color was apparently without relation to the feed consumed. It is concluded that beef from grass-finished cattle can be as bright as beef from grain-finished cattle showing a comparable degree of finish.

Fertility in sheep: Artificial production of seminal ejaculation and the characters of the spermatozoa contained therein, R. M. C. GUNN (*Austral. Council Sci. and Indus. Res. Bul., 94, (1936), pp. 116, figs. 8*).—This bulletin presents a detailed description of a method of applying electrical stimulation to rams resulting in the emission of normal semen. Such stimulation caused a complete emptying of the vas deferens, the average ejaculation totaling about 1.5 ml. The effects of varying intensity of stimulation on certain body functions and the effects of a number of drugs on the reaction to stimulation are discussed.

Frequently induced ejaculation has proved harmless to rams. Spermatozoa obtained in this manner have survived 12 days or more when stored in vitro at 4° C. Other factors influencing the longevity of the spermatozoa stored in vitro are discussed. The results of trials in artificially inseminating ewes and the wider application of this method are discussed.

Raising export lambs on subterranean clover pasture lands, L. J. COOK (*Jour. Dept. Agr. So. Austral., 39 (1935), No. 1, pp. 36–44*).—This article presents data on the results of mating purebred Southdown, Dorset Horn, Suffolk, English Leicester, and Ryeland sires to thrifty comeback ewes (Merino rams × half-bred English Leicester-Merino ewes) with regard to efficiency of lambing, weight, carcass quality, market value of lambs, return of lamb value per ewe that bred, and returns per ewe less lamb grazing costs. Rather pronounced differences were noted in the net returns from lambs resulting from the different crosses.

In general it is concluded that the raising of fat lambs on improved pasture has been quite satisfactory, particularly when they were grazed on well fertilized pasture and when dropped sufficiently early to enable them to be marketed before grass approached maturity.

Sugar beet by-products for fattening lambs, A. S. INGRAHAM (*Wyoming Sta. Bul. 216 (1936), pp. 20, fig. 1*).—This series of lamb-feeding trials was designed to determine the value of sugar beet tops (pastured) as the only ration and when supplemented with either alfalfa or barley or both, and also the value of cured beet tops fed in dry lot and the comparative value of wet beet pulp and dried molasses pulp in the dry-lot ration.

Based on 3 years' trials beet tops fed by pasturing without any supplement were found to be a very satisfactory ration over a 6- to 8-week period and were shown to have a feed replacement value considerably greater than their ordinary selling price. The tops from 1 acre of beets yielding 18 6 tons provided ample feed for 1,000 lambs for 1 day. The addition of a small amount of alfalfa to the ration slightly increased the rate of gain, but did not add to the profits obtained. Adding barley to the ration either with or without hay materially increased the cost per pound of gain, although increasing the rate of gain and improving the finish on the lambs. The lambs receiving barley while on pasture made more rapid and more economical gains during the subsequent dry-lot feeding period.

Cured beet tops were found to be a satisfactory supplement to the dry lot ration, but the additional labor involved reduced net returns to approximately one-half those secured by pasturing the tops. Dried molasses pulp was less economical than wet pulp as a supplement to alfalfa and barley in the finishing ration.

The effect of feeds on the quality and palatability of lamb, J. E. RICHARDSON and W. F. DICKSON (*Montana Sta. Bul. 320 (1936), pp. 19*).—In this cooperative study, conducted between the departments of animal husbandry and home economics over a period of 9 years, it was found that the use of wheat screenings or dockage containing many hard weed seeds resulted in flabby meat covered with a scant layer of greasy fat and having a peculiar flavor. Of the various weed seeds fed the fanweed seed imparted the most objectionable flavor. When fed with alfalfa hay oats were slightly superior to wheat and barley in producing roasts of quality, juiciness, and general desirability. Barley appeared to produce consistently a rather greasy fat and a pronounced flavor in the lean. Adding wet beet bulp to a ration of wheat, barley, or oats and alfalfa hay improved the rate of gain and reduced the differences in palatability scores. Adding either dry or wet beet pulp to a ration of oats and alfalfa hay resulted in roasts that were similar and desirable in quality and palatability.

During the roasting process the total shrinkage averaged about 25 percent when roasts were cooked to 182° F. by an oven temperature of 257° after being seared 20 min. at 527°. Approximately one-half of the total shrinkage was by evaporation and the other half by drippings. These shrinkages were not appreciably altered by the ration fed or by the kind of cut roasted. It required about 40 min. per pound to roast loins to the well-done stage and about 37 min. per pound for leg roasts.

Winter forages for fattening hogs: A comparison of barley, rape, rye, and oats, E. D. KYZER, L. V. STARKEY, T. M. CLYBURN, and E. G. GODBEY (*South Carolina Sta. Circ. 54 (1936), pp. 12*).—In this study comparisons were made of dry-lot and pasture feeding, of winter forages for fattening pigs, and of protein supplements. In the phase of the work conducted at the Coast Substation white corn was fed, while at Clemson College yellow corn was used.

The results showed that when the basal ration consisted of white corn and menhaden fish meal the daily gains were significantly increased by the use of forages as compared with the gains in dry lot. With yellow corn forage did not produce significantly greater gains. In dry lot the white corn and fish meal ration sometimes produced a vitamin A deficiency that was apparently corrected by the use of green forage or yellow corn. Barley, rye, rape, and oats had approximately equal value when used as winter forages.

Forage reduced the concentrates needed per 100 lb. of gain about 5.4 percent when white corn was fed. In this case the amount of supplement was reduced 23 percent. With yellow corn the total feed per 100 lb. of gain was practi-

cally the same in dry lot and on forage, but forage reduced the need of supplement per unit of gain about 29 percent. The corn requirements per unit of gain were the same whether the protein supplement consisted of fish meal alone or of equal parts of fish meal and cottonseed meal The mixed supplement increased the amount of this nutrient required per 100 lb of gain 59 percent with white corn and 70 percent with yellow corn. The feed-saving value of an acre of forage was $9.65 when grazed by pigs fed white corn and $5.29 when yellow corn was used.

Grinding corn for swine, M. A. McCarty, J. E. Nicholas, and T. B. Keith (*Pennsylvania Sta. Bul. 326 (1936), pp. 11, figs. 3*).—A series of tests was conducted to determine the relative value of different degrees of fineness of grinding corn when compared with whole corn as measured by gain in body weight of growing and fattening pigs. The same basal ration was used for pigs fed individually in lots receiving fine-, medium-, and coarse-ground corn.

There was an advantage over whole corn of 17, 21, and 15 percent, respectively, in favor of fine-, medium-, and coarse-ground corn in total average daily gains for the pigs in these trials. These differences were not considered large enough to indicate that any one fineness of grinding was superior to that of any other.

The preparation of feed for colts, A. B. Caine (*Iowa Sta. Bul. 347 (1936), pp. 279–302, figs. 5*).—In order to determine the effects of rolled oats on the rate of gain, feed requirements, and cost of feeding draft colts, two experiments were conducted using 8 weanling colts in the first and 6 weanling and 4 yearling colts in the second test.

The results showed that colts made slightly larger gains and required less feed per unit of gain on prepared oats than on whole oats. The rolled oats were not so palatable as the whole grain. At the end of each experiment the colts fed rolled oats had the appearance of being fatter.

In a test to determine the value of preparation of roughage for colts it was found that the palatability of good quality roughage was not increased by grinding or cutting. Observations indicated that the advantage of chopping hay was due to the reduction in waste. Colts required more time to consume chopped hay than long hay.

[Poultry investigations in Rhode Island] (*Rhode Island Sta. Rpt. [1935], pp. 31, 32*).—Results obtained in a study of the effect of certain calcium intake levels on hatchability and eggshell formation are reported.

The secretory activity of the parts of the hen's oviduct, V. S. Asmundson and B. R. Burmester (*Jour. Expt. Zool., 72 (1936), No. 2, pp. 225–246, figs. 2*).—In an experiment at the California Experiment Station the effect of surgically resecting different sections of the oviduct on the shape, size, and composition of eggs was determined. In all cases the weight of the yolk was greater after the operation, while shape and size of the egg showed considerable variation. Removal of the anterior section of the albumin tube decreased the amount of liquid albumin, while removal of the posterior portion resulted in a decrease of the firm albumin and increase in the liquid fraction, indicating a qualitative difference in the secretion of the different sections of the albumin tube. Resection of part of the isthmus reduced the amount of shell membrane, while resection of the anterior part of the uterus reduced the amount of the shell. Only when the resected portion included more than one part of the oviduct was there a reduction in more than one part of the egg.

Seasonal changes in interior egg quality of Single Comb White Leghorn hens, J. A. Hunter, A. Van Wagenen, and G. O. Hall (*Poultry Sci., 15 (1936), No. 2, pp. 115–118, fig. 1*).—The [New York] Cornell Experiment Station has determined the seasonal change occurring in the interior quality of eggs over

a 1-yr. period, as indicated by the condition of firm albumin, the percentage of thin albumin, yolk index, and yolk color. Eggs of highest quality were produced from November to March, with a lowering of quality beginning in March and April and continuing through the summer. No seasonal change in yolk color was noted.

Salt requirements of poultry, J. G. HALPIN, C. E. HOLMES, and E. B. HART (*Poultry Sci., 15 (1936), No. 2, pp. 99–103*).—This study at the Wisconsin Experiment Station undertook to find the optimum level of salt supplement for poultry rations. Salt was added to the ration of day-old chicks in one trial at the rate of 0, 1, and 5 percent, and in a second trial at the rate of 0, 0.5, 1, and 2 percent of the basal ration. Feeding 5 percent of salt resulted in slower growth and a much higher mortality of chicks, particularly at 5 to 8 weeks. This lot also matured more slowly, came into production later, and laid fewer eggs. Comparatively little difference was noted in growth rates, mortality, or egg production of any of the other groups. Apparently 5 percent of salt is more than is desirable, 2 percent is neither injurious nor advantageous, while some salt seems desirable.

The distribution and storage of fluorine in the tissues of the laying hen, K. HAMAN, P. H. PHILLIPS, and J. G. HALPIN (*Poultry Sci., 15 (1936), No. 2, pp. 154–157*).—The Wisconsin Experiment Station has studied the effect of adding fluorine-bearing minerals (raw rock phosphate and phosphatic limestone) to the basal diet of laying hens on the fluorine storage in various body tissues. With the fluorine content of the ration ranging from 0.005 to 0.105 percent, the storage was found to be directly proportional to the level fed. Most of the fluorine was contained in the bones, with small quantities in the active tissues such as the liver and kidneys, still less in muscle tissue, and very little in the fat.

Artificial insemination of fowls (*U. S. Dept. Agr., Bur. Anim. Indus., Anim. Husb. Div., 1936, A. H. D. No. 19, pp. 2*).—A method of obtaining spermatozoa from male birds and the technic of artificial insemination of hens are described.

The effect of cod-liver oil in the diet of the mother hen on embryo mortality and on the calcium and phosphorus content of the embryo, W. M. INSKO, JR., and M. LYONS (*Kentucky Sta. Bul. 363 (1936), pp. 63–81, figs. 3*).—The data reported in this bulletin were concerned with embryo mortality as influenced by cod-liver oil fed to White Leghorn pullets (1) confined to the house with sunshine only through window glass, (2) confined to the house and allowed sunshine in a wire-screened porch, and (3) allowed bluegrass range. A study was also made of the effect of the first and third sets of conditions upon the calcium and phosphorus content of the embryo.

Pullets confined without vitamin D supplement produced eggs having a very high embryo mortality during the third week of incubation. Exposure to sunshine or access to bluegrass range markedly reduced mortality during this period, and the range was more effective than sunshine alone. Adding cod-liver oil to the ration under the above conditions decreased embryo mortality during the third week. The decrease was most marked in the confined lot, with only a slight decrease in the bluegrass lot.

The calcium and phosphorus content of embryos from the pens receiving no antirachitic treatment was consistently less after the sixteenth day than that of embryos from other pens. The greatest difference in this respect occurred on the eighteenth or nineteenth day of incubation, which coincided with the peak of embryo mortality during the last week of incubation.

Studies on the calcium metabolism of laying hens, H. J. DEOBALD, E. J. LEASE, E. B. HART, and J. G. HALPIN (*Poultry Sci., 15 (1936), No. 2, pp. 179–185, figs. 3*).—The Wisconsin Experiment Station has studied the effect of various

levels of calcium intake on the blood calcium, skeletal calcium, and calcium content of the eggs produced, also the effect of parathormone injections during calcium starvation on the calcium metabolism.

The blood calcium of hens on low calcium intake was lowered, but for any individual hen the variation during her complete egg cycle (36 hr.) was not more than 4 mg per 100 g of whole blood. When hens were deprived of calcium the calcium content of eggshell was reduced to less than 25 percent of the normal, egg production virtually ceased within 12 days, and approximately 10 percent of the skeletal calcium was removed to supply the requirement for eggshell formation. During calcium starvation repeated 1-cc injections of parathormone had no noticeable effect on calcium metabolism, while single large injections produced marked rise of the blood calcium 3 to 7 hr. after injection in actively laying hens.

Effect of packing materials on the flavor of storage eggs, P. F. SHARP, G. F. STEWART, and J. C. HUTTAR ([*New York*] *Cornell Sta. Mem. 189 (1936), pp. 26, figs. 6*).—For this study clamp-top glass fruit jars were packed with two layers of four eggs each, together with half a filler, or one flat, or a corresponding amount of other material being investigated. Clean, unwashed eggs from 2 to 4 hr. old were used. The eggs were sealed in the jars, with provisions for reducing the humidity due to the continuous escape of moisture from the eggs. The jars were placed in storage at 30° to 34° F. After being removed from storage, the eggs were immersed in boiling water for 2.75 min., the blunt end of the shell removed, and the yolk mixed with the uncoagulated part of the white. The eggs were then tasted by selected judges.

The mean of a number of taste scores gave a reliable quantitative value for the flavor of eggs and could be used as a measure of the effect of factors involved in their production. The linear relation found between odor and taste of eggs indicated that the flavor obtained by tasting was due largely to the sense of smell. Great variations were found among the different persons in the ability to score eggs for flavor. There were no indications that the judges became unreliable because of fatigue after scoring from 4 to 10 eggs. The maximum ability to judge for flavor was attained only after a number of eggs had been tasted. The results did not substantiate the claim that for best flavor discrimination the eggs must be tasted while hot. Better agreement in score of eggs was obtained with good- and bad-flavored eggs than with eggs of intermediate flavor. One judge was unable to detect "musty" eggs.

The glass jars equipped with the humidity-regulating solutions proved very satisfactory for determining the effects of absorption of flavors from packing materials. These materials varied in transmitting flavors to eggs during storage. Eggs of relatively high pH developed a more undesirable flavor in storage, regardless of the type of packing, than did eggs in which the pH was held low. The effect of increasing humidity on absorption of flavors from the materials was determined by the properties of the packing material itself.

Levels of meat scraps and dried milk in rations for young ducks, R. E. ROBERTS (*Poultry Sci., 15 (1936), No. 2, pp. 136–140*).—The Indiana Experiment Station has studied the effectiveness of rations containing meat and bone scrap and dried skim milk in percentage ratios of 20:5, 15:5, 10:5, and 10:0 for growing young ducks. The ration containing 10 percent of meat and bone scrap and 5 percent of dried skim milk proved entirely satisfactory and was superior to the ration containing no dried milk. While slightly less feed was required per unit of gain on the higher protein rations, there seemed but slight justification for using more than 10 percent of meat scrap. No differences in mortality could be attributed to the different rations.

Force-molting of White Leghorn hens, F. L. Knowlton (*Oregon Sta. Circ. 119 (1936), pp. 8*).—A comparison of the records over a 2-yr. period of force-molted and naturally molted flocks showed that forced molting was not profitable and could not be recommended as a dependable method of increasing the income. Mortality was about twice as high in the force-molted flock that was subsequently kept under all-night lights as in the naturally molted flock. Severe culling was necessary to keep production above 50 percent in the force-molted flock, while none was needed in the naturally molted flock. Egg production was also higher in the naturally molted flock.

Carbon monoxide poisoning in chickens, G. W. Stiles, Jr. (*Poultry Sci., 15 (1936), No. 3, pp. 270–272, fig. 1*).—This paper describes two cases in which death of hens was definitely diagnosed as due to carbon monoxide poisoning, evidently due to a smoky kerosene lamp used for tempering drinking water. It is suggested that smoky kerosene lamps in brooder houses may be the source of previously unexplained losses in chicks and turkey poults.

Effect of season on the growth and feed consumption of turkeys, V. S. Asmundson and W. E. Lloyd (*Poultry Sci., 15 (1936), No. 2, pp. 186–191, fig. 1*).—This study from the California Experiment Station indicates that early-hatched turkey poults grew more rapidly than late-hatched birds during the first 8 to 12 weeks, after which the latter group gained more rapidly, until at 32 weeks there was no significant difference in the size of the females of the two groups. However, the early-hatched males were still heavier than the later-hatched group. Prevailing temperatures while birds were actively growing seemed the most probable explanation of these differences in growth rate. The amount of feed consumed varied directly with the amount of gain, at least to 16 to 20 weeks, while the feed required per unit of gain increased with age in all cases.

Studies relative to the estimation of vitamin D, II, III (*Poultry Sci., 13 (1934), No. 6, pp. 353–357, figs. 2; 15 (1936), No. 2, pp. 127–135, figs. 2*).—This series of studies (E. S. R., 73, p. 832) has been continued.

II. *Effect of seasonal variation and sex upon calcification in rachitic chicks,* L. L. Lachat.—Groups of day-old chicks, including both sexes, were fed rachitogenic diets for either 4- or 5-week periods. Bone ash analysis showed chicks of both sexes to be markedly rachitic at 4 weeks as well as 5 weeks of age. No significant difference was noted in the bone ash content of males and females. A seasonal difference in the rate of calcification was noted, which could be divided into definite seasonal periods.

III. *Effect of calcification upon growth and sex differences in White Leghorn chicks,* L. L. Lachat and H. A. Halvorson.—In this series of tests six groups of day-old chicks, including both sexes, were fed on the basal rachitogenic diets plus varying quantities of antirachitic supplements at such levels as to produce a range from severe rickets and subnormal growth to normal calcification and growth during the 4-week period. Apparently deprivation of vitamin D affects growth and calcification of females more seriously than males, although females utilized vitamin D more efficiently. A high degree of correlation was found to exist between body weight and calcification, amounting to 0.759 ± 0.02 for males and 0.819 ± 0.014 for females. Since growth rates are seasonally affected, this relationship explains the seasonal variations in calcification as noted above. Females are considered more satisfactory than males for vitamin D investigation.

Comparison of digestibility in gizzardectomized and normal fowls, J. C. Fritz, W. H. Burrows, and H. W. Titus (*Poultry Sci., 15 (1936), No. 3, pp. 239–243*).—In this study at the U. S. D. A. Beltsville Research Center three birds from which the gizzards had been surgically removed and four normal birds

were used in a series of digestion trials in which coefficients of apparent digestibility were determined for ground yellow corn, coarsely cracked yellow corn, and cracked soybeans. The rate of food passage through the digestive tract of the gizzardectomized birds was more rapid, particles of corn appearing in the droppings within 95 min, after ingestion. This group showed a much lower digestibility of all constituents than the normal birds when coarse feeds were given. When ground corn was fed there was a small but consistent difference in favor of the normal lot, with the greatest difference observed in the digestibility of the crude protein.

The differences were not sufficiently great to indicate a secretion of digestive enzymes in the gizzard, and apparently it functions largely, if not solely, as a grinding organ.

Influence of egg production and other factors on the iron content of chicken blood, A. R. WINTER (*Poultry Sci., 15 (1936), No. 3, pp. 252–255*).—The Ohio State University made iron determinations on the blood of approximately 300 hens from 14 to 16 mo. of age. This included hens in production, both on range and under confinement, and some with complications such as gray eyes and bumblefoot, and on hens out of production, some of which were in molt.

Rather wide variations in the iron content of the blood were noted, ranging from 20.1 to 37.2 mg per 100 cc of blood, with an average of 27.1±0.2 mg. Approximately the same range was found in each of the groups studied, leading to the conclusion that production, confinement, molt, gray eyes, or bumblefoot do not produce quickly noticeable or marked changes in the iron content of the blood.

A preliminary report on the injurious effect of sodium bicarbonate in chicks, J. F. WITTER (*Poultry Sci., 15 (1936), No. 3, pp. 256–259*).—In this study from the University of Maine the effect of adding various concentrations of sodium bicarbonate to the drinking water of young chicks was determined.

A 0.6-percent solution caused an increase in water consumption and moist droppings but apparently had no injurious effects on chicks over 2 weeks old, although swollen kidneys were observed in younger chicks. A 1.2- or 2.4-percent solution seriously affected young chicks, caused enlargement and serious damage to the kidneys, increased the uric acid content of the body, reduced vitality, and caused mortality. Sodium bicarbonate apparently is not an entirely safe drug for poultrymen to use, and dosage should be carefully gaged to meet the age tolerance of the chicks.

Inorganic phosphorus and perosis, J. C. HAMMOND (*Poultry Sci., 15 (1936), No. 3, pp. 260–263*).—This paper from the U. S. D. A. Beltsville Research Center presents correlations made on 191 lots of Rhode Island Red chickens, of which 58 lots received rice bran in their diet.

Perosis was found to be highly correlated with inorganic phosphorus, less correlated with total phosphorus, and negatively correlated with organic phosphorus. Rice bran had a marked effect on the correlation of perosis to both inorganic phosphorus and calcium, indicating that there is a factor in rice bran which assists in the regulation of calcium and phosphorus metabolism. It appears that inorganic phosphorus is a primary factor in the etiology of perosis.

The influence of single grains on slipped tendons, H. L. WILCKE (*Poultry Sci., 15 (1936), No, 3, pp. 264–269, figs. 2*).—The Iowa Experiment Station has studied the effect of adding a single kind of grain and various combinations to a satisfactory basal ration on growth rates and frequency of slipped tendon in chicks.

A ration of ground oats plus the basal mixture gave the highest growth rate and freedom from any abnormalities. Ground wheat plus the basal mixture did not support normal growth, apparently due to vitamin A deficiency. Chicks fed

a ration of ground yellow corn plus the basal mixture made slow growth, though very few slipped tendons were noted. Supplementing the ration with either corn bran, yeast, or 10 percent of ground oats did not prevent slipped tendons, but the addition of 20 percent of ground oats or either 10 or 20 percent of rice bran exerted a beneficial effect in this respect. Failure of the corn bran or yeast to give protection indicates that the beneficial effect of oats or rice bran cannot be explained on the basis of either increased fiber content or increase in the vitamin B complex of the ration.

Numbers and uniformity in experimental lots, F. A. HAYS (*Poultry Sci., 15 (1936), No. 3, pp. 235–238. figs. 5*).—This paper from the Massachusetts Experiment Station discusses essential points to be considered in the selection of experimental lots when annual egg production is to be used as a measure of experimental results.

Curves are presented to show the frequency distribution observed in certain groups with reference to annual egg production, age at which first egg was produced, and differences between first and second year's egg production. It is recommended that 100 birds may be a fair sample in an improved flock, while greater numbers are necessary for mixed or unimproved stock. Yearling hens were somewhat less variable in egg production than pullets.

Five years' management tests with chicks and pullets, D. C. KENNARD and V. D. CHAMBERLIN (*Poultry Sci., 15 (1936), No. 3, pp. 230–234*).—From studies at the Ohio Experiment Station data are presented on the egg production and the degree of mortality of groups of pullets confined, allowed access to fresh range, and access to old or used range. No significant difference in mortality was noted among these groups, while pullets on fresh range produced more eggs. Tests were also conducted in which healthy layer pullets were imported from healthy flocks and compared with similar strains in the station flock, both when kept in separate lots and when mixed with the station pullets. In every case mortality was less and egg production was greater for the imported pullets than for those raised at the station. Suggestions are made regarding the shortcomings of sanitary measures as a means of controlling such diseases as paralysis, leucosis, typhoid, and cholera-like diseases, and the possibility of eliminating infection by removing all infected and carrier individuals from the premises periodically and making a fresh start.

The selection and management of turkey breeders, D. R. MARBLE and P. H. MARGOLF (*Poultry Sci., 15 (1936), No. 3, pp. 225–229*).—In a 3-yr. study at the Pennsylvania Experiment Station, eggs produced by turkeys on limited range gave better hatchability than those from turkeys in confinement, though total egg production was not greatly influenced. Both fertility and hatchability greatly decreased with advance of season from March until July. Medium-sized eggs (from 84 to 89 g) gave a higher percentage hatch than either extremely large or small eggs. Pullets produced more eggs than yearling hens, with no particular difference noted in either fertility or hatchability of the two lots.

The relationship of protein supplement to interior egg quality, D. F. SOWELL and C. L. MORGAN (*Poultry Sci., 15 (1936), No. 3, pp. 219–222*).—This study at the South Carolina Experiment Station involved the use of four different mash rations each fed to duplicate groups of pullets under ordinary housing conditions and confined in individual laying cages. The housed pullets received a grain mixture in addition, while the caged birds received only the mash ration. Monthly egg samples (three consecutively laid eggs) were taken for study, which included weight, width, and height of yolk, color of yolk, and weight of the thick white. It appeared that the source of protein supplement fed had no material effect on the interior physical quality of the eggs produced.

Further studies on the effect of sources of vitamin D in the diet of the chicken on storage of the antirachitic factor, G. M. DE VANEY, H. E. MUNSELL, and H. W. TITUS (*Poultry Sci., 15 (1936), No. 2, pp. 149–153*).—Continuing this investigation (E. S. R., 70, p. 372), a study was made of the effect of adding varying quantities of vitamin D from either cod-liver oil or viosterol, but mixed with corn oil in such proportion that 8 percent of fat was added to the diet in each case. This level of fat in the diet apparently exerted no inhibiting effect on vitamin D storage, which amounted to about 2 percent of the amount ingested when 2 and 4 percent of cod-liver oil or 8 percent of viosterol 5D was fed. The percentage retention was somewhat lower when 8 percent of cod-liver oil or 2 or 4 percent of viosterol 5D was fed. The number of eggs per bird was quite similar in all trials except in the case of those receiving 8 percent of cod-liver oil, where egg production was markedly decreased.

Poultry culture in the Salt River Valley of Arizona, B. W. HEYWANG (*U. S. Dept. Agr., Bur. Anim. Indus., Anim. Husb. Div., 1935, A. H. D. No. 15, pp. 3*).—Poultry production in Arizona, including problems in feeding, housing, diseases, and marketing of products, is discussed.

Poultry specialty clubs (*U. S. Dept. Agr., Bur. Anim. Indus., Anim. Husb. Div., 1936, A. H. D. No. 18, pp. 2*).—The names of poultry specialty clubs, together with the name and address of the secretary of each club, are listed.

Some causes and effects of a high free fatty acid content of the meat-scraps in poultry rations, C. H. SCHROEDER, G. K. REDDING, and L. J. HUBER (*Poultry Sci., 15 (1936), No. 2, pp. 104–114, figs. 3*).—This contribution describes a series of chick feeding tests to determine the effect of rations containing meat scraps of high or low free fatty acid content, both before and after extraction of the fat and with and without vitamin A and D supplements.

In every instance feeding meat scraps of high free fatty acid content gave inferior results to those secured from low free fatty acid rations. Extracting the fat did not materially improve the results from the former, while adding this extracted fat to the latter rations did not decrease their efficiency. This addition of vitamin A and D supplements, particularly the former, greatly improved results from the high free fatty acid ration, indicating that inactivation of these vitamins resulted when a high percentage of free fatty acid is present. The effect of storage conditions on the rate of development of free fatty acid is discussed.

Shell characteristics and their relationship to the breaking strength, G. F. STEWART (*Poultry Sci., 15 (1936), No. 2, pp. 119–124, figs. 2*).—This study from Cornell University describes certain new measurements considered desirable in determining egg shape. It was found that there was very little relation between shape of eggs and their breaking strength, while a correlation of 0.509 ± 0.028 was found between shell thickness and breaking strength.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products in Indiana] (*Indiana Sta. Rpt. 1935, pp. 27–33, 53, 57, 58*).—Results are noted on the value of legume hay and cracked corn as a ration for growing dairy calves and as a winter ration for yearling dairy heifers, the value of alfalfa hay and ground shelled corn as a ration for dairy cows, the fat test of milk as affected by soybean products, factors in soybeans responsible for the suppressing action in vitamin A formation in butter, the effect of feeds upon the vitamin A content of butter with special reference to the rapidity of change in the vitamin A activity of such butter, and the vitamin A potency of carotene fed in butterfat and Wesson oil.

Investigations with dairy products yielded information on the vitamin A activity of butter produced by cows fed alfalfa hay and soybean hay cut in different stages of maturity; the relationship between carotene, color, and vitamin A in butter; the enzymes in sweet and sour farm-skimmed cream as related to keeping quality of the butter; the effect of H-ion concentration and season of the year upon the keeping quality of butter as manufactured under commercial conditions; physical, chemical, and bacteriological factors affecting the body, texture, and quality of ice cream; the character of Indiana butter from the standpoint of quality; the cause and remedies of some abnormal flavors in milk with special reference to cappy flavor; the methods used in washing and sterilizing milking machines; grading cream for butter making; milk quality improvement; and the change in vitamin A activity of butter following a change in the vitamin A intake of cows.

Growth and development with special reference to domestic animals, XXXVIII, XXXIX, S. BRODY and R. CUNNINGHAM (*Missouri Sta. Res. Buls. 238 (1936), pp. 52, figs. 5; 239 (1936), pp. 47, figs. 17*).—This is a continuation of this series of studies (E. S. R., 74, p. 828).

XXXVIII. *Further studies on the energetic efficiency of milk production and the influence of live weight thereon.*—Continuing the line of investigation as noted (E. S. R., 73, p. 663), data on milk production, feed consumption, live weights, and weight gains were analyzed on four groups of high-producing cows, totaling 368 individuals. The results of these analyses showed a range of energetic efficiency for milk production for the different groups from 28 to 34.4 percent (the previous report indicated this to be of the order of 30 percent for good cows), with evidence that this factor is practically independent of live weight. Two champion milk producers, a Holstein weighing 1,700 lb. and a Jersey weighing 700 lb., were shown to have very high energetic efficiency, amounting to 43.5 and 47.5 percent, respectively, the latter figure probably nearing the limit of biological possibility. The applicability of the law of diminishing returns to the gross and net costs of milk production is fully discussed, and curves are presented to indicate that successive efficiency increments decline exponentially with successive milk increments in their approach to a theoretical maximum efficiency of about 60 percent. A marked similarity is noted for the energetic efficiency of milk production for "good" cows, regardless of live weight and the gross efficiency of early postnatal growth on "good" diets for different species of animals regardless of size, namely, about 30 percent.

XXXIX. *Relation between monetary profit and energetic efficiency of milk production with special reference to the influence of live weight thereon.*—This phase of the investigation is introduced by pointing out that energetic efficiency of milk production is the ratio of the energy output as milk to the energy expended as digestible feed, whereas monetary profit of milk production is the difference between money realized for milk produced and money expended for the feed consumed, and the fact is emphasized that these two factors cannot be considered as identical. The question is raised as to whether profits should be computed on the basis of a cow, a unit of live weight, a unit of milk produced, or a unit of feed consumed, and what influence live weight has on each of these varieties of profit.

Based on analyses of extensive data, it is concluded that profit per cow increases with increasing size of cow. Profit per unit of live weight decreases with increasing size, while profit per unit of milk produced and per unit of feed consumed tends to be independent of the size of the animal and almost directly proportional to gross energetic efficiency of milk production, which factor is considered the only logical measure of physiological dairy value. Nomographs are presented for estimating gross energetic efficiency for various levels of live

weight and milk production and for estimating the several kinds of profit described based on given prices for milk and feed.

Influence of preceding dry period and of mineral supplement on lactation, P. T. D. ARNOLD and R. B. BECKER (*Jour. Dairy Sci., 19 (1936), No. 4, pp. 257–266, figs. 3*).—An analysis of milk production records at the Florida Experiment Station indicated that a dry period of from 31 to 60 days allowed maximum milk yield in Jersey cows, while a dry period of less than 30 days resulted in an early decline. A dry period of over 91 days appeared to result in lower milk production. Analysis of records made before and after bonemeal was fed at the rate of 2 percent of the grain ration indicated that a 45-percent increase in milk production resulted from the bonemeal feeding, with significantly greater persistence noted in the bonemeal group.

The influence of rations low in certain minerals on the composition of the blood and milk of cows and on the blood of their progeny, J. W. GROENEWALD (*Onderstepoort Jour. Vet. Sci. and Anim. Indus., 4 (1935), No. 1, pp. 93–165, figs. 16*).—This study involved the use of 12 yearling Friesland heifers and extended over a 30-mo. period. All animals received the same low mineral basal ration, with various mineral supplements allowed so that the ration of each pair, except the control animals, was deficient in at least one essential mineral. Extensive tables and curves present the mineral content of the blood and milk of the cows and of the blood of their offspring from birth to 85 days of age.

Mineral-deficient rations were not reflected in abnormal blood analysis except in the case of low phosphorus intake, which caused a subsequent lowering of inorganic blood phosphorus, ultimately causing death of the animal.

The composition of the milk was definitely not influenced by the character of the ration. Significant changes were noted to occur in the mineral content of the blood of calves from 1 to 3 mo. of age.

The effect of intravenous injections of sugar upon the lactating bovine, W. R. BROWN, W. E. PETERSEN, and R. A. GORTNER (*Jour. Dairy Sci., 19 (1936), No. 3, pp. 177–184, figs. 2*).—The Minnesota Experiment Station has studied the effect of injecting varying quantities of isotonic solutions of different sugars into the blood stream of lactating cows on the blood sugar content and on the lactose content of milk. Glucose injection tended to cause a slight hypoglucemia, followed by a marked hyperglucemia and a later drop to subnormal levels. Fructose injections caused a more pronounced hypoglucemia, while only lactose injections caused a pronounced hyperglucemia of considerable duration. Any increases in lactose secretion following these injections were so slight and so variable as to be of little significance, indicating that this procedure is of doubtful value in a study of lactose synthesis.

Intra-mammary duct injections in the study of lactose formation, W. R. BROWN, W. E. PETERSEN, and R. A. GORTNER (*Jour. Dairy Sci., 19 (1936), No. 4, pp. 243–256, figs. 11*).—The object of these experiments at the Minnesota Experiment Station was to produce a hyperglucemic condition in milking cows and, succeeding in this, to determine its effect on lactose secretion.

Eleven tests are reported in which varying concentrations of different sugar solutions were injected into the right half of the mammary gland of cows immediately following a normal milking period and in amounts practically equal to the amount of milk removed. It is concluded that such intramammary duct injections will produce a hyperglucemia providing that sufficient sugar is injected. Since increased insulin activity is stimulated by the inflow of sugar into the blood, injection of smaller quantities of sugar actually resulted in hypoglucemia.

Marked tremors were produced in the majority of the cases, closely followed by a marked rise in the blood sugar and increased body temperature, and accompanied by pronounced diuresis. The hyperglucemic condition resulted in only slightly increased lactose secretion, indicating that the optimum level of lactose secretion is very close to the maximum.

A note on the comparative economic efficiency of the Indian cow, the half-bred cow, and the buffalo as producers of milk and butter fat, K. P. R. KARTHA (*Agr. and Livestock in India, 4 (1934), No. 6, pp. 605–623, fig. 1*).—This contribution presents extensive data on the average milk and butterfat production of various strains of native Indian cattle, half-bred cows, and buffalos, with statistical constants for the distribution of milk yield among the various classes. Data are also presented on the comparative frequency of abortion among the various classes.

Studies on economy of milk production show that the buffalo, although not possessing the latent milking qualities of either the native Indian cow or the half-bred cow, is well adapted for the native villager where cheap grazing is available. Under conditions of high roughage cost the half-bred cow excels either the native cow or the buffalo.

The effect of early breeding upon the milk energy production of grade and purebred Toggenburg goats, O. C. CUNNINGHAM and L. H. ADDINGTON (*Jour. Dairy Sci., 19 (1936), No. 6, pp. 405–409; abs. in New Mexico Sta. Press Bul. 792 (1936), p. 1*).—Data are presented to show that a group of milk goats which first freshened at from 11 to 14 mo. of age and were milked only from 5 to 7 mo. during the first lactation produced slightly more milk as 2-year-olds (second lactation) than a similar group which freshened for the first time at about 2 yr. of age.

The results indicate that it is feasible to hasten the increase of the number of generations of female goats and the size of the herd by breeding the does to freshen for the first time at from 11 to 14 mo. of age.

Observations on the occurrence of supernumerary teats in dairy cattle, T. T. DAVID (*Philippine Jour. Anim. Indus., 2 (1935), No. 5, pp. 319–325, pls. 2, fig. 1*).—This article from the University of the Philippines notes that of 104 cows examined 23.07 percent had supernumerary teats. The caudal type was most commonly observed, being present in 66.6 percent of the individuals having extra teats. In all, 11 different patterns of extra teats were observed.

Simple versus complex ration for winter feeding of dairy cows, R. E. HORWOOD and J. G. WELLS, JR. (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 248–253*).—In order to compare a simple and a complex ration for dairy cows two trials were conducted with two groups of four cows each, using the double reversal system of feeding. In the first trial a ration of mixed hay and ground corn was compared with a ration of mixed hay, sunflower silage, roots, and a grain mixture. In the second trial the simple mixture consisted of alfalfa hay and ground barley and the complex ration of alfalfa hay, roots, and a grain mixture.

In the first trial the cows on the complex ration produced 5.6 percent more 4-percent fat-corrected milk than when on the simple ration. On the complex ration the animals lost 206 lb. but gained 389 lb. in weight on the simple ration. During the second trial the complex ration increased the yield of 4-percent fat-corrected milk 12 percent. However, the simple ration put 335 lb. of gain on the cows, while they gained only 56 lb. on the complex ration. During both trials the cows consumed 414.5 lb. more digestible protein and 298.5 lb. less total digestible nutrients while receiving the complex ration.

97008—36——7

Legume hay with and without high protein concentrates for dairy cows, J. H. HILTON, J. W. WILBUR, and W. F. EPPLE (*Indiana Sta. Bul. 407 (1936), pp. 4, fig. 1*).—Using the double reversal method of feeding four trials, divided into three 30-day experimental periods each, were conducted. Soybean hay was fed in the first two trials and alfalfa hay in the last two. The hay was the only source of roughage and was fed at the rate of 2 lb. per 100 lb. of live weight. In addition one group of cows in each test received a grain mixture of 400 lb. of ground corn and 200 lb. of ground oats, while the second group had the same mixture plus 50 lb. of linseed oil meal. The grain was fed at the rate of 1 lb. for each 3 lb. of milk produced.

There was no significant difference in the milk and butterfat production, feed consumption, or body condition between the groups of cows. It was shown that good average milk production could be maintained by liberal feeding of good quality of legume hay supplemented by a grain mixture of corn and oats. For high-producing cows or when the hay was of inferior quality it was suggested that some protein supplement may be needed. No minerals were fed in these trials, but it was thought that it might be wise to add 2 lb. of steamed bonemeal to each 100 lb. of the corn and oats mixture or to substitute wheat bran for part of the oats in order to keep up the phosphorus content of the ration.

The digestibility and feeding value of Russian thistle hay, H. W. CAVE, W. H. RIDDELL, and J. S. HUGHES (*Jour. Dairy Sci., 19 (1936), No. 4, pp. 285–290*).—The results of this study at the Kansas Experiment Station show that Russian-thistle hay is high in protein and ash but relatively low in total digestible nutrients as compared with other nonlegume roughages.

In a feeding trial it was demonstrated that the thistle hay was inferior to alfalfa, supplying 44.1 percent of the total digestible nutrients in the ration as compared with 56.3 percent supplied by alfalfa. The thistle hay was much less palatable, and furthermore it had to be ground because of the coarse spiny nature of the plant. No appreciable off flavors or odors developed in the milk produced.

Calcium and phosphorus requirements of dairy cows.—III, Relative values of dicalcium phosphate and bone meal as mineral supplements, J. A. NEWLANDER, H. B. ELLENBERGER, and C. H. JONES (*Vermont Sta. Bul. 406 (1936), pp. 16*).—Continuing this study (E. S. R., 68, p. 370), two cows have been kept continuously on mineral balance trials over two complete lactation periods. Each cow received Dicapho, a commercial dicalcium phosphate, during the first lactation period and steamed bonemeal during the second period, one animal receiving the supplements continuously while the other one was alternated for periods of from 6 or 9 weeks with and without them.

Making allowance for differences in the rate of mineral intake and the total quantities of milk produced, these two supplements, when fed at the rate of 100 g daily per cow, proved to be practically equal in calcium and phosphorus assimilability.

The effect of type of feed on the solids-not-fat content of milk, L. L. ROUX, G. N. MURRAY, and D. J. SCHUTTE (*Onderstepoort Jour. Vet. Sci. and Anim. Indus., 4 (1935), No. 1, pp. 167–197, figs. 2*).—In this investigation three groups of six cows each were fed a heavy concentrate ration, a heavy dry roughage ration, and a heavy succulent ration, respectively. Extensive tables are presented to show the feed consumption, live weight, milk production, butterfat and solids-not-fat content of milk, and a statistical analysis of these data.

The heavy concentrate ration maintained a higher level of production, a normal trend for solids-not-fat, and a slow increase in percentage of butterfat with advance in lactation. The other rations, both giving similar results, ap-

peared to have a depressing effect on the percentage of solids-not-fat, and milk production dropped more rapidly and the percentage of butterfat increased to a greater extent than occurred in the heavy concentrate group.

Taint in milk during the feeding of molassed beet pulp, H. T. CRANFIELD and J. MACKINTOSH (*Jour. Min. Agr. [Gt. Brit.], 42 (1935), No. 6, pp. 551–560*).—In a series of feeding experiments in which several lots of molasses beet pulp were fed to milking cows it was demonstrated that certain lots gave rise to a taint in milk flavor ranging from a mild off flavor to a decidedly fishy flavor. This condition occurred in only a few lots but apparently was most likely to come from dark-colored pulp. It is suggested that certain nitrogenous compounds occurring in beet pulp, capable of being broken down to produce trimethylamine, are the cause of this fishy taint.

Raising dairy calves, L. L. ROUX (*Onderstepoort Jour. Vet. Sci. and Anim. Indus., 4 (1935), No. 2, pp. 495–539, figs. 42*).—This is a report of a comparative feeding test in which a group of Friesland calves reared to 6 mo. of age on a limited quantity of whole milk, a specially compounded calf meal mixture, and alfalfa hay was compared with a similar group of calves receiving whole milk, skim milk, a simple grain mixture, and hay. These two groups respectively consumed 527 and 333 lb. of whole milk, 0 and 1,738 lb. of skim milk, 388 and 364 lb. of dry concentrate mixture, and 529 and 529 lb. of hay, and at 6 mo. of age were 85- and 113.2-percent normal in weight and 99.1- and 99.9-percent normal in height. Both groups made satisfactory growth on pasture after 6 mo. of age. While the milk substitute ration did not prove as efficient as the skim milk ration, both are considered suitable and economical.

Factors affecting the composition of milk, C. W. TURNER (*Missouri Sta. Bul. 365 (1936), pp. 30, figs. 10*).—In this bulletin the author has compiled the existing information on the composition of the milk of various animals, variations between breeds and individuals, the relation between fat and other constituents of milk, and the nutritional, physiological, and managerial factors affecting the composition of milk.

Butterfat and total solids in New England farmers' milk as delivered to processing plants, M. S. JACOBSON (*Jour. Dairy Sci., 19 (1936), No. 3, pp. 171–176, figs. 3*).—The author has examined over 100,000 samples of milk delivered to New England milk plants. He shows that for each 0.1-percent increase in butterfat there is a corresponding increase of 0.04 percent in solids-not-fat, with only slight seasonal variations in this relationship.

It is pointed out that milk meeting the Massachusetts minimum legal requirement for butterfat (3.35 percent) was below the standard (12 percent) for total solids. The desirability of two legal standards, one to cover milk sold by the producer to the dealer and the other to cover milk sold to the consumer, are discussed.

Normal variations in the curd tension of milk, W. H. RIDDELL, W. J. CAULFIELD, and C. H. WHITNAH (*Jour. Dairy Sci., 19 (1936), No. 3, pp. 157–164*).—The Kansas Experiment Station has investigated the effect of a number of factors on the curd tension of milk as measured by a modification of the Hill test. Considerable daily variation in the test of individual cows was noted, with coefficients of variation over a 10-day period ranging from 23.5 for a cow averaging 19.1 g to 7.5 for a cow averaging 83.5 g.

Colostrum was found to have a relatively high curd tension, reaching an average maximum on the third day after parturition. A rapid decline in firmness of curd was noted from the third to the tenth day, with a gradual decline beyond this point until the lowest curd tension was reached during the second and third months of lactation, followed by a gradual rise to the end of the

lactation period. Breed was found to be an important factor, and in order of softness of curd ranked Holstein, Ayrshire, Guernsey, and Jersey in this study.

A study of the titratable acidity of milk, I, II, W. J. WILEY (*Jour. Dairy Res. [London], 6 (1935), No. 1, pp. 72–85, figs. 10; 86–90, figs. 3*).—Two studies are reported from the Government Chemical Laboratory, Brisbane.

I. *The influence of the various milk buffers on the titration curves of fresh and sour milk.*—Simple solutions containing the various buffers naturally occurring in milk were studied as a means of determining the effect of each on the milk titration curve, when titrated to the phenolphthalein end point with sodium hydroxide. Titrations were made within definite pH ranges, using pH 4.8 to 8 as simulating sour milk and 6.6 to 8 as typical of fresh milk. Curves are presented to show the order of magnitude of the changes in the titration caused by each of the main buffer constituents. Within the pH 4.8 to 8 range increasing the concentration of either phosphorus, calcium, or casein increased the titration, while citrate concentration had very little effect. In the pH 6.6 to 8 range increasing the phosphate or citrate increased the titration, while increased calcium or casein slightly decreased it. Apparently each of the constituents has a decided effect on the equilibrium and changes the formation of the titration curve in a manner which cannot be predicted from its individual curve.

II. *The "buffer curves" of milk.*—In the second study typical buffer curves are presented for solutions of phosphate, citrate, and casein, and a combination of the three, in comparison with the normal milk curve and the curve for a solution containing calcium in addition to the first three constituents. The two latter curves practically coincide and are very dissimilar to the former group, indicating the pronounced effect of calcium on the titration. Other curves show the relation of milk and acid whey, with the conclusion that the differences are due to the influence of casein on the calcium phosphate equilibrium. The study emphasizes the interdependence of the buffers phosphate, citrate, casein, and calcium.

Some factors influencing the acidity of freshly drawn cows' milk, W. J. CAULFIELD and W. H. RIDDELL (*Jour. Dairy Sci., 19 (1936), No. 4, pp. 235–242, fig. 1*).—The Kansas Experiment Station made a study of the titratable acidity of freshly drawn milk from all cows in the station herd over a 14-mo. period.

The average acidity was 0.16, 0.161, 0.172, and 0.179 percent for Ayrshires, Holsteins, Guernseys, and Jerseys, respectively, with 80 percent of the samples of any one breed falling within a range of 0.06 percent. The colostrum milk was high in acidity and declined rapidly for the first few milkings with a more gradual decline for the first 15 to 20 days. The acidity was quite constant from the second to the seventh month of lactation, with a marked drop observed during the last month of the lactation period. Average variations from day to day or from milking to milking were not significant.

A statistical examination of the interrelationship and variability of plate count, presumptive coliform content, and keeping quality of raw milk, H. BARKWORTH (*Jour. Dairy Res. [London], 6 (1935), No. 1, pp. 26–48, figs. 3*).—A linear relationship is noted between plate count and keeping quality, but nonlinearity occurs in those relationships concerning coliform content. In general it appears that the variability is too great for practical purposes to permit the forecasting of either term from results of the other two.

An aerobic acid-fast Actinomyces in cow's milk due to an udder infection, J. D. A. GRAY (*Jour. Dairy Res. [London], 6 (1935), No. 1, pp. 49–55, figs. 3*).—The author reports on the isolation of a pure culture of *Actinomyces*, not previously described, which was secured from an abscess developing in a guinea pig inoculated with milk from the infected bovine udder. The morphology, stain

reaction, culture, heat resistance, and pathogenicity of the organism are presented.

Results of bacteriological survey of milk jugs and milk bottles, S. V. LAYSON, E. G. HUFFER, and J. M. BRANNON (*Milk Plant Mo., 25 (1936), No. 2, pp. 34–36, 90*).—This survey of milk-distributing plants in Illinois showed wide variation in the sanitary condition of milk jugs and milk bottles, not only in the different plants but within a single plant, and with only a few showing uniformly low counts in all milk containers. Thirty percent of all milk jugs and 14.5 percent of all bottles examined showed the presence of gas-forming organisms, while only 35.6 percent of the jugs were sufficiently clean to have added only one bacterium or less per cubic centimeter of capacity.

An inquiry into the design, operation, and efficiency of pasteurising plants, A. W. SCOTT and N. C. WRIGHT (*Hannah Dairy Res. Inst. Bul. 6 (1935), pp. 72, figs. 15*).—This is a report of a survey of 19 pasteurizing plants using "holding" type pasteurizers.

The discussion covers the design and operation of pasteurizing plants, with particular reference to the types of heaters and the mechanism for holding, the treatment of milk subsequent to pasteurization, and the bacteriological control of the plants. Appendix sections show the efficiency of pasteurizing in the different plants in relation to the destruction of *M[ycobacterium] tuberculosis* and the phosphatase tests as a means of detecting inefficient pasteurization.

Effect of a milk plant quality program on the price paid to producers for milk, V. C. MANHART (*Indiana Sta. Bul. 404 (1936), pp. 12, figs. 2*).—A milk plant using a milk quality program was studied over a period of 4 yr. to determine the equitableness of the program to producers. The program was based on a grading system determined by flavor, the methylene blue test, and the sediment test.

Payments for premium grade increased from 28 percent of the total payments made the first year to 64.3, 63.3, and 66.2 percent, respectively, in the succeeding years. The producers received an average yearly net return for the 4-yr. period of 4.65 ct. more per pound of milk fat for premium grade milk than the average prevailing competitive price in the same milk area, while regular grade milk was 0.35 ct. higher and low grade milk 3.87 ct. lower. The milk plant had an average cost of 2.32 ct. more per pound of milk fat under the program than if it had purchased the milk at market price, and the additional cost did not include the expense of operating the program.

New producers admitted to the market after the first year of the program received the highest premium payments, while the second highest payments were received by the producers who sold milk during the entire period. Premium grade payments according to seasons were (1) autumn, 72.8 percent; (2) winter, 85.6; (3) spring, 75.4; and (4) summer, 29.9 percent. Undesirable flavors became important during the months of April to September and reached a peak of 9.3 percent of the total volume of milk in August. The results showed that the program was equitable to all producers and decidedly advantageous to a large majority of them.

Milk quality improvement effected at the farm by a plant program, V. C. MANHART and A. V. MOORE (*Indiana Sta. Bul. 405 (1936), pp. 16, figs. 3*).—Continuing the above study, it was found that the program effected a decided improvement in the quality of the milk as shown by the tests employed. The payment of a premium for first grade milk with proper price differentials between grades was responsible for the improvement.

Of the 14 producers who sold milk during the entire period of observation, the seven with the poorest quality at the beginning increased their average score 20.8 points and attained a quality equal to the other seven, who increased their

score only 7.9 points. The producers who sold milk from the beginning had a product superior in quality to those who quit before the end. The poorest quality milk was sold by the producers who quit during the first year of the program. The sediment test was responsible for 58 percent of the increase in total score, while the methylene blue test accounted for 42 percent.

As a result of the program, the milk plant received a better quality milk, which sold for 1 ct. higher per quart than the prevailing price for pasteurized milk. The consumer received a good quality milk of pleasing flavor with a total bacterial count of less than 10,000 per cubic centimeter after pasteurization and at the time of delivery, and the producer received a premium of about 4.5 ct. per pound of milk fat over the prevailing price paid in the territory.

The neutralisation of cream for butter-making, W. J. WILEY (*Jour. Dairy Res. [London], 6 (1935), No. 1, pp. 91–102, figs. 4*).—This discusses the theoretical aspects of cream neutralization with reference to acid base equilibria.

Experimental results are presented to show that when milk of lime is the neutralizer, pasteurization has little effect on the pH or titratable acidity of the cream. The degree of reduction in acidity due to lime neutralization as compared with the theoretical reduction, based on sodium hydroxide titration, is lowest at a pH range of 5.6 to 5.8. It gradually increases until 6.5 is reached, beyond which the two follow parallel courses.

When sodium bicarbonate is used as the neutralizer the loss of carbon dioxide has a pronounced influence on the degree of neutralization. With flash pasteurization there was practically complete neutralization, while with raw cream of low acidity neutralization was less than 50 percent of the theoretical.

Variations in pH titratable acidity relationship of cream neutralized with calcium hydroxide and sodium bicarbonate are defined.

Observations on the freezing of milk and cream.—II, The destruction of the fat emulsion in frozen cream, F. J. DOAN and F. B. BALDWIN, JR. (*Jour. Dairy Sci., 19 (1936), No. 4, pp. 225–233, figs. 4*).—Continuing this series of studies at the Pennsylvania Experiment Station (E. S. R., 74, p. 690), samples of pasteurized cream containing 40 and 25 percent of fat and 40 percent of fat plus 10 percent of sucrose, respectively, were frozen in 2-qt. containers in still air at —23° to —28° C. After complete solidity was reached the amount of fat de-emulsified amounted to 80 percent, 30 percent, and 15 percent for these respective samples.

A marked similarity was noted between the percentage of fat de-emulsified and the maximum pressure developed within the mass during freezing. The fat aggregates developed in freezing appeared identical with those developed by churning. The stability of the proteins in cream when frozen is a minor factor in aiding or preventing de-emulsification of the fat.

Effect of lipolysis on the churnability of cream obtained from the milk of cows in advanced lactation, V. N. KRUKOVSKY and P. F. SHARP (*Jour. Dairy Sci., 19 (1936), No. 4, pp. 279–284*).—This experiment from the [New York] Cornell Experiment Station demonstrated that the difficult churning and abnormal foam formation from the milk of cows in advanced lactation can be practically prevented by the pasteurization of the milk or cream shortly after it is produced, and that less difficulty is encountered when the cream is separated when warm rather than when fat globules are in a solid state. This abnormal condition of milk is probably due to the presence of fatty acids and soaps resulting from lipolytic action, and the difficulty of churning is not only affected by the accumulated fatty acids but also by the rapid increase in fat hydrolysis during the churning process.

A study of fat splitting and casein digesting bacteria isolated from butter, C. N. STARK and B. J. SCHEIB (*Jour. Dairy Sci., 19 (1936), No. 3, pp.*

191–213).—The [New York] Cornell Experiment Station has made a study of those organisms which could be isolated from butter which possess the ability to hydrolyze milk fat, split tributyrin, or decompose the casein of milk. A total of 486 cultures of bacteria was isolated from butter made and stored under controlled conditions. The organisms were grouped as follows: Gram-negative rods, 39 percent; Gram-positive cocci, 31; Gram-positive, aerobic, spore-producing rods, 15; Gram-negative micrococci, 8; Gram-positive sarcina, 5; and Gram-positive, nonspore-producing rods, 2 percent. The first-named group regularly occurred in all butters tested and except the second and third groups in large enough numbers to be of probable significance in the spoilage of butter.

Tables are presented to show various physiological reactions of the different groups. New names are suggested, and the morphological and physiological properties are summarized for five species of bacteria.

The effect of certain factors upon the keeping quality of butter, E. S. GUTHRIE, B. J. SCHEIB, and C. N. STARK (*Jour. Dairy Sci., 19 (1936), No. 4, pp. 267–278*).—In this study from the [New York] Cornell Experiment Station the effect of natural milk enzymes, bacteria, acid, and salt on the keeping quality of butter was determined from a total of 576 samples made and stored under known and controlled conditions.

Milk enzymes having a harmful effect were not destroyed by pasteurization at 145° F. for 30 min., but were destroyed at 165° for the same period. Such enzymes are not inhibited by salt but were definitely inhibited by pH 4.7 or less. Pasteurization at 165° for 30 min. destroyed all bacteria of importance in butter spoilage, and the action of both salt and acid definitely inhibited bacterial growth. In the absence of other spoilage factors a direct correlation seemed to exist between the number of fat-splitting and casein-digesting bacteria and the keeping quality of the butter. The presence of either acid or salt or the combined action of the two exerted a deteriorating effect.

Use of hydrogen ion determination on young cheese in predicting acid development in Cheddar cheese during storage, D. W. SPICER and L. H. BURGWALD (*Natl. Butter and Cheese Jour., 26 (1935), No. 21, pp. 14, 16, 33, 34*).—In a study at Ohio State University both titratable acidity and H ion were determined at various stages of manufacture in several lots of American cheese made under known and controlled conditions, and pH determinations were made on these as well as a large number of commercial cheeses during the third to tenth day of storage.

No apparent advantage was found in using pH determinations instead of the common titration test for determining acid during manufacture. There is a close relation between the degree of acidity at the time of milling and the amount of acid that develops during storage, and pH determinations made on the cheese from the third to the tenth day in storage give an accurate indication of the acidity which will ultimately develop in storage. A pH of 5.07 was about the dividing line between cheese that did or did not develop acid during storage.

Bitter flavor in Cheddar cheese, W. V. PRICE (*Jour. Dairy Sci., 19 (1936), No. 3, pp. 185–190, fig. 1*).—The Wisconsin Experiment Station has made a study of 178 lots of experimental cheese, 37 of which were adjudged as having a bitter flavor. This lot was found to have several characteristics in common with those developing a slight overacidity, leading to the conclusion that bitter flavor is associated with this condition. Further study has shown that a high correlation exists between the acidity of the curd either at the time of cutting, dipping, or milling and the pH value of the cheese at 3 days of age. Limiting the development of acidity during the curd-making operations should result in a lower incidence of bitter flavor in cheese.

VETERINARY MEDICINE

[Report of work in veterinary medicine by the Indiana Station] (*Indiana Sta. Rpt. 1935, pp. 59–63*).—The work of the year referred to (E. S. R., 73, p. 236) includes studies of the death loss in newborn pigs, the relation of fungus development on cornstalks and grain to livestock poisoning, encephalitis in horses, immunization studies of Bang's disease and of brucelliasis in bulls, the agglutination test for Bang's disease, and diagnoses made of animal diseases.

[Parasites of domestic animals in Puerto Rico] (*Puerto Rico Sta. Rpt. 1935, pp. 23–26*).—Included in this report (E. S. R., 73, p. 537) is a host list of the lice infesting domestic animals, including birds, in Puerto Rico and in the continental United States and a similar host list of the parasitic mites. Reference is made to several new protozoan parasites of domestic animals reported from Puerto Rico for the first time, particularly Coccidia, mention being made of *Eimeria faurei* in the goat. Reference is also made to several diseases limiting Puerto Rican poultry production, which include coccidiosis and blackhead; to the brown dog tick as the only vector of piroplasmosis of dogs, the chronic form of which has been encountered; and to anaplasmosis in cattle.

Ectoparasites of domestic animals observed in the State of São Paulo [trans. title], Z. Vaz (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 29–33; Eng. abs., p. 33*).—A host list is given of the ectoparasites of domestic animals in the State of São Paulo, Brazil, presented with 15 references to the literature.

An attempt to transmit anaplasmosis by biting flies, H. Morris, J. A. Martin, and W. T. Oglesby (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 169–175*).—In work at the Louisiana Experiment Station, 3 animals that were exposed to intermittent feeding of the black horsefly failed to develop the disease in 80 days. One preliminary test with this fly proved positive in 25 days. Three animals exposed to intermittent feeding of the horn fly failed to develop the disease in 100 days. Three animals exposed to intermittent feeding of *Tabanus fuscicostatus* Hine failed to develop the symptoms in 80 days. All 9 exposed animals were known to be susceptible because all developed the disease when given intravenous injections of virulent blood. No attempt is made to explain why these results are different from those reported from Oklahoma (E. S. R., 67, p. 453) and Florida (E. S. R., 70, p. 530).

Transmission of Aujeszky's disease to the rabbit by the external auditory canal [trans. title], P. Remlinger and J. Bailly (*Compt. Rend. Soc. Biol. [Paris], 119 (1935), No. 24, pp. 937–939*).—Two experiments reported have shown the virus of Aujeszky's disease to be transmissible through the external auditory canal, in addition to the nares, conjunctiva, and rectum, and by ingestion as previously demonstrated.

Vitamin G from different sources and coccidian infection, E. R. Becker and N. F. Morehouse (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 4, pp. 437–439*).—The experiments reported, conducted with *Eimeria miyairii* on rats, have shown that coccidium growth is tied up with the vitiman G complex. When yeast or certain other materials are employed as a source of this vitamin, the growth of this parasite is stimulated. Liver as a source of the vitamin does not favor the development of the coccidian.

Inoculability of certain neurotropic viruses (herpes, poliomyelitis) by the external auditory canal [trans. title], C. Levaditi and J. Vieuchange (*Compt. Rend. Acad. Sci. [Paris], 200 (1935), No. 21, pp. 1800, 1801*).—The three experiments reported have shown that it is possible to produce a herpetic encephalitis in the rabbit by depositing a suspension of the virus in the external auditory canal.

Inoculability of certain neurotropic viruses (herpes, in particular) by the external auditory canal [trans. title], C. LEVADITI and J. VIEUCHANGE (*Compt. Rend. Soc. Biol. [Paris], 119 (1935), No. 24, pp. 949–951*).—A further contribution supplementing that above noted.

Onchocerciasis, with special reference to the Central American form of the disease (*Cambridge, Mass.: Harvard Univ. Press, 1934, pp. XIV+234, pls. [9], figs. [101]*).—Part 1 of this work, by R. P. Strong, deals with onchocerciasis, with special reference to the Central American form of the disease (pp. 1–132); part 2, by J. H. Sandground, considers the validity of the various species of the genus *Onchocerca* Diesing (pp. 133–172); part 3, by J. C. Bequaert, consists of notes on the blackflies or Simuliidae, with special reference to those of the *Onchocerca* region of Gua'emala (pp. 173–224); and part 4, by M. Muñoz Ochoa, presents some epidemiological facts about the onchocerciasis of Guatemala (pp. 225–234). Quite complete bibliographies are included in the first three contributions.

It is pointed out by Sandground that the genus *Onchocerca* was created by Diesing in 1841 for a parasite, to which the name *O. reticulata* was given, found in the suspensory ligament of the fetlock of a horse in Wien (Vienna), Austria. A catalog which is given of the species assigned to the genus, 14 in number, includes 2 from the equine, namely, *O. reticulata* and *O. cervicalis;* 6 from bovines, namely, *O. armillata, O. lienalis, O. gutturosa, O. gibsoni, O. indica,* and *O. bovis; O. flexuosa* from the antelope; *O. fasciata* from the camel; 2 from man, namely, *O. volvulus* and *O. caecutiens; O. fuelleborni* from *Neomeres phococoenoides;* and *O. bambusicolae* from *Bambusicola thoracica.*

Antigenic studies on the genus Pasteurella, G. C. BOND and C. M. DOWNS (*Kans. Acad. Sci. Trans., 38 (1935), pp. 87–92*).—In the studies reported no suitable method of classification based on cultural characteristics of members of the genus *Pasteurella* could be determined. "The weak antigenic properties of these organisms as previously reported was verified. Much cross-serological relationship was evident between the animal strains of *Pasteurella* used. No correlation between host origin and antigenic structure was apparent. No satisfactory method of grouping these organisms into subgroups could be devised. [Neither *P. tularense* nor *P. pestis* has any] serological relationship to other members of the genus. A definite serological relationship exists between *P. tularense* and *B[ruccila] abortus* which is not found with other members of *Pasteurella.*"

Hemolytic streptococci from tonsils of cow, hog, and sheep, I. PILOT, C. BUCK, and D. J. DAVIS (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 2, pp. 233–235*).—The authors have found that hemolytic streptococci frequently occur in the crypts of the tonsils of the cow (84 percent), hog (96 percent), and sheep (74 percent). They constitute part of the normal flora of the lymphoid tissue of the oropharynx of these animals. The streptococci conform to the animal type and differ from the human type and the *Streptococcus epidemicus* of bovine mastitis and epidemic septic sore throat.

Fibrinolytic activity of beta hemolytic streptococci from cow's milk, F. R. SMITH, C. L. HANKINSON, and C. S. MUDGE (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 2, pp. 266–270*).—The work reported has shown that (1) some beta hemolytic streptococci from milk are capable of causing the lysis of clotted bovine plasma, and (2) organisms from cows that are negative to nonspecific tests for mas'itis may produce this fibrinolysis.

The development of natural and artificial resistance of young rats to the pathogenic effects of the parasite Trypanosoma lewisii, C. A. HERRICK and S. X. CROSS (*Jour. Parasitol., 22 (1936), No. 2, pp. 126–129*).—This is a

contribution from the Wisconsin Experiment Station and the U. S. D. A. Bureau of Animal Industry cooperating.

The pathology of Crotalaria spectabilis Roth poisoning in cattle, D. A. SANDERS, A. L. SHEALY, and M. W. EMMEL (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 150–156*).—In a further study of *C. spectabilis* poisoning at the Florida Experiment Station (E. S. R., 72, p. 605), the "clinical symptoms, gross and microscopic lesions occurring in a herd of cattle under natural conditions were reproduced in animals experimentally by daily oral administration of pulverized *C. spectabilis* seed. *C. spectabilis* poisoning, as observed in cattle under natural conditions, assumed a chronic form with gradual onset unaccompanied by clinical manifestations in the beginning. Clinical symptoms in cattle grazing daily on crotalaria for 2 weeks developed after a latent period of from 2 to 6 mo. These consisted of impaired appetite, diarrhea, ascites, acute bloating, decubitus, and tenesmus, with partial eversion of the rectum.

"At autopsy there were observed hydroperitonia; a firm, resistant, indurated liver; enlarged gall bladder; icterus; congestion of the kidneys; congestion, edema, and emphysema of the lungs; edematous infiltration of the submucous layer of the abomasal folds and of the subserous coverings of the double elliptical coils of the colon; with hypertrophy of the cardiac muscle.

"Microscopically there was observed a diffuse inter- and intra-lobular fibrosis, atrophic degeneration, and pigmentation of the hepatic parenchyma; fibrosis of the spleen; parenchymatous degeneration and fragmentation of the renal epithelium; connective tissue proliferation, edema and emphysema of the pulmonary tissues; and parenchymatous degeneration and epithelial exfoliation of the mucous membrane of the intestinal tract."

Oak poisoning in range cattle and sheep, I. B. BOUGHTON and W. T. HARDY (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 157–162*).—Several outbreaks of highly fatal poisoning among range sheep and cattle observed by the Texas Experiment Station resulting from the eating of the buds, green shoots, and young leaves of the common shin oak (*Quercus breviloba*), which occurs in abundance on the ranges of the Edwards Plateau region of western Texas, are reported upon. Following a brief reference to the literature, investigations of the cause, course, symptoms, post-mortem lesions, and treatment and prevention are dealt with.

The disease ran a fairly acute course, a few animals having died within 24 hr. after manifesting symptoms, but with the majority the symptoms appeared from 5 to 10 days before succumbing. Some chronically affected animals lingered for more than a month. Complete recovery of either cattle or sheep seldom occurred under 2 or 3 weeks. The mortality of affected animals averaged about 85 percent in cattle and 90 to 95 percent in sheep.

No efficient means of treatment was found. Prevention of the condition should provide for the separation of the animal and the shin oak during the period when the buds and young leaves are apparently very toxic.

Inhibiting effect of sulphur in selenized soil on toxicity of wheat to rats, A. M. HURD-KARRER and M. H. KENNEDY (*Jour. Agr. Res. [U. S.], 52 (1936), No. 12, pp. 933–942, figs. 4*).—In experiments conducted, "wheat grown on soil containing 2 p. p. m. of selenium and comprising 70 percent of the diet of white rats produced the retarded growth and the liver injury characteristic of selenium poisoning. Wheat grown on similarly selenized soil treated with flowers of sulfur or with gypsum was not toxic. Chemical analysis of the grain showed that the sulfur and gypsum treatments reduced the concentration of selenium in the grain from about 12 p. p. m. to about 4 p. p. m."

Studies in Brucella infections (*Michigan Sta. Tech. Bul. 149 (1936), pp. 51*).—This consists of reports of five separate studies.

Non-specific agglutination in the Brucella group, I. F. Huddleson, J. W. Scales, and O. J. Sorenson (pp. 5–20).—The results obtained from the examination of a total of 410 strains of *B. abortus*, 240 strains of *B. suis*, and 140 strains of *B. melitensis*, by means of the thermoagglutination test of Burnet (E. S. R., 60, p. 870) over a 3-yr. period, show conclusively that the phenomenon is mutable in character and, once its occurrence has been demonstrated in a strain, it usually occurs again. Partially or completely dissociated strains of *Brucella* were found unreliable as antigens for the agglutination test. There are long intervals during which dissociated strains are heat stable. The thermoagglutination test serves only as an approximate means of detecting rough and dissociated variants of *Brucella*. It cannot be depended upon entirely as a routine test for the selection of normal cultures for use as antigens in the agglutination test. There is partial evidence that heat instability is due to changes in the chemical composition of the cell and to a rearrangement of certain chemical constituents.

"It has been noted that agar agglutination and thermoagglutination of *Brucella* cells are two entirely separate and distinct phenomena. The heating of a suspension of *Brucella* cells, to which dissolved agar has been added, to a high temperature in order to obtain agglutination of the cells is not necessary except when the agar is present in a high dilution. The presence of dissolved agar in a high dilution in *Brucella* antigens does not materially affect its specific agglutinating property."

A list of 22 references to the literature is included.

The chemical examination of an avirulent strain of Brucella abortus, A. D. Hershey and I. F. Huddleson (pp. 21–23).—In this contribution the occurrence and properties of various cellular fractions of an avirulent strain of *B. abortus* are described, and comparisons with the composition of normal strains are made. The principal differences were found to consist in serological dissimilarities between the protein fractions and in the absence in the nonpathogenic strain of a conjugated protein constituent which is largely responsible for the toxicity and serological properties of the virulent strain.

A study of Brucella abortus-infected tissues as immunizing agents against Brucella infection in the guinea pig, J. W. Scales and I. F. Huddleson (pp. 24–27).—In a study aimed at the determination of the value of *B. abortus* infected tissue as an immunizing agent against *Brucella* infection in the guinea pig, the spleens of infected guinea pigs and infective fetal exudate from fetal membranes treated to render them noninfective were studied. "The results show conclusively that when infected guinea pig spleen and exudate from the fetal membranes of an aborted bovine fetus are treated with either chloroform or formalin to render them noninfective, they are without value as immunizing agents against experimental *B. abortus* infection in the guinea pig."

A method for measuring the opsonocytophagic power of the blood of cattle for Brucella, I. F. Huddleson, H. W. Johnson, and D. B. Meyer (pp. 28–34).—A method for determining the degree of immunity in cattle against *Brucella* infection is described. It involves the measuring of the phagocytic power of the polymorphonuclear leucocytes in an opsonocytophagic system.

Undulant fever: A report of 100 cases treated with brucellin, I. F. Huddleson, H. W. Johnson, and C. P. Beattie (pp. 35–51).—Following the preliminary report on the value of brucellin therapy in undulant fever (E. S. R., 70, p. 529), a more extensive study was made of the product on a wide variety and type of

cases, mainly to learn more about its therapeutic value, and is here reported upon. Summarized data are presented which show the value of brucellin in the treatment of 100 cases of undulant fever. Of the total number of cases dealt with, 23 were children under 11 yr. of age.

"Of the 70 cases in which the duration of symptoms was less than 121 days before treatment with brucellin, 51 (73 percent) recovered within 22 days after the first injection, 18 (26.1 percent) after the 22-day period, and 1 (1.4 percent) failed to respond to treatment. Of the 30 cases in which the duration of symptoms was more than 120 days before treatment, 17 (56.6 percent) recovered within 22 days after the first injection, 10 (33.3 percent) recovered after the 22-day period, 2 terminated fatally, and 1 failed to respond to treatment. If one excludes the 6 cases that failed to respond to treatment and the 2 that succumbed, it will be found that the average duration of illness per case before treatment was 159.3 days. The average duration of illness per case after treatment was begun was 18.3 days.

"The serum agglutination titer was either negative or less than 1–50 in 33 cases. Of the 33 cases, 22 (66 6 percent) were children under 11 yr. of age. Positive blood cultures were obtained in only 16 of the 85 cases cultured. Of the 16, 7 were *B. abortus*, 5 were *B. suis*, and 4 were *B. melitensis*. An allergic test made intradermally with a standardized allergin and a proved opsonocytophagic test carefully conducted are indispensable for the accurate diagnosis of a large percentage of cases of brucelliasis. The latter test may also be used in determining recovery from the disease."

Reaction-frequency in Denmark and Finland for abortus-infection in cattle, A. THOMSEN and V. RISLAKKI (*Skand. Vet. Tidskr., 26 (1936), No. 5, pp. 321–328: Eng. abs., pp. 327, 328*).—Agglutination tests for *Brucella abortus* infection resulted in a reaction percentage of from 21.5 to 35.4 for more than 1,000 blood samples made in Denmark and 3.5 to 14.3 for a similar number made in Finland.

The effect of Brucella abortus infection of the udder on the quality of milk, C. S. BRYAN and D. B. MEYER (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 199–206*).—In work at the Michigan Experiment Station the quality of milk secreted by *B. abortus*-infected udders is decreased as compared with that from healthy udders, but the changes are not so pronounced as those found in streptococcic mastitis. *B. abortus* may cause a low-grade mastitis, as has been indicated in previous histopathological studies by Sholl and Torrey (E. S. R., 65, p. 70) and by the results of the tests employed in this study. The chemical composition of milk may be altered as a result of *B. abortus* infection of the udder.

Experimental vaccination of range calves with a living culture of Brucella abortus.—I, Results of agglutination tests made at intervals during three years following vaccination, W. J. BUTLER, D. M. WARREN, and H. MARSH (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 163–168, fig. 1*).—Contributing from the Montana Experiment Station the authors record the results of post-vaccination tests for *B. abortus* agglutinins in the blood serum of range heifers vaccinated with a living culture of *B. abortus* of low virulence. "These tests show that in a group of heifers vaccinated at 6 to 12 mo. of age, the agglutinins produced by vaccination were reduced in 12 mo. to the extent that no reactions occurred at a 1:200 dilution, and that at the end of 2 yr., 77 percent of the heifers were negative at 1:25 and none reacted at a dilution higher than 1:50.

"In a group of heifers in the same herd which were vaccinated at the age of 4 to 6 mo., there were no reactions at 1:200 in 8 mo., and at the end of

2 yr., 97 percent of the heifers were negative at 1:25 with no reactions higher than 1:50.

"The results of these agglutination tests also indicate that *B. abortus* did not become established in any of the heifers as a result of vaccination."

Observations pertaining to standards of interpretation of agglutination titres in the diagnosis of Bang's disease, C. R. DONHAM and C. P. FITCH (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 176–186*).—Data are given in this contribution from the Minnesota Experiment Station which indicate "the effect, from a percentage standpoint, of different standards for interpretation of agglutination results. Data are presented which disprove the idea that all agglutinating substances demonstrated in low dilutions should be considered as evidence of active infection with *Brucella abortus*. The inadequacy of inflexible standards for interpretation of agglutination results is emphasized by these data. The policy of making diagnoses of suspicious cases in Bang's disease only after careful consideration of the complete status of the entire herd is advocated."

Bang's-disease control, M. JACOB (*Tennessee Sta. Rpt. 1934, pp. 13, 14*).—The progress of control work during the year in the breeding herds at both the Middle and West Tennessee Substations is briefly referred to (E. S. R., 73, p. 236).

Bovine mastitis, W. T. MILLER (*North Amer. Vet., 17 (1936), No. 3, pp. 32–41*).—A practical summary of information presented with a list of 18 references to the literature.

Infectious bovine mastitis.—IV, The curd tension of normal and mastitis milk, E. O. ANDERSON, C. L. HANKINSON, W. N. PLASTRIDGE, and F. J. WEIRETHER ([*Connecticut*] *Storrs Sta. Bul. 211 (1936), pp. 15*).—In further work with infectious bovine mastitis (E. S. R., 73, p. 104) the three principal organisms associated with chronic mastitis—group A and group B streptococci and staphylococci—were found equally effective in reducing the curd tension of milk. "Coli-like mastitis infections decrease the curd tension to a greater extent than any of the other reported types of mastitis infections. With a leucocyte content of a million the curd tension was definitely lowered. Each additional million leucocyte count was accompanied by a further decline in curd tension. In fact this correlation was observable even when the organisms of mastitis were not found. About 65 percent of the disease-free quarters of Holsteins and Ayrshires yielded milk of low curd tension. The number of mastitis-free Guernseys and Jerseys producing natural low curd tension milk seems to be negligible.

"In mastitis-free milk a correlation coefficient of $\pm 0.9707 + 0.0138$ P. E. [probable error] was found between casein content and curd tension, while for milk from diseased udders the correlation coefficient was $+0.8125 \pm 0.810$ P. E. High casein content is associated with high curd tension. Multiple correlations between curd tension and CaO and P_2O_5 in mastitis-free milk was $+0.9120 \pm 0.0328$ P. E., while for milk from diseased udders it was $+0.6212 \pm 0.1566$ P. E."

Rennet test for the detection of mastitis, F. B. HADLEY (*Jour. Dairy Sci., 19 (1936), No. 3, pp. 165–169*).—This contribution from the Wisconsin Experiment Station describes a new milk test with fresh commercial fluid rennet for the detection of mastitis. It is believed that this method of testing, because of its simplicity and cheapness, may have practical use. Comparisons of the results secured by the rennet method with those secured by other methods are presented.

Severe ascariasis in calves, N. S. SEVILLA (*Philippine Jour. Anim. Indus., 3 (1936), No. 2, pp. 137, 138*).—A report is made of the loss of 2- to 4-week-old calves on a ranch in Zambales due to an infestation by *Ascaris vitulorum*.

Experiments on anthrax vaccination [trans. title], G. RAMON and A. STAUB (*Compt. Rend. Soc. Biol. [Paris], 119 (1935), No. 25, pp. 1073–1076; abs. in Vet. Rec., 16 (1936), No. 16, pp. 504, 505*).—The authors conclude that it is possible to confer on sheep a solid and durable immunity against anthrax by a single dose of Pasteur's first vaccine, incorporated in lanolin.

Experimental treatment of caseous lymphadenitis of the sheep and goat in the French Sudan [trans. title], MISSENARD (*Bul. Acad. Vét. France, 8 (1935), No. 6, pp. 314–319*).—The intradermal administration of a bacterin composed of cocci and staphylococci has been found the most effective and practical means of protection against caseous lymphadenitis, a coccal disease of sheep and goats of common occurrence in the French Sudan.

Prevention of death losses in sheep on areas infested with pingue (Actinea richardsoni), K. W. PARKER (*New Mexico Sta. Bul. 241 (1936), pp. 53, figs. 19*).—Experimental work with *A. richardsoni*, commonly known as pingue or the Colorado rubber plant, the cause of heavy death losses of range sheep, particularly in the northeastern portion of New Mexico, is reported, the details being given in tables and charts.

It has been found that death losses in sheep from this plant "can be reduced, if not entirely avoided, by managing the sheep in such manner that they enter pingue areas in at least fairly good physical condition after lambing; that is, it is important that they have a reserve of the necessary elements and nutrients in their bodies in order to obviate any depraved appetite that they might otherwise have when placed on pingue-infested areas. Sheep should be closely culled before entry on pingue range, so that all broken-mouthed ewes may be removed from the band. Animals exhibiting symptoms of pingue poisoning should be removed from the flock and placed on range that is not infested with this poisonous plant.

"Chemical analyses of the principal forage grasses from the pingue experimental range indicated that these approached a deficiency in calcium and phosphorus. The feeding of a mineral supplement containing calcium and phosphorus was evidently beneficial, since the weights of ewes and lambs so fed were increased over those fed salt alone.

"The bedding out system of grazing sheep, whereby a new bed ground is established every night or every 2 or 3 days in choice areas of forage, should be closely adhered to when grazing sheep on pingue-infested ranges. Sheep should not be placed on pingue range before the range is ready for grazing, as determined by close observation of the stage of growth of certain plants that indicate the proper time for grazing to begin. Loss of sheep from poisoning and injury to the range by premature grazing are both thus avoided. Death losses in sheep from pingue poisoning may occur at any time during the year, but the most dangerous times for grazing areas infested with this plant are in spring and late fall, when palatable forage is likely to be scarce.

"It is evident from observation that pingue invades most rapidly ranges which have been more or less opened up by overgrazing. Results from vegetative plats indicated that pingue can be eradicated by pulling or digging the plants, that this plant increases in area during overgrazing, and that the spread of pingue can be checked by giving the area complete protection from livestock grazing. A 25-percent aqueous solution of Atalacide applied in the form of a spray secured a 95.3-percent kill of pingue plants. However, except on small areas, the expense would be too great to make eradication of this plant by either mechanical or chemical means practical under range conditions."

A palatability and check list of the flora of Mount Taylor, Valencia County, N. Mex., is appended.

The occurrence of Syngamus in the nasal fossae of sheep in Brazil [trans. title], Z. VAZ (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 35–39, figs. 8; Eng. abs., pp. 38, 39*).—The occurrence of *Syngamus* in the nasal cavities of sheep in São Paulo is recorded. The author failed to find *S. nasicola* to differ specifically from *S. laryngeus* of cattle. The great variations presented by *S. laryngeus* appear to be accentuated by the different locations in the host.

Mass feeding of sheep with copper sulphate and salt to control gastro-intestinal parasites, J. H. RIETZ (*West Virginia Sta. Bul. 271 (1936), pp. 11*).—Experiments with sheep here reported indicate that "the mixture of copper sulfate and salt, 1:30, when fed to sheep ad libitum and consumed at the rate of 0.5 lb. per sheep per month, did not adequately control the development of nematode parasites in the gastrointestinal tract, yet caused the death of sheep from poisoning. A mixture of copper sulfate and salt, 1:50, was wholly inadequate in controlling nematode parasites in the gastrointestinal tracts of these sheep. The 1.5-percent solution of copper sulfate and the mixture of equal parts of a 1.5-percent solution of copper sulfate and a 1.5-percent solution of nicotine sulfate were equally efficient in the control of nematode infestation. Cestode infestation also disappeared equally under the two treatments."

Infectious pleuropneumonia of goats: Experimental behavior of a virus isolated from the central nervous system, J. TRAVASSOS (*Compt. Rend. Soc. Biol. [Paris], 121 (1936), No. 11, pp. 1121, 1122*).—The author reports having isolated a filtrable virus from the brain and spinal cord of enzootic cases among native and imported goats, which proved to be pathogenic for the guinea pig and rabbit, as well as the goat, among the animals thus far inoculated. The autopsy of infected goats revealed pulmonary lesions, representing several forms of pneumonia.

Anomalous urinary system in a small pig, J. F. BULLARD (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 220, 221, fig. 1*).—Contributing from the Indiana Experiment Station a description is given of an anomalous urinary system found in a small 8-week-old Chester White male pig which weighed approximately 20 lb.

Immunization experiments with swine influenza virus, R. E. SHOPE (*Jour. Expt. Med., 64 (1936), No. 1, pp. 47–61*).—The author reports upon further experiments (E. S. R., 74, p. 394) conducted in an effort to determine the effect of dosage, route of administration, and animal source upon the efficacy of swine influenza virus in immunizing swine, ferrets, and mice. The swine influenza virus obtained from the lungs of infected ferrets or mice, when administered intramuscularly or subcutaneously, was found to immunize the swine to swine influenza. "Ferrets which have received subcutaneous injections of swine influenza virus obtained from the lungs of infected ferrets are immune to intranasal infection with this virus. Similar injections with virus from the lungs of infected mice or swine do not immunize. Mice can be immunized to intranasal infection with swine influenza virus by the subcutaneous injection of virus obtained from the lungs of infected mice, but not by similar injection with virus from the lungs of infected ferrets or swine. Repeated injections induce greater immunity than a single one. Intraperitoneal inoculation of both mice and ferrets with swine influenza immunizes them to intranasal infection, and it appears to make little or no difference whether the virus used as vaccine is obtained from the lungs of infected mice, ferrets, or swine. Field experiments in which swine influenza followed the intramuscular administration of virus are cited as examples of the hazard involved in the use of this means of immunization in a densely crowded susceptible population."

Notes on the preparation and use of an antigen for the agglutination test in swine erysipelas, A. W. DEEM (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 197, 198*).—Beef infusion broth containing yeast and tryptophan was found to provide an excellent medium for the growth of *Erysipelothrix rhusiopathiae* as the antigen in the agglutination test in swine erysipelas. A method is described for the preparation of an antigen that stays in suspension so that the test may be read after incubation for 24 hr.

Adaptation of Stichorchis giganteus, a parasite of peccaries (Dicotyles spp.), to the domestic pig: A redescription [trans. title], Z. VAZ (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 45–52, figs. 7; Eng. abs., p. 51*).—The occurrence of *S. giganteus* Diesing 1835 in the domestic pig in São Paulo, Brazil, is reported and a redescription given based upon material from this host.

Transmission of the virus of equine encephalomyelitis through Aedes albopictus Skuze, J. S. SIMMONS, F. H. K. REYNOLDS, and V. H. CORNELL (*Amer. Jour. Trop. Med., 16 (1936), No. 3, pp. 289–302*).—The experiments here reported have shown that the virus of equine encephalomyelitis, western type, can be transmitted biologically from infected to normal animals through *A. albopictus*, a common, semidomestic, oriental mosquito.

Further studies on transmission of equine encephalomyelitis by mosquitoes, D. E. MADSEN, G. F. KNOWLTON, and J. A. ROWE (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 187–196*).—In further experimental work by the Utah Experiment Station (E. S. R., 73, pp. 108, 393; 74, p. 235), "the period of transmissibility of equine encephalomyelitis virus in *Aedes nigromaculis* varied between 4 and 10 days, with the peak at 6, 7, and 8 days. In *A. dorsalis* the period varied between 9 and 19 days, with 12, 13, and 14 days as the most likely choice of a peak. The period of virus availability in the donor for *A. nigromaculis* was between 18 and 66 hr., inclusive. In *A. dorsalis* the period was from 18 to 42 hr., inclusive. A limited number of attempts to transmit the disease to horses by means of these two native mosquitoes were unsuccessful."

The seat of the virus of Argentine equine encephalomyelitis (experimental disease) [trans. title], R. REMLINGER and J. BAILLY (*Compt. Rend. Soc. Biol. [Paris], 121 (1936), No. 5, pp. 429–431*).—Inoculation experiments with emulsions of tissues from infected animals have shown the Argentine virus of equine encephalomyelitis to occur in the parotid and adrenal glands but not in the urine of the infected horse, rabbit, or guinea pig. It may be present in the blood.

Inoculability of the Argentine virus of equine encephalomyelitis by the external auditory canal [trans. title], B. REMLINGER and J. BAILLY (*Compt. Rend. Soc. Biol. [Paris], 121 (1936), No. 10, pp. 933, 934*).—Two transmission experiments with the rabbit and guinea pig here reported have shown the virus of Argentine equine encephalomyelitis to be transmissible by way of the external auditory canal, as has previously been shown by Levaditi and Vieuchange (see p. 840) to be the case with herpes-encephalitis, and by the authors with Aujeszky's disease (see p. 840).

Pure cultivation of filtrable virus isolated from canine distemper.—II, Morphological and cultural features of Asterococcus canis, type I, n. sp. and Asterococcus canis, type II, n. sp., H. M. SHOETENSACK (*Kitasato Arch. Expt. Med. [Tokyo], 13 (1936), No. 2, pp. 175–183, pls. 2*).—In continuation of the study previously noted (E. S. R., 72, p. 536), a description is given of the micro-organism isolated under the name *A. canis* n. sp, of which there are two types. Type 1 is considered to be the true cause of the contagious respira-

tory type of canine distemper; type 2 appears to play a secondary part in the etiology of the disease.

A case of suppurative epididymitis in a dog caused by Brucella abortus, T. L. WHITBY, T. J. BOSWORTH, and J. R. M. INNES (*Vet. Rec., 48 (1936), No. 21, pp. 662, 663, 664*).—A case report of infection in the dog.

Infectious rhinitis (coryza) (*Rhode Island Sta. Rpt. [1935], p. 32*).—Reference is made to the progress of work during the year with *Hemophilus gallinarum* as related to infectious coryza of poultry (E. S. R., 73, p. 689).

Massachusetts poultrymen successful in maintaining pullorum disease-free flocks, H. VAN ROEKEL (*New England Poultryman and Northeast. Breeder, 22 (1936), No. 3, p. 37*).—This contribution from the Massachusetts Experiment Station refers briefly to the progress of pullorum disease eradication work in Massachusetts (E. S. R., 74, p. 400).

Tuberculosis of poultry, A. J. DURANT (*Missouri Sta. Bul. 364 (1936), pp. 22, figs. 10*).—A practical summary of information of this disease of poultry and its control and eradication.

Naphthalene poisoning in poultry, C. B. HUDSON (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, p. 219*).—A report on the loss of poultry from the ingestion of naphthalene moth balls placed in the nests for protection from lice and mites is contributed from the New Jersey Experiment Stations. "The symptoms observed in the birds presented were identical. Their combs were red and their eyes bright. There was a partial paralysis of the legs. The feathers around the vent were soiled with greenish black fecal material. On autopsy the hen [presented for examination] showed the following changes: There were small blisterlike areas in the mucosa of the crop. The liver was swollen and showed small necrotic areas. The intestines were catarrhal, and the gizzard contents gave off a strong odor of naphthalene."

The avian spirochetoses [trans. title], J. VERGE (*Rec. Méd. Vét., 112 (1936), No. 5, pp. 257–270*).—A summary of information on spirochetosis of the fowl due to *Spirochaeta gallinarum* and of the goose due to *S anserina*, with a brief reference to other avian spirochetoses.

Blackhead (infectious enterohepatitis) in turkeys, with notes on other intestinal protozoa, H. M. DEVOLT and C. R. DAVIS (*Maryland Sta. Bul. 392 (1936), pp. 493–567, figs. 15*).—The studies reported have shown that blackhead is not regularly, if ever, transmitted through the egg. It has been controlled consistently by incubator hatching and rearing poults in isolation from adult turkeys or chickens or soil contaminated by such birds. The parasite (*Histomonas meleagridis* Tyzzer) has been found to be present in the breeder yard as shown by the appearance of the disease in poults hatched by the turkey hen. The mortality rate in such young birds has varied between 33 and 76 percent of the hatch. The most frequent time of death in these poults has been during the second month of their life, but deaths from blackhead have occurred at earlier and later dates during the growing period as well. Blackhead has also appeared in the grown turkeys, most commonly causing the death of young hens in heavy egg production. The causative parasites have also been found in the chicken yard, as young turkeys have readily contracted the disease when reared under those conditions.

"The presence of blackhead parasites has been demonstrated in contaminated soil, as shown by the appearance of the disease in young turkeys placed in experimental pens on top soil taken from the turkey breeder or chicken yards. Such experiments have furthermore indicated that deaths may occur in from 2 to 3 weeks after young turkeys are exposed in this way to the disease. Experiments

conducted on the problem of fly transmission have indicated that flies may be regarded with suspicion as carriers of blackhead.

"The transmission of blackhead by inoculations with material taken from the affected internal organs has made possible the isolation and identification of the causative parasite. Tyzzer's 'inoculated' blackhead [E. S. R., 43, p. 885] has been reproduced by placing small pieces of affected liver tissue beneath the skin, and a new form of blackhead has resulted from the implantation of such material in cavities of the head.

"The isolation of the blackhead parasite in protozoan pure culture on modified Locke's egg medium has been accomplished by feeding young turkeys with affected liver tissue and seeding the culture medium with the cecal droppings or contents obtained at autopsy. The observation of this parasite in such droppings and cultures has shown it to be identical with *H. meleagridis* Tyzzer. The feeding of the cultures to young turkeys has regularly produced blackhead. Trichomonads which were formerly held to be the causative agent of blackhead by some investigators have been found on some occasions to be present in blackhead livers. While inoculation studies with trichomonads have given rise to the belief that they may be capable of causing disease under certain conditions, it was not possible to produce blackhead lesions regularly with them.

"The parasitological and clinical periods that prevail during the course of an attack of blackhead in young poults have been studied by making inoculations with Locke's egg medium cultures of histomonads. Under the conditions of this experiment, death occurred at various times between the ninth and fifteenth day after inoculation. Symptoms of illness appeared in from 4 to 9 days after inoculation, and in all cases the affected poult voided the causative parasites in the droppings before showing symptoms of illness. It was possible to transmit the disease by feeding normal poults with fresh cecal droppings containing the histomonads"

An anatomopathological study of enterohepatitis or blackhead of turkeys [trans. title], J. R. MEYER (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 85–94, pls. 6; Eng. abs., p. 93*).—A report is made of a study of 15 spontaneous cases of blackhead in turkeys, presented with a list of 15 references to the literature.

Salmonellosis of webfooted fowl [trans. title], LESBOUYRIES and BERTHELON (*Rec. Méd. Vét., 112 (1936), No. 4, pp. 193–209*).—Following a general discussion of paratyphoid organisms and their differentiation by biochemical and serological means, an account is given of the *Salmonalla* infections of palmipeds. Salmonellosis is a disease of adult as well as young ducks and geese.

Staphylococcus infections in birds [trans. title], J. REIS and P. NOBREGA (*Arch. Inst. Biol. [São Paulo], 6 (1935), pp. 63–68, pls. 2; Eng. abs., pp. 66, 67*).—The authors' observations are presented with a review of the literature on *Staphylococcus* infection in birds, a list of 14 references to which is included.

"In São Paulo in 2,088 autopsies made in the Biological Institute we observed 6 cases of staphylococcic arthritis, 3 being in hens (in 1 case the sample was also isolated from the liver), 2 in pigeons, and 1 in a canary. The 2 pigeons were from the same loft, where the disease manifested itself simultaneously in many individuals. From a pigeon of the same origin, which died suddenly with arthritis, nonhemolytic *S. aureus* was isolated from the liver. One of the hens with arthritis presented antitoxin in the serum capable of neutralizing the toxicity of the sample for the mouse.

"In 1 hen we observed a staphylococcic abscess . . . in the superciliary region, which regressed spontaneously. In 1 case of acute spontaneous conjunctivitis, also in a hen, we isolated hemolytic *S. aureus* in abundant culture.

but by instillation of the culture we were not able to reproduce the disease in a healthy bird.

"In the skin of pigeons with the reaction of vaccination against chicken pox we frequently observed the presence of hemolytic staphylococci, which are not found normally."

The text includes a chart in which the characters of the staphylococci isolated, both from normal birds and those with pathologic manifestations, are given.

Parasitism and tuberculosis in a crow, F. R. BEAUDETTE and C. B. HUDSON (*Jour. Amer. Vet. Med. Assoc., 89 (1936), No. 2, pp. 215–217*).—Post-mortem examination by the New Jersey Experiment Stations of two crows that had been shot on a farm near Stockton, Hunterdon County, N. J., showed the presence of the gizzard worm *Acuaria anthuris*, a common parasite of crows in that section, and of tapeworms in each bird. The examination of blood smears revealed the presence of many microfilariae, thought to be *Diplotriaena tricuspis*, in one of the specimens and in a crow collected later which appeared to be suffering from an injured wing and was kept in the laboratory until it died from tuberculosis.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Indiana Station] (*Indiana Sta. Rpt. 1935, pp. 7–13, figs. 5*).—The progress results are briefly presented of investigations on mechanical control of the corn borer, cornstalk covering equipment, low-pressure pneumatic tires for tractors, combines, and manure spreaders, artificial heat and humidity in poultry housing, field ensilage harvesting equipment, a temporary crib silo, erosion control, hay and grain drying, electric brooding of chicks, precooling of fresh fruits in refrigerator cars, codling moth control with electric insect traps, heating apple-washing solution, soil heating with electricity, and sweetpotato storage.

Surface water supply of the United States, 1934, Parts 1–3, 12A (*U. S. Geol. Survey, Water-Supply Papers 756 (1936), pp. X+383, fig. 1; 757 (1936), pp. VII+216, fig. 1; 758 (1936), pp. X+387, fig. 1; 767 (1936), pp. VI+172, fig. 1*).—These papers present the results of measurements of flow made on streams during the year ended September 30, 1934, No. 756 covering the North Atlantic slope basins, No. 757 the South Atlantic slope and eastern Gulf of Mexico basins, No. 758 the Ohio River Basin, and No. 767 the North Pacific slope basins—Pacific slope basins in Washington and upper Columbia River Basin.

Ground water in south-central Tennessee, C. V. THEIS (*U. S. Geol. Survey, Water-Supply Paper 677 (1936), pp. V+182, pls. 7, figs. 2*).—This report, prepared in cooperation with the Tennessee Division of Geology, describes the ground water resources of an area covering 12 counties in south-central Tennessee.

Potability of water from the standpoint of fluorine content, H. V. SMITH (*Amer. Jour. Pub. Health, 25 (1935), No. 4, pp. 434–441*).—In continuation of the fluorine studies at the Arizona Experiment Station, this investigation made a comparison of the Fairchild, Foster, Willard and Winters, and Sanchis methods for determining fluorine in water. The Fairchild method gave values consistently higher than the other three methods, and the Foster method was not satisfactory when aluminum sulfate had been used to remove fluorine from water. Removal of fluorine from water was found to be impractical by the freezing method, prohibitive in cost by the aluminum sulfate method, and prohibitive in cost by the use of activated carbon after a reduced pH of below

3.0. A concentration of from 0.8 to 0.9 p. p. m. of fluorine in water was found to cause mottled teeth in children during susceptible age. A discussion by J. M. Sanchis is included.

Pump irrigation at the North Platte Experimental Substation, H. E. WEAKLY (*Nebraska Sta. Bul. 301 (1936), pp. 12, figs. 2*).—This bulletin reports the results of work dealing with pump irrigation in the production of crops under conditions approximating general farm practices at the North Platte Experimental Substation. The results from the earlier years of this work have been published previously (E. S. R., 59, p. 678; 68, p. 100).

Cost data for 11 seasons of irrigation pumping are summarized.

Practical aspects of flood control and reclamation of overflowed lands, A. G. CLASSEN (*Tex. State Reclam. Dept. Bul. 27 (1935), pp. VIII+80, figs. 38*).—This is a brief discussion of flood control and reclamation as a source of pertinent information for those interested in the development of flood control and prevention projects on the smaller rivers and streams. The principal part of the discussion treats with the proper design of floodways, channels, and interior drainage of levee improvement districts, and attempts to point out the chief reasons for errors and mistakes most common to this type of public improvement and methods of avoiding them.

Chapters are included on rainfall, run-off, and stream discharge; general plans and methods of flood control; surveys and investigations; the hydraulics and design of floodways and channel improvements; design and construction of levees; and interior drainage, sluice gates, and pumping plants.

A bibliography is included, the contents of which are recommended as reliable references on the subject.

Research in Iowa in soil erosion, soil conservation, and related land use planning, R. E. BUCHANAN (*Iowa Sta., 1936, pp. [2]+47*).—This mimeographed publication outlines the manner of organization and coordination of the research program in soil erosion control, soil conservation, and related land-use planning in Iowa, enumerates the research projects being actively pursued in these subjects, and presents a program of additional research, by projects, considered essential to the success of soil conservation and land-use practices in the State.

Soil erosion in Iowa, R. H. WALKER and P. E. BROWN (*Iowa Sta. Spec. Rpt. 2 (1936), pp. 47, figs. 28, map 1*).—The results of a reconnaissance erosion survey of Iowa is reported, which was conducted in cooperation with the U. S. D. A. Soil Conservation Service. The observations related to factors influencing soil erosion, the extent and seriousness of erosion in the various parts of the State, and control measures which have been found to combat soil erosion successfully.

The survey revealed (1) that only about 13 percent of the total land area of Iowa shows little or no evidence of erosion; (2) that approximately a third of the land shows slight sheet erosion, and up to 25 percent of the original surface soil has been washed away; (3) that more than 14 percent of the land has lost from 25 to 50 percent of its surface soil by erosion, and that most of this area shows occasional to moderate gullying; (4) that about 31 percent of the land has been seriously eroded and from 50 to 75 percent of the original fertile surface soil has been washed away, and that this land has also been moderately to excessively gullied; and (5) that about 9 percent of the land has been severely eroded and has had 75 percent or more of the original surface soil washed away by erosion, and that there has also been moderate to excessive gullying in this area.

Approximately 30 billion tons of soil are estimated to have been washed away from Iowa land since its cultivation was begun by man. This is equivalent to

a loss of more than 137,000 tons of soil per 160-acre farm, or approximately 35 percent of the original surface soil.

Along with the loss of surface soil there has been a tremendous loss of plant nutrients amounting to about 247 tons of nitrogen, 82 tons of phosphorus, and 2,046 tons of potassium for every 160 acres. On the basis of the present price of commercial fertilizers containing these plant nutrients, this loss would amount to approximately $2,975 per acre of farm land. The capital value of Iowa farms is thus being depleted by erosion—a depletion that is actually far greater in value than the land's market price.

Erosion is in the incipient stage on much Iowa land, and the evidences of it are not readily recognized.

Cropping systems in relation to erosion control, M. F. MILLER (*Missouri Sta. Bul. 366 (1936), pp. 36, figs. 18*).—This report has been prepared in cooperation with the U. S. D. A. Soil Conservation Service. It is based on a State-wide survey of the erosion conditions in Missouri, which revealed soil losses much more serious than have generally been recognized. According to this survey one-half of the total area of the State has lost at least one-half of the surface soil and this has taken place in about three generations.

It was found that erosion from cultivated uncropped land totals approximately twice that from land in continuous corn. However, erosion from continuous wheat is only about half, and that from a good rotation is less than 20 percent, of that from continuous corn. The erosion from continuous sod is almost negligible. In general these results are taken to indicate that under ordinary conditions cropping and cultural systems may be so adjusted as largely to control erosion losses.

It is concluded that the standard rotations consisting of 1 or 2 yr. of corn, 1 or 2 yr. of small grain, and 1 or 2 yr. of clover or clover and grass, represent some of the most effective cropping systems known for controlling erosion. The various combinations of small grain crops and Korean lespedeza offer a great deal in the control of soil erosion under Missouri conditions.

When soybeans are sown in rows on rolling land this crop may cause so much erosion as to result in very serious soil losses. In such case the crop should be sown with a grain drill and if possible on the contour. The use of winter cover crops such as barley, rye, or wheat, lespedeza, vetch, and various clovers, is recommended wherever possible in order to lessen erosion losses during the fall, winter, and spring months.

The planting of row and drilled crops on the contour instead of merely with the fence lines offers a great deal for controlling erosion in the case of all soils of rolling topography.

A system of cropping known as strip cropping, which has recently been introduced into Missouri, provides that the crops in a rotation be planted in rather narrow strips, from 50 to 100 ft. wide, across the slope. This is very effective in controlling erosion.

Soil erosion control a basic reconstruction problem (*Puerto Rico Sta. Rpt. 1935, pp. 12, 13, figs. 2*).—This progress report points out that soil erosion has become a very important factor in the agriculture of the island. The heavy compact nature of the soils has resulted in much sheet erosion as well as gullying. The general conclusion is drawn that accelerated erosion of the agricultural land of the island is being brought about largely by using these lands for purposes or in ways to which they are not naturally adapted.

Rainfall, soil erosion, and run-off in South Africa, W. R. THOMPSON (*Univ. Pretoria, ser. 1, No. 29 (1935), pp. 31, figs. 4*).—This report briefly reviews the literature on erosion and run-off control and presents the results of an experiment which has been in operation for 4 yr. The object is to test the

amount of water lost through run-off and the amount of soil eroded from 10 differently treated plats. The selected slope is 3.75 ft. in 100 ft. Each plat is 6 ft. wide and 90 ft. long.

During the course of the experiment the loss of water and soil, respectively, was from 80 to 683 times greater from the uncultivated bare plat as compared with that from the veld intact plat. Avoidance of bare space is therefore fundamental to erosion control. Soil erosion and run-off are concomitant with the growing of cultivated crops. Maize and cowpeas grown for grain bear this out on a 3.75-percent slope. The cultivation of annual hay crops appears to be less detrimental. Teff grass prevents excessive erosion but permits run-off, especially at planting time and during the establishment period. The shallow root system of this crop and the short period it occupies the soil seem to account for the comparatively high run-off. Rhodes grass, representing perennial planted grasses, was most effective in preventing run-off and soil erosion. The establishment of planted grasses on lands subject to erosion is strongly advocated. Burning of surplus material (veld) annually increased bare space and encouraged run-off and soil erosion. The run-off was 27 times greater than that of a veld plat intact during a good rainfall season, 1933–34. This was the most undesirable veld treatment from this aspect.

Although close summer rotative grazing of veld with sheep increased run-off over and above veld left intact, it was less harmful than grazing and burning. It would appear that sympathetic grazing of veld will not increase run-off and soil erosion to a material extent. Overgrazing on the contrary will be decidedly harmful. Unused veld prevented run-off and soil erosion almost entirely on this slope. In two out of four seasons no run-off was recorded, while during the remaining two it was negligible. Fallowing appears to be unsuccessful in preventing run-off and erosion. Kraal manure when applied to maize effected a considerable decrease in run-off. The importance and effect of organic matter in run-off control is indicated. This is now being investigated more fully.

Public Roads, [July 1936] (*U. S. Dept. Agr., Public Roads, 17 (1936), No. 5, pp. [2]+89–112+[2], figs. 16*).—This number of this periodical contains data on the status of the various highway projects receiving Federal funds as of June 30, 1936, and the following articles: A Study of Road Tars, by R. H. Lewis and J. Y. Welborn (pp. 89–109); and Preserve Bench Marks for Future Use, by H. S. Rappleye (p. 110).

A. S. T. M. standards, 1933.—I, Metals. II, Non-metallic materials (*Philadelphia: Amer. Soc. Testing Materials, 1933, pts. 1, pp. XX+1002, pls. 2, figs. 122; 2, pp. XXVII+1298, pls. [6], figs. 203*).—Part 1 contains 185 standards, 104 of which relate specifically to ferrous metals and 70 to nonferrous metals. Part 2 contains 283 standards, of which 60 are standards covering cement, lime, gypsum, concrete, and clay products, 219 relate to miscellaneous materials, such as coal, timber, paints, petroleum, etc., and 4 apply in general to these materials.

1934 and 1935 Supplements to book of A. S. T. M. standards (*Philadelphia: Amer. Soc. Testing Materials, 1934, pp. [7]+216, figs. 24; 1935, pp. [7]+208, figs. 24*).—The first of these supplements contains 49 standards adopted or revised on September 1, 1934. The second contains 36 standards as of September 3, 1935.

Fire resistance of some floor constructions supported by steel beams and theoretical determination of time-temperature curves, R. Schlyter and N. Odemark (*Statens Provningsanst., Stockholm, Meddel. 65 (1935), pp. 51, figs. 27; Eng. abs., pp. 45–51*).—The results of a series of fire tests are reported which were conducted by the Swedish Testing Institute at Stockholm to deter-

mine the fire-resistance capacity of different types of steel beams enclosed partly or wholly in concrete. The specific aims of the tests were to determine (1) whether a steel beam encased in concrete with the lower flange unprotected could be considered a suitable construction from the point of view of fire resistance, (2) whether the demand for insulation of the lower flange with a covering of 4 cm concrete might be considered justified for ordinary fire-resisting buildings, and (3) whether the lower flange of the steel beams unprotected by concrete could possibly be suitably protected by eternit slabs, or by remaining wooden boards covered with reeds and plaster, reeding fixed with extra iron netting, or by a combination of eternit-tretong slab laid on remaining wooden boards covered with reeds and plaster. For the testing of walls the Institute has standardized a method of testing in a vertical furnace.

The results of the test in regard to the temperatures in different layers of the structures, as well as deflections and changes in length, are graphically presented. As to how long the boards with reeding and plaster on the underside of the steel beam structure protect the steel from fire, the test showed that the temperature in the lower flange rose very slowly so long as the plaster and wooden paneling adhered. This was due to the favorable insulating capacity of the wooden paneling. Up to the moment when the wooden paneling was burned away the temperature of the lower flange did not exceed 100° to 150° C. The temperature rose rapidly when the plaster and the insulating panel had burned away. After from 20 to 30 min. the temperature between plaster and wood was 300°, at which time the first crack rose in the plaster, through which the gases generated by the dry distillation of the wood forced their way. Wooden paneling, reeding, and plaster could not be calculated to protect the steel from direct contact with the fire for more than from 40 to 50 min.

A method also is presented whereby the complex mathematical formulas involved in the calculation of the rise in temperature in a wall under test as to its fire-resistant qualities may be solved graphically. It is also shown how the necessary coefficients for the practical use of this method can be determined by a comparison between temperature curves determined in an experimental way at fire tests and theoretical curves determined by graphical calculation.

Oak flooring: Commercial Standard CS56–36 (*Washington: U. S. Dept. Com., Bur. Standards, 1936, pp. II+21, figs. 4*).—This standard provides minimum specifications for commercial grades of white oak and red oak flooring. It covers length, width, thickness, defects, and bundling and the grading tolerances for these requirements.

Minimizing wood shrinkage and swelling, A. J. STAMM and L. A. HANSEN (*Indus. and Engin. Chem., 27 (1935), No. 12, pp. 1480–1484, fig. 1*).—In this report of studies at the U. S. D. A. Forest Products Laboratory it is pointed out that when either green or dry wood is impregnated with a water-insoluble oil, or molten wax, or resin, the impregnating material merely enters the microscopically visible capillary structure. Water in the fine swollen structure of the cell wall can, however, be replaced by a liquid which is completely miscible with water, and this liquid, if also a solvent for waxes and resins, can be replaced by the latter at temperatures above the melting point. This procedure has been used for getting water-insoluble waxes, oils, and resins into the intimate structure of the cell wall using Cellosolve as the intermediate solvent. Only a partial shrinkage of the wood from the green condition occurs, and the subsequent dimension changes with changes in equilibrium relative humidity are materially reduced. The process can thus serve as a combined seasoning and antishrink impregnation treatment for refractory species. Data

obtained by the ordinary impregnation method and data obtained by impregnating dry wood with the waxes and resins dissolved in wood swelling solvents are given for comparison.

Symposium on paint and paint materials (*Philadelphia: Amer. Soc. Testing Materials, 1935, pp.* [5]+*150, fig. 1*).—This symposium includes special articles on preparation, use, and abuse of specifications for paint materials, by P. H. Walker; paint testing, by C. D. Holley; varnish testing, by W. R. Fuller; lacquer testing, by H. E. Eastlack; drying oils, by S. O. Sorensen; zinc pigments, by E. H. Bunce; lead pigments, by R. L. Hallett and C. H. Rose; titanium pigments, by I. D. Hagar; the mineral earth colors and synthetic iron oxides, by J. W. Ayers; chemical colors, by A. F. Brown; natural and synthetic resins, by W. T. Pearce; lacquer solvents and volatile thinners, by R. M. Carter; and turpentine and petroleum distillates as thinners for varnish and paint, by J. M. Schantz.

Cetane rating of Diesel fuels, P. H. SCHWEITZER and T. B. HETZEL (*S. A. E.* [*Soc. Automotive Engin.*] *Jour., 38 (1936), No. 5, Trans., pp. 206–214, figs. 10*).—In the testing method described in this paper, a contribution from Pennsylvania State College, the moment of ignition is determined by a mechanism consisting of a diaphragm in the cylinder head, a phonograph pick-up, a short stiff wire transmitting the motion of the diaphragm to the pick-up, a thyratron relay, and a neon lamp protractor. When ignition occurs in the cylinder the flexing velocity of the diaphragm is sufficiently high so that the voltage generated in the coil of the pick-up trips the thyratron tube and permits a high-tension condenser discharge to be sent through the neon lamp, which by its flashes then indicates the time of ignition.

Because of the absence of friction and arcing the action of the pick-up is more regular than that of a bouncing pin. A similar pick-up is used for indicating injection timing. Using this apparatus and the fixed-ignition-lag method, the Diesel fuel testing in the C. F. R. engine has been so simplified that seven to eight fuels can be tested in an hour with a high degree of reproducibility.

Empirical ratings such as aniline point, Diesel index, viscosity-gravity index, and viscosity-slope index were applied to 19 fuels, and none of them was found to offer a perfect substitute for engine testing. Some can, however, be recommended for approximate rating.

Combustion knock was found to decrease only slightly when the cetane number of the fuel exceeded 55. Cathode-ray oscillograms would indicate that the knock follows the maximum rate of pressure rise more than the ignition lag.

The Purdue plow trash shield, R. H. WILEMAN (*Indiana Sta. Circ. 217 (1936), pp. 4, figs. 4*).—This shield is briefly described and illustrated. It is constructed of sheet metal shaped to form a hood over the top side of the furrow slice as it is turned over. The rear edge of the shield is bent down so that it is perpendicular to the ground surface. This edge is irregular in shape and conforms to the contour of the turning furrow slice. The shield is hinged at the lower front corners and is free to rise and allow any obstruction to pass under it.

Care and maintenance of cotton-gin saws and ribs, C. A. BENNETT and F. L. GERDES (*U. S. Dept. Agr. Circ. 393 (1936), pp. 20, figs. 12*).—Comparisons of the results of ginning tests with gin saws in good and in poor condition showed an average difference in the monetary value of the lint of more than $2 per bale with cotton 1⅛ in. and longer and of about $1 per bale with cotton shorter than 1⅛-in. staple length.

The greatest factor in raising the value of the bale was the greater lint turnout with the good saws. The saws in good condition ginned the seed closer than

the worn saws, resulting in an average difference for all cottons and conditions employed in this study of about 10 lb. of lint per 1,500 lb. of seed cotton. The second factor was the enhancement in grade. Increase in staple length was of only minor importance.

Using saws in poor condition as compared to the saws in good condition increased the time of ginning about 30 percent with the longer and about 20 percent with the shorter staple cottons. Although the power requirement was slightly less with worn saws, the energy consumption was equal or greater because of the added ginning time.

Sharpening procedure with some machines comprises only a 2-stage gumming and side dressing; while with others it is a 3-stage gumming, side-dressing, and filing or sand-box operation. For hand-picked short-staple cottons and for all roughly harvested cottons the 2-stage method is usually sufficient, but the 3-stage method is to be recommended for hand-picked long-staple cottons.

Gin saws handling roughly harvested cotton require more frequent sharpening than those handling clean-picked cotton, and increase in percentage of damp or wet cotton for either method of harvesting increases the damage to the saw teeth and the frequency with which they must be reconditioned.

The best method of keeping gin saws in proper condition and protecting them from rust during the idle season is to cover them wtih a coat of suitable oil, which can be easily removed at the beginning of the next ginning season.

Gin ribs require periodic attention in order to preserve the essential relations with the saws that contribute to smooth and satisfactory ginning. The saws should revolve in a central position between each pair of ribs, or with a space equal to a saw thickness on each side, to prevent dragging of the teeth against the ribs and the consequent adverse effects on both cotton and saws.

Worn ribs may be replaced by new ones or repaired by various methods. These repairs consist of welding new materials upon the worn spots to build up the ribs, followed by grinding to correct dimension and shape; or covering the worn surfaces with hardened plates of suitable width and minimum thickness to once more give well-defined edges to the ribs. A smooth polish on the ribs contributes to good ginning and can be preserved from season to season by coating with oil.

Farm buildings, J. C. WOOLEY (*Columbia, Mo.: Univ. Coop. Store, 1936, pp. [6]+266, figs. 221*).—This is a compilation of information on farm structures, presented with the idea of reviewing the underlying science involved and finding its application to the conditions imposed by the different structures. It is divided into chapters on the development of farm buildings in America; the function of buildings in the business of farming; heat—its production, measurement, and transfer; heat transfer through separating mediums; heat relationship in farm buildings; moisture in farm buildings; the comfort zone; ventilation systems; mechanics of farm buildings; design of structural members; barn frames; gable—combination and shed rafters; gambrel, gothic, and hip rafters; wood as a building material; concrete; brick blocks and steel; cobblestone, rammed earth, and log construction; siding, roof covering, and insulating material; location and planning the farmstead; machinery storage and repair buildings; planning buildings for the dairy enterprise; dairy barns and milk houses; silos; buildings for the poultry enterprise; buildings for the hog enterprise; beef cattle and sheep barns; horse barns and general-purpose barns; grain and hay storage buildings; storage structures for fruit and vegetables; the farm home; heating the farm home; water systems; disposal of waste from the home; remodeling, care, and repair of buildings; cost of new and appraisal of old buildings; fencing the farm; and drafting and interpretation of plans.

The disposal of wastes from milk products plants, E. F. ELDRIDGE (*Michigan Sta. Spec. Bul. 272 (1936), pp. 18, figs. 7*).—Technical information is presented on the elimination of loss of milk solids within the factory and the safe treatment of solids which cannot be economically saved.

It is pointed out that a large share of the milk solids in the wastes of many factories comes from the can washer. Usually about 1 lb. of milk is lost for every 9 cans washed, and some plants wash as many as 2,000 cans daily. These solids are discharged over a 3- to 4-hr. period and would require a stream having a minimum flow of about 55 cu. ft. per second for satisfactory dilution.

Every washer should be provided with a drip collector, as one-half of the milk lost through the can washer may be prevented by collecting the drip. Of the remainder, 80 percent may be saved by collecting a short cold water rinse of the cans, but the disposal of this rinse may be difficult and its collection may or may not be practical. In some cases, however, its elimination from the wastes may avoid the cost of building treatment units, and in such cases it could be mixed with the drippings and sold or given to the producer for feeding purposes.

The drainage from storage tanks, coolers, churns, vats, and other equipment should be collected in cans and either returned to the product or used for feeding purposes. A cold water rinse of these units may also be collected and used.

Skim milk, buttermilk, and spoiled milk should be considered byproducts and should never be discharged into the factory sewers. These byproducts are highly concentrated, and treatment processes for wastes including them are costly.

Whey and cheese washings are also concentrated, and wherever possible should be used either for the manufacture of other products or for feeding. A limited amount of whey and washings may be treated. Considerable effort should be spent in finding an outlet for the whey and as much of the first washings as is possible. These efforts will be amply repaid by the savings in the cost of the treatment required for the factory wastes.

It has been found that the septic process cannot be successfully applied to milk waste, since products are formed by the septic fermentation of milk solids that are much more detrimental to the stream than are the fresh solids.

In the case of small plants located on farms or in sparsely populated districts, irrigation may be used as a means of waste disposal. This method consists of pumping or otherwise spreading the waste onto several acres of land that are kept under constant cultivation. Provision must be made to apply the waste to various portions of the field on alternate days so as to allow the waste to seep into the soil before a second application is made. Sandy soil is best adapted for this practice. Should odors become obnoxious, chloride of lime, sodium hypochlorite, or liquid chlorine may be applied to the waste before it is pumped to the field. Usually the method is used only during the summer months when stream flows are low.

A detailed discussion is presented of the design, construction, and operation of a biological filter for milk waste disposal. This method of disposal consists of the intermittent application of the waste to a filter composed of gravel or crushed stone. The treatment plant necessary for the biological filtration of milk waste consists of three units. These are (1) a holding tank to equalize the waste and to give a longer operating period for the filter, (2) the filter, and (3) a settling tank to remove the suspended material from the waste discharged by the filter.

Directions are given for a method of making the 5-day biological oxygen demand determination, which is considered the essential test to determine the strength of the wastes and the efficiency of the filter.

AGRICULTURAL ECONOMICS

Agricultural economic facts basebook of Iowa, L. K. Soth (*Iowa Sta. Spec. Rpt. 1 (1936), pp. 179, figs. 192*).—"The purpose of this basebook is to make available to farmers, as well as to students of agricultural affairs, economic facts and figures which pertain to the agriculture of Iowa. The statistics and analyses which make up this book deal with and describe chiefly those economic forces which are outside of the province of any individual farm." It was prepared by the rural social science and economics section of the station and the extension service of the Iowa State College of Agriculture and Mechanic Arts. The eight chapters include data on the following and related subjects:

Iowa farm income.—Included are 11 tables and 8 charts and maps on farm value and gross and cash income from different farm products, farm expenditures, monthly receipts of income, farm income of Iowa counties, monthly indexes of income of industrial workers and of cash income from sale of farm products in the United States, etc.

Iowa farm prices.—The 11 tables and 15 charts show, for periods of years, the monthly prices and index numbers of prices paid Iowa farmers for different products and indexes of farm product prices in the United States, corn-hog ratios in Iowa and at Chicago, purchasing power of Iowa hogs and corn, and prices paid by farmers for different commodities in Iowa and in the United States.

Iowa farm production.—The 39 tables and 85 charts and maps included present data on the numbers and value of different kinds of livestock on Iowa farms; monthly marketings total and to stockyards and packing houses of hogs, cattle, and sheep; production of creamery butter and shipments of butter, dressed poultry, and eggs to New York, Philadelphia, Chicago, and Boston; the acreages, yield, and value of leading crops, 1880–1934, for the State by years and by counties for 1932 and 1933; and acreages of crops in the United States, by States, and the production, 1933–34, by countries of the world.

Iowa farm real estate.—The 29 tables and 19 charts and maps include data as to land values; acreages operated by owners, part owners, managers, and tenants; cash rents; use of lands; lands owned by corporations; amount, sources, and purposes of farm loans; mortgage foreclosures; deficiency judgments; etc.

Iowa farm taxes.—Sixteen tables and 9 charts and maps present data as to taxes per acre, tax paying power of Iowa farm products, income and expenditures of Iowa administrative units, tax delinquency, etc.

Types of farming in Iowa.—The 3 tables and 28 maps in this chapter show the soil types, extent and seriousness of soil erosion, rainfall, temperatures, size of farms, use of lands, acreages and yields of different crops, feed units per acre produced, animal units per acre, milk production, etc., in the different type-of-farming areas of the State.

Iowa farm home conveniences.—The 15 tables and 13 charts and maps present data as to ownership, value, construction, age, condition, number of rooms, etc., of houses, number of conveniences of different types, etc.

Iowa population.—The 8 tables and 15 maps and charts present data as to distribution, constituency, changes in, etc., of the population of the State.

Current Farm Economics, Oklahoma, [August 1936] (*Oklahoma Sta., Cur. Farm Econ., 9 (1936), No. 4, pp. 81–101, figs. 3*).—Included, besides the usual tables showing price indexes in the United States and Oklahoma and of purchasing power of Oklahoma farm products, are articles on the general economic situation and the agricultural situation in Oklahoma, by T. R. Hedges;

Social Aspects of Rural Shifts of Farm Population in Oklahoma, by O. D. Duncan (pp. 88–93); Some Factors Associated With Profitableness of Northwestern Oklahoma Farms During 1935, by E. D. Hunter (pp. 94–96); and Oklahoma has Radically Changed Its Tax Machinery the Past Five Years, by J. T. Sanders (pp. 97–99).

Methods employed by geographers in regional surveys, G. D. HUDSON (*Econ. Geogr., 12 (1936), No. 1, pp. 98–104, figs. 5*).—Some of the more recent methods for gathering and recording data and portraying distributions are described.

Readjusting Montana's agriculture, VII, VIII (*Montana Sta. Buls. 318 (1936), pp. 19, figs. 6; 319, pp. 27, figs. 13*).—These bulletins continue the series previously noted (E. S. R., 75, p. 250).

VII. *Montana's dry-land agriculture,* E. A. Starch.—Information is presented as to crop acreages, yields, and production; the relationship between wheat yields, grades of farm lands, and the economic limits of the lower grades of lands for farming purposes; present farm enterprises; farm practices and size of dry-land farms; the possibility of economic readjustments; and the adjustments needed to afford adequate farm income.

VIII. *Tax delinquency and mortgage foreclosures,* R. R. Renne.—Data are presented regarding the extent of, increases in, and causes of farm tax delinquencies and farm mortgages and foreclosures. Measures for reducing tax delinquency and farm debt adjustment are discussed.

An analysis of the present status of agriculture on the Sun River irrigation project, P. L. SLAGSVOLD (*Montana Sta. Bul. 321 (1936), pp. 60, figs. 15*).—This analysis is based on annual farm census and other reports for the project, data furnished by farmers, the soil survey previously noted (E. S. R., 60, p. 116), climatological data in U. S. D. A. Weather Bureau publications, and tax data obtained from county officials and reports of the Montana State Board of Equalization.

The development and present status of the project, the climate, soil, topography, water supply, irrigation, drainage, transportation facilities, markets, and operation and maintenance charges of and the tax levies on the project are discussed. Data are included and discussed on acreages and yields of crops, numbers of different kinds of livestock, acreages irrigated, tenure of farm operators, crop and livestock combinations, etc. Budgets for 80-, 100-, 120-, and 160-acre farms showing livestock inventories and feed requirements, cropping programs, yields, and costs, and farm income and farm expenses by items are presented to test the relation of size of farm and net income.

An economic study of land utilization in Broome County, New York, T. E. LAMONT ([*New York*] *Cornell Sta. Bul. 642 (1936), pp. 51, figs. 16, map 1*).—This bulletin is the fourth in the series previously noted (E. S. R., 75, p. 270).

"About 27 percent of the county is in land class I, and 23 percent in land class II. Most of land class I is idle or in woods, and is primarily adapted to forestry and recreational uses. A large amount of land class II is idle or in woods, but on a considerable part farming is still being carried on. It is better suited to forestry and recreational uses than to agriculture.

"Land in classes III and IV is land that is adapted to permanent agriculture; about 44 percent of Broome County is in these land classes. The higher the land class, the more intensively the land is used.

"Most of the soils in land classes I and II are poorly drained upland soils; in land class IV, about 60 percent are well-drained valley soils.

"In land classes I and II, a large proportion of the houses standing 30 yr. ago are gone, falling, or vacant; of the operated farms, more than three-

quarters were classed as poor. In land class IV, most of the farms were classified as good or excellent.

"The full assessed value of land class I was $12.11 per acre, and in land class II, $18.47. The higher the land class, the higher the full value; land class IV averaged about $47 per acre.

"Practically all farms that will remain in agriculture permanently should be served by hard roads, electric lines, and other modern services. In land classes III and IV, about 54 percent of the farms were on dirt or gravel roads, and 57 percent did not have electric service available in 1933. Suggested road and electric programs have been prepared so that practically all the farms in these land classes . . . will be served by hard roads and electric lines."

An economic study of land utilization in Tioga County, New York, P. B. JONES ([*New York*] *Cornell Sta. Bul. 648 (1936), pp. 40, figs. 16, map 1*).—This bulletin is the fifth in the series noted above. About 68 percent of the county is in land classes I and II, and about 30 percent in land classes III to V.

"In land classes I and II, a large proportion of the houses standing about 30 yr. before were gone, falling, or vacant, and of the occupied farms, 83 percent or more were classed as poor or fair to poor. In land classes III to V, a large proportion were classed as good to excellent. Also, in the higher land classes there were more buildings per square mile.

"The assessed full value per acre of land class I was $10.35, and land class II $15.04. The higher the land class the higher the value; land class V averaged about $60 per acre. Farms located wholly in land classes I and II made up 51 percent of the county area, but only 7 percent of the total full value. About 23 percent of the tax base was represented by all classified land, 26 percent by public utilities properties, and 51 percent by residential and industrial properties. A large proportion of the public utilities were railroads. . . .

"In land classes III to V, about 31 percent of the farms were on dirt or gravel roads and 58 percent did not have electric service available in 1934. Suggested road and electric programs have been prepared."

Montana land ownership: An analysis of the ownership pattern and its significance in land use planning, R. R. RENNE (*Montana Sta. Bul. 322 (1936), pp. 58, figs. 16*).—This is an expansion of Bulletin 310 (E. S. R., 75, p. 270), including additional details and discussing more completely the social and economic implications.

Of the total area of the State, approximately 44 percent was owned by public agencies in 1934 (Federal Government 35.6, State 5.7, and counties 2.7), 14 percent by corporations, 30.8 percent by private individuals resident in the State, and 10.9 percent by nonresidents of the State.

Tax delinquency and mortgage foreclosures were the principal immediate causes of changes in ownership. The fundamental causes were overspeculation in land, overdevelopment in local government, and improper utilization of land. Considerable progress has been made in establishing a planned use of lands through (1) consolidation of farms by more successful farmers taking over abandoned lands, (2) formation of cooperative grazing districts, (3) control of public ranges through the Taylor Grazing Act, and (4) blocking lands into economic units through purchase of selected areas by the Federal Government.

Inventory of land use in Tennessee.—A preliminary report, C. E. ALLRED, S. W. ATKINS, W. P. COTTON, and J. E. MASON ([*Nashville*]: *Tenn. Welfare Comm., 1936, Rpt. 5, pp.* [*1*]+*38, figs. 22*).—According to this report, in which the Tennessee Experiment Station cooperated, in Tennessee 49.6 percent of the

total land area is woodland. Cropland occupies 28.7 percent, pasture land (exclusive of woodland pasture) 13.6, farmsteads and farm roads 4.8, public roads and railroads 1.5, towns and cities 0.5, lands of little or no use 0.3, and miscellaneous 0.9 percent.

Regional grouping of crop production in Tennessee.—A preliminary report, C. E. ALLRED, W. E. HENDRIX, and B. H. LUEBKE ([*Nashville*]: *Tenn. Works Prog. Admin., 1936, Rpt. 12, pp. III+38, figs. 23*).—The principal areas have been classified into three groups—group 1, those areas which, in general, rank highest in agricultural productiveness; group 2, those which are intermediate; and group 3, those which rank lowest.

The percentage of total land area in crops, pasture, and woodland is determined to a great extent by the productiveness of the region. Cropland, which constitutes the most intensive of the three major land classes, comprises 41.4 percent of the total land area in group 1, 32.3 percent in group 2, and 17.2 percent in group 3. The percentage of total land area in pasture is high (19.8) on group 1 land and low (6) on group 3 land, and is highest in areas having a large acreage of fertile land which is interspersed with and adjacent to uncultivatable or poor land. All-hay crops comprise 24 percent of the cropland harvested in group 1, 21.9 percent in group 2, and 19.8 percent in group 3. Alfalfa and timothy are grown principally on the group 1 soils and wild grasses on group 3 soils.

Farm tenancy in Tennessee, C. E. ALLRED, W. E. HENDRIX, and B. D. RASKOPF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Rpt. 17 (1936), pp. III+31, figs. 16*).—In May 1935, the relative relief burden was greater among farm tenants than among farm owners. Farm owners free of debt and operating farms large enough to constitute economic units of operation generally were not dependent on relief funds. Farm tenant families of both the general population and the relief population were larger than owner families, and relief families were larger than nonrelief families.

The standard of living of farm tenants of the general population was considerably lower than that of owners. Though higher for owners than for tenants, the differences in living standards were not so great among negroes. Low educational attainment is characteristic of farm tenants compared with farm owners. In 1930, 37.4 percent of all farm tenants and 43.9 percent of cropper tenants had changed farms within the past year, compared with 6.2 percent of farm owners.

Farm tenants of both the general and the relief population were younger than farm owners. The relief rate in general was less among negro farmers than among white farmers.

Cropper tenants constituted 44.3 percent of all tenants in the State, and were found mainly in the cash-crop production areas, and were a heavier relief burden than other types of tenants. Croppers constituted 61 percent of the negro tenants and 39 percent of the white tenants.

Almost one-half (46.2 percent) of all farms in Tennessee were operated by tenants in 1930. The greatest concentration of farm tenants was in the extensive cotton growing counties of west Tennessee and in the dark fire-cured tobacco growing area of the Northern Highland Rim. Among negro farmers the percentage of tenancy was considerably higher than among white farmers, 77 and 44, respectively. About 34 percent of all farm tenants in Tennessee were cash tenants in 1880. This percentage declined to 10 in 1925 and increased to 10.8 in 1930.

Farm tenants (other than cash and cropper) constituted 44.9 percent of all tenants of the State. They are found mainly in the counties of the Western

Highland Rim, eastern part of west Tennessee, and North Eastern Highland Rim.

Inequalities arising from the assessment of farm real estate in South Dakota, R. B. WESTBROOK and N. V. STRAND (*South Dakota Sta. Bul. 300 (1936), pp. 39, figs. 6*).—Data were obtained as to the sale price of 1,758 bona fide transfers of farm real estate during the period 1925–34 in 20 counties and as to the assessed valuations of the properties of the date nearest the time of the sale. These data are analyzed on a State-wide basis and by counties. Tables and charts show on a State-wide basis the average levels of assessment, average deviations, and coefficients of dispersion for the properties grouped on the basis of percentage of average farm value and of average acre value. Other tables show similar data by counties for the farms grouped on the basis of sale value. Defects in the present system of making assessment are discussed, and suggestions made for an improved system.

Of the 1,758 farms, 13 percent were assessed at from 10 to 60 percent of their sale value, 40 percent at from 60 to 100, 38 percent at from 100 to 200, and 9 percent at from 200 to 350 percent. Low value farms tended to be overassessed, and high value farms to be underassessed. Levels of assessments varied appreciably among the counties. The better and older farming areas were found to be less subject to variations in assessments than were the sections in which land values were not so well established.

Farm taxation (*Rhode Island Sta. Rpt. [1935], pp. 4, 5*).—Additional data (E. S. R., 73, p. 703) are reported on real estate taxes in Rhode Island.

Comparative ability of Tennessee counties to finance their governmental functions.—A preliminary report, C. E. ALLRED, S. W. ATKINS, J. H. MARSHALL, W. E. COLLINS, and C. A. TOSCH ([*Nashville*]: *Tenn. Welfare Comm., 1936, Rpt. 9, pp. [III]+44, figs. 17*).—The purpose of this preliminary study, in which the Tennessee Experiment Station cooperated, is to ascertain the relative ability of Tennessee counties to finance their governmental functions. This ability is estimated on both a county total and a per capita basis. Slightly more than one-fourth of the total financial capacity of the State is in four counties and one-third is in seven counties. The principal causes of these differences are natural resources, such as soil and topography, size of counties, and the extent of urban development. Among other important factors are public debt, tax levy, and the need for additional expenditures for highways and school buildings.

[Investigations in farm management by the Indiana Station, 1934–35] (*Indiana Sta. Rpt. 1935, pp. 37–40, fig. 1*).—Brief summarizations are included of the findings not previously noted in studies of (1) costs of producing potatoes, tomatoes, and onions in northern Indiana; (2) farm buildings on 144 farms in Benton and Whitley Counties; (3) the influence of farm practices on incomes on 40 central Indiana farms; (4) the value of farm machinery and minor equipment in 1934 on 370 farms in 4 type-of-farming areas of the State; (5) combine harvester thresher costs in 1934 of 27 cooperators; (6) labor, power, and machinery costs on 425 farms in 1933; (7) real estate prices and transfers in 1933 in 4 central Indiana counties; and (8) the effects of soil type and pasture practices in Monroe and Lawrence Counties.

Part-time farming in Indiana, F. V. SMITH and O. G. LLOYD (*Indiana Sta. Bul. 410 (1936), pp. 28, figs. 6*).—"The objectives in this study were (1) to recognize the extent and geographical location of part-time farming in Indiana, (2) to appraise the social and economic characteristics of typical part-time farm families, (3) to determine the net effect of the farm enterprises on the economic condition of part-time farm families, and (4) to obtain facts indicat-

ing the types of situations to which part-time farming is adapted and the types of farm enterprises which are most effective."

Records for the calendar year 1933 were obtained for 1,508 farms in three areas—industrial, limestone, and coal mining—of the State. Of the farms, 428 were less than 3 acres in size; 416, 3 and less than 10 acres; and 664, 10 and less than 51 acres in size. Of the farms 1,193 were owner-operated and 315 tenant-operated. Tables show by size-of-farm groups the average size and utilization of lands; date of purchase, average purchase price, 1933 value, of dwellings and of land, mortgage indebtedness, etc., of owner-operated farms; amount of indebtedness of owners and tenants; numbers of horses, hogs, cows, and hens; acreages in gardens and crops; facilities—kind of road, household conveniences, and automobiles; cash income from farm products sold, occupation away from the farm, and from other sources; value of farm products of different kinds produced and sold; farm expenses of different kinds; etc. Data as to size of family, age of the head of the family, kind and condition of the houses, school attendance, standard of living, occupations other than farming, taxation delinquency, etc., are presented in the text.

The farms averaged 13.09 acres, of which approximately ⅔ acre was in vegetable crops, 4 acres in harvested crops, and 8½ acres in pasture, woods, farmstead, idle, waste, etc. Of 1,193 owner-operated farms, 588 were purchased from 1919 to 1928 and 338 from 1929 to 1933. Of the 1,508 farms, 99 percent had gardens, 87 poultry, 67 at least 1 cow, 42 hogs, and 28 percent horses. Approximately 54 percent of the part-time farmers were employed in industry, 15 percent had a business of their own, and 30 percent were engaged in nonagricultural occupations. An average of $201 worth of farm products was produced per farm. The average income earned away from the farm was $487. Approximately 31 percent of the real income of the family came from the farm. The average net income was $97 for owner-operators and $70 for tenants. The average total living cost per family was $436. The average cost of food purchased, $198, was approximately equal to the value of products produced.

Other findings were that part-time farming tends to develop on both submarginal and good agricultural lands. The number per square mile and the size of and volume of agricultural enterprises on part-time farms are greater in Indiana in areas of greatest urban and industrial development. The average value of dwellings on the farms studied was greater than the value of land and other buildings, indicating that the part-time farm is primarily a home rather than a business. The part-time farms surveyed were rather advantageously located as regards good roads, schools, trading centers, and places of nonagricultural employment. The more-than-10-acre group of farms had the highest net income. The standard of living maintained by the part-time farm families indicates that in most instances such families are not an undesirable element in the commmunity. Part-time farmers have increased the taxable wealth of many communities. Part-time farming affords a certain economic stability for the wage earner, and in many instances enables him to provide better food and living conditions for his family. Under present conditions, part-time farmers do not seriously compete with full-time farmers. The average part-time farmer should have a reasonable assurance of at least 120 days per year of gainful employment away from the farm or a farm business large enough so that the sale of products is a major source of cash income.

The economics of bean production in Michigan, K. T. WRIGHT (*Michigan Sta. Spec. Bul. 270 (1936), pp. 46, figs. 14*).—This bulletin gives general information regarding the bean industry, including world, United States, and Michigan production, the acreages, yields, and prices by States, and monthly prices in

Michigan, and analyzes the data regarding costs and returns in bean production in Michigan obtained from 166 farm records for 1929, 97 for 1930, 103 for 1931, and 65 for 1932. Tables for each year and for the periods show for all the farms, for those on Brookston, Miami, and sandy soils, and for those growing red kidney beans, by items, the average growing, harvesting, and overhead costs and returns per acre, the profits and losses per acre, and the labor and power requirements. Other tables show for pea beans on all farms the effects on costs and returns of different factors—yield, dates of plowing and planting, drainage and value of land, variety of beans raised, use of green and barnyard manure and commercial fertilizer, acreage of beans per farm, efficiency in use of labor, power, and machinery, and the cumulative effects of good growing practices.

The average costs per acre of producing pea beans were 1929, $36.17; 1930, $28.41; 1931, $24.60; and 1932, $20.40. The average returns were $11.41, $22.26, $16.01, and $14.34. The average yields per acre were 12.1, 9.4, 14.1, and 22.1 bu., averaging 13.2 bu. for the period. The returns per hour of labor were 20 ct. Of the average total costs labor, power, and machinery made up 43 percent, land use 22, manure and fertilizer 15, seed 10, and threshing and other costs 10 percent. The returns per hour of labor averaged 29 ct. on the Brookston soils, 9 ct. on the Miami soils, and —9 ct. on the sandy soils. The returns for red kidney beans averaged 23 ct.

The author concludes that in the immediate future the total production cost will probably be 15 percent lower than the 1929–32 average, that bean prices will probably not average higher than the average for the 4 yr.—$3.38—and that the possibility of profits from beans is very limited when the yield is not greater than the 10-yr. State average of 10.7 bu. He adds that "growers using good practices and efficient methods and obtaining good yield can reasonably hope for a fair management return."

Cotton production in Mexico, P. K. Norris (*U. S. Dept. Agr., Bur. Agr. Econ., Foreign Agr. Serv., 1935, F. S. 65, pp. 15, fig. 1*).—Statistics covering a number of years on the acreage, production, and yields of cotton are included. The factors affecting the production and different cotton-growing districts are described, and the outlook for increased production is discussed.

Quality of lettuce as it affects the New York lettuce industry, J. E. Knott ([*New York*] *Cornell Sta. Bul. 651 (1936), pp. 17, figs. 9*).—Yearly carload shipments of lettuce originating in New York decreased from an average of 3,447 cars for the period 1927–29 to 1,555 cars for the period 1932–34, while those from western States decreased from 44,900 to 42,332 cars. This bulletin reports results of the study made to determine some of the factors that might be related to the decline in lettuce production in New York. It is based chiefly on data for the period 1927–35 obtained from 15 selected growers at Elba and Oswego who were careful of the quality of their pack and 15 growers who were inclined to be careless in packing. Some data were also used from a quality price study including 40 growers at Fulton in 1932, and one made by O. W. Terry in 1935 including 28 growers in Oswego County. The practice of distributing shipments in different cars with a view to avoiding a low return for poor quality is discussed.

Poor packers on an average receive a lower price for their lettuce than did good packers each year 1927–35, the differential being 15 ct. or more in 4 of the 9 yr. In only 24 of the 96 weeks in the 9 shipping seasons did 50 percent of the shipments of poor packers bring more than the average weekly price, while over 50 percent of the shipments of good packers brought more than the average weekly price in 75 of the 96 weeks.

Methods of securing better packing are discussed. The author concludes that "more important than this packing of two grades, however, is the necessity for allowing the lettuce to reach the proper degree of maturity before it is cut, and the elimination from the market of all lettuce that is loosely headed. Unless definite measures are taken by growers consistently to ship a high-quality pack and so to develop and maintain a good reputation for New York State lettuce, this industry in New York State cannot possibly be restored to its proper place in consumer markets."

1935 onion costs of production in Michigan, K. T. WRIGHT (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 238–240*).—Records were obtained from 40 growers. Analysis is made of the different items of cost and comparisons made with the findings in a similar study in 1934. Comparison was also made between the costs on the 10 low-cost and the 10 high-cost farms in 1935.

Costs of producing and marketing sugar beets in Michigan in 1935, K. T. WRIGHT (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 235–238*).—Records were obtained from 95 farmers. Analysis is made of the yields per acre, amounts and cost of contract labor, and marketing costs. Comparisons are made with a similar study in 1934.

Economic studies of dairy farming in New York.—XII, 150 farms in the Tully-Homer area, crop year 1931, J. R. RAEBURN ([*New York*] *Cornell Sta. Bul. 644 (1936), pp. 53, figs. 16*).—This bulletin is the third in the series previously noted (E. S. R., 69, p. 454). The study is based on records for the year ended March 31, 1932, obtained from 101 farms producing grade A milk and 49 farms producing grade B milk. Price and weather conditions, amounts of farm capital, receipts, expenses, etc., on the types of farms are discussed. An analysis is made of the factors affecting labor income and the costs and returns in milk production. Comparisons are made with the findings in the previous studies.

The average labor income of the operators was $390 on the grade-A-milk farms and −$130 on the grade-B-milk farms. A 10-percent-of-average increase in the number of cows or in labor employed was accompanied on the grade A farms by an increase of about $60 in the labor income, but on the grade B farms a 10-percent-of-average increase in the number of cows had no effect on labor income and a similar increase in labor reduced the labor income $51. On the grade A farms an average of 40 tons of milk was produced per man employed and 6,884 lb. per cow, as compared with 34 tons and 6,717 lb., respectively, on the grade B farms. An increase of 10 percent of average in the number of animal units per man, the milk yield per cow, and the resultant of these two—the rate of milk production per man—increased the labor income more than $140 on grade A farms and more than $50 on grade B farms. The acreage of crops per man, cash-crop yields, and cattle increase per cattle unit had little relation to labor income. Such incomes were high where feed-crop yields were high. Satisfactory labor incomes were obtained only where the value of all farm labor was less than 30 percent of the total receipts and where grade A premiums were obtained.

"The average net cost per hundredweight of milk sold was $2.17 for grade A milk and $2.14 for grade B milk. The average price received was $1.95 per hundredweight for grade A and $1.71 for grade B. The return per hour of labor was 22.4 ct. in grade-A-milk production and 12.6 ct. in grade-B-milk production. Total feed costs made up about 42 percent and total labor costs about 30 percent of the cost of both grade A and grade B milk. In herds of less than 16 cows, the net cost of grade A milk was $2.49 and of grade B milk $2.75 per 100 lb. In herds of 26 or more cows, the net cost was $2.13

for grade A milk and $1.91 for grade B milk per 100 lb. Net cost of production decreased from $2.33 to $1.99 per 100 lb. in grade A herds and from $2.52 to $1.94 per 100 lb. in grade B herds as milk yields increased from less than 6,500 lb. to 7,500 lb. and more. Labor efficiency in milk production, as measured by tons of milk produced per man, was an important determinant of cost of production. The net cost per 100 lb of milk sold decreased from $2.41 to $2.01 for grade A milk and from $2.51 to $1.76 for grade B milk as tons of milk per man increased from less than 35 to 45 or more. Returns per hour of labor increased from 12 ct. to 36 ct. with grade A milk and from 2 ct. to 24 ct. with grade B milk. Net production costs per 100 lb. for grade A milk decreased from $2.41 to $2.11 and net returns increased from $1.92 to $2.01 as the proportion of the total milk sold that was sold from September to December increased from 27 percent to 38 percent."

Studies in Vermont dairy farming.—IX, The Champlain Valley during a major depression, J. A. HITCHCOCK and S. W. WILLIAMS (*Vermont Sta. Bul. 405 (1936), pp. 24. figs. 2*).—This bulletin continues the series previously noted (E. S. R., 72, p. 123). The study, which deals with the dairy farm management conditions during the year ended March 31, 1933, is based on data regarding 448 herds. The physical and agricultural characteristics of the area are described. An analysis is made of the effects of production per cow, labor efficiency, size of farm, and type of market upon the profitableness of the farm business.

The average receipts per farm were $1,856 and the average expenses $1,752, resulting in a labor income of —$466 if 5 percent interest is allowed on the capital investment. The labor income increased from —$674 for herds averaging less than 160 lb. of butterfat per cow to —$188 for herds averaging 250 lb. or more of butterfat per cow. The hours of labor, cost of feed, miscellaneous costs, and total cost per cow increased as production of butterfat per cow increased, but the cost per pound of butterfat decreased. The average labor incomes with different numbers of work units per man were: Less than 190 units —$482, 190–249 —$457, 250–309 —$563, 310–369 —$366, and 370 units and over —$433. The average labor income was —$186 for the farms selling their milk in a grade A market during the entire year, —$475 for those selling in such a market only during part of the year, and —$531 for those selling in a grade B market only. The average labor income decreased $17 for each additional cow, being —$818 for the farms with less than 14 cows and —$950 for those with 38 or more cows.

Milk-distribution costs in West Virginia.—II, A study of the costs incurred by 75 producer-distributors in the Clarksburg, Fairmont, Morgantown, and Wheeling markets for a twelve-month period during 1934–1935, W. W. ARMENTROUT and R. O. STELZER (*West Virginia Sta. Bul. 270 (1936), pp. 32*).—Records were obtained from 17 producer-distributors in the Clarkburg market, 24 in the Fairmont market, and 14 in the Morgantown market for the year ended March 31, 1935, and from 20 such distributors in the Wheeling market for the year ended May 31, 1935, and comparisons made with 9 milk-distributing plants in the 4 cities and of 22 plants in the State studied in 1933 (E. S. R., 73, p. 865).

The costs of distribution for the individual producer-distributors ranged from $1.06 to $3.39 per 100 lb. of milk-equivalent, averaging $1.763. Of the costs, 22.1 percent were plant costs, 68.1 delivery costs, 5.6 administration, and 4.2 percent interest. The average cost for labor was 88.7 ct., for depreciation 16, building and equipment costs 21.5, truck operation 30.3, bad accounts 9.1, interest 7.4, and other costs 3.3 ct. The average labor efficiency—number of pounds

of milk-equivalent sold per hour of labor—was 28. The total cost per 100 lb. of milk sold was $1.49 for the producer-distributors selling 35 lb. or more of milk per hour of labor, $1.79 for those selling 21 to 34 lb., and $2.38 for those selling less than 21 lb. Truck costs averaged 41.1 ct. per 100 lb. of milk, varying from 33 ct., where the producer-distributor had sufficient volume of milk to haul large loads, to 58 ct., in the case of producer-distributors having only sufficient milk for small loads. The total cost per 100 lb. of milk was $1.60 for the producer-distributors selling over 150,000 lb. per year, $1.79 for those selling 70,000 to 149,000 lb., and $2.33 for those selling less than 70,000 lb.

The average cost of distribution of the 9 distributing plants in the cities studied was $1.92 per 100 lb. of milk as compared with $1.76 for the 75 producer-distributors. The higher cost for the distributing plants was due largely to a higher wage rate, cost of pasteurization, a higher investment per 100 lb. of milk sold, the purchase of surplus milk, and the cost of special deliveries made to customers.

Agriculture's share in the national income (*U. S. Dept. Agr., Agr. Adjust. Admin., 1935, pp. II+37, figs. 21*).—"The charts and tables in this pamphlet have been assembled to present, in more or less consecutive form, material on the national income at various periods in the national life and the contribution made to that total by agriculture; the gross income of the farmers of the country; their cash income; the income available to them after meeting their production costs; the purchasing power of these different types of income; and the interrelation between the income and purchasing power of farm and city in the national economy."

Indexes of prices received by Washington farmers, C. C. HAMPSON (*Washington Sta. Bul. 328 (1936), pp. 29, figs. 7*).—Tables and charts showing the monthly indexes and weighted average index for each year during the period 1910–35 are included for the State and for each of the three types of farming districts. These indexes were computed by the method of aggregate, using the following 17 products: Wheat, oats, barley, corn, rye, all hay, potatoes, apples, beef cattle, veal calves, hogs, sheep, lambs, wool, poultry, eggs, and butterfat. The prices were those on the fifteenth of the month published in *Crops and Markets* of the U. S. Department of Agriculture. The weight used for each product was the average annual amount marketed by farmers of the State during the 5 yr. 1926–30. Tables are also included showing the weighted average annual prices, 1910–35, of the 17 products and the monthly indexes, 1910–35, of farm product prices.

"In the year 1920 agricultural prices in Washington rose to 214 percent of the average for the 5 yr. immediately preceding the outbreak of the World War, 1910 to 1914. In 1932, when farm prices were the lowest during the 26 yr. from 1910 to 1935, the index of farm product prices for Washington stood at only 60 percent of the pre-war average while the index for the United States was 65 percent of the pre-war average. Since 1933 the agricultural price level in Washington has not increased as much as that for the whole United States, indicating that agricultural prices have not been influenced as much in Washington as in other parts of the nation by farm relief and by the other factors which have operated to elevate prices of farm products generally throughout the country."

Apple prices received by Washington growers, C. C. HAMPSON (*Washington Sta. Bul. 326 (1936), pp. 59, figs. 11*).—Tables and charts are included and discussed showing by crop years 1922–33 the weighted average prices of packed apples delivered to shipping points for the Wenatchee-Okanogan district, the Yakima district, and the two districts combined (the Central Irrigated region of the State). The prices are shown for each of the 18 most important varieties

and for all other varieties combined. The data for 1928–29 to 1933–34 were obtained from the books of about 50 apple marketing organizations in the two districts. The data for the earlier years were gathered in a previous study (E. S. R., 63, p. 886). The samples included an average of 42 percent of the commercial shipments of the Central Irrigated region and 39.3 percent of the shipments of the State.

The average price of all varieties, grades, and sizes for the period was $1.05 per box. The prices for individual years ranged from 45 ct. to $1.66 per box. The average for the period 1922–29 was $1.23 and for the period 1930–33 72 ct. The average for Extra Fancy apples was $1.24, Fancy apples 95 ct., and grade C apples 75 ct. Of the apples 40 percent averaged Extra Fancy, 38 percent Fancy, and 18 percent grade C, and the remaining 4 percent were packed in miscellaneous grades. The average prices for the four leading varieties, which made up 87.2 percent of the shipments for the period 1929–33, were approximately as follows: Winesap $1.06, Delicious $1.40, and Jonathan and Rome Beauty 84 ct. The spread between the price of Delicious and those of other varieties has been decreasing since 1924. The average prices for the 12-yr. period for packed apples of the same varieties and similar quality were practically the same in the two districts.

An analysis of the prices received for canned Bartlett pears by canners on the Pacific coast—seasons, 1924–25 through 1935–36, H. J. STOVER (*California Sta. Mimeogr. Rpt.* [*49*] (*1936*), *pp.* [*1*]+*19, figs.* 7).—Analysis is made of the packs, carry-overs, shipments, prices, etc., of canned Bartlett pears, the levels of consumer incomes, prices of competing canned fruits, and other factors and their effects on the average f. o. b. prices received by Pacific coast canners of Bartlett pears.

Agricultural adjustment, 1933 to 1935 (*U. S. Dept. Agr., Agr. Adjust. Admin., 1936, pp. XVI*+*322, figs. 10*).—This report of the administrator of the Agricultural Adjustment Administration covers its activities "during the calendar year 1935, and to some extent is a review of the entire 3-yr. period beginning with passage of the Agricultural Adjustment Act in May 1933." The chapter headings are as follows: Production planning, replacement crops, agricultural-industrial relations, surplus-removal operations, commodity loans, consumers' counsel, agricultural exports and imports, legal aspects of administration, financial report, cotton, wheat, corn and hogs, tobacco, sugar, cattle, rice, peanuts, potatoes, rye, dairy products, and general crops. Appendixes include tables showing the tax collections and refunds by commodities and States; processing taxes, dates effective, and rates; and the expenditures by States for general administration and rental and benefits. The amount of trust fund operations is also shown.

Cooperation in agriculture, compiled by C. GARDNER (*Farm Credit Admin.* [*U. S.*], *Coop. Div., Bul. 4* (*1936*), *pp. III*+*214*).—An enlarged edition of this selected and annotated bibliography with special reference to marketing, purchasing, and credit (E. S. R., 56, p. 889).

Statistics of farmers' cooperative business organizations, 1920–1935, R. H. ELSWORTH (*Farm Credit Admin.* [*U. S.*], *Coop. Div., Bul. 6* (*1936*), *pp. IV*+*129 figs. 46*).—A statistical presentation of the activities of farmers' cooperative business organizations operative during the period.

Membership, financial, and operating status of cooperative country elevators in Kansas, 1931–1934, R. M. GREEN (*Farm Credit Admin.* [*U. S.*], *Coop. Div., Misc. Rpt. 7* (*1936*), *pp. 32, pls. 2*).—This study was made jointly by the cooperative division of the Farm Credit Administration and the department of agricultural economics and the agricultural extension service of the Kansas State College. Information was compiled from 380 records, each representing the business of a farmers' cooperative grain elevator for one of the crop years,

1931–34. Altogether, records were obtained from 133 cooperative elevator associations.

Results of the regulation of cotton gins as public utilities in Oklahoma, R. A. BALLINGER (*Oklahoma Sta. Bul. 230 (1936), pp. 16*).—The provisions of the State legislation regulating cotton gins as public utilities and the characteristics of gins as public utilities are discussed. Data are presented as to ginning rates in eastern and western Oklahoma and adjacent areas in Arkansas and Texas, and as to rates for ginning picked and snapped cotton in Oklahoma. The effects of rate regulation on prices paid for cotton by ginners, quality of ginning furnished, growers' profits, etc., are discussed.

The author finds that the State regulation has resulted in higher rather than lower ginning rates, that the practice by ginners of buying cotton at prices so high that money has been lost on the purchases has been encouraged, that ginning in the State is not conducted under conditions of monopoly comparable to other industries regulated as public utilities, and that the lack of monopoly conditions is the most important reason for many of the difficulties encountered in regulating gins and the comparatively little benefit received by farmers from such regulation.

Truck transportation of fruits and vegetables in western Maryland, R. RUSSELL (*Md. Agr. Soc., Farm Bur. Fed., Rpt., 20 (1935), pp. 270–284*).—Data for the year ended June 30, 1934, were gathered from 189 fruit and vegetable growers in three areas of Maryland west of Chesapeake Bay. Tables show for each of the areas the tonnage, value, and cost of marketing for different crops and the types of transportation used in marketing. Other tables show the average time spent per trip in marketing truck shipments in the markets used, the average yearly costs of operating trucks, and the costs per ton-mile grouped according to the size of the load hauled, average hauled in miles, and total miles traveled during the year.

Fruits and vegetables received in trucks in the Columbus wholesale market, 1929–1935, C. W. HAUCK (*Ohio State Univ., Dept. Rural Econ. Mimeogr. Bul. 86 (1936), pp. [2]+23, figs. 7*).—This is the eighth report of the series previously noted (E. S. R., 74, p. 718). The data gathered in 1935 are analyzed and comparisons are made with the years 1929–34, inclusive.

Roadside markets in Delaware, H. S. GABRIEL (*Delaware Sta. Bul. 201 (1936), pp. 25, figs. 3*).—In gathering the information as to practices of roadside markets, consumers' patronage of such markets, and the value of special types of packages, the following methods were used:

"Twenty-four of these roadside markets were visited and each proprietor was asked a number of similar questions. The answers to these questions gave a picture of just what the stands were doing. In order to get the consumer point of view 1,000 questionnaires were sent out, of which 279 were returned filled out in such a manner that answers could be used. For the package study, 200 special corrugated cardboard baskets were supplied by a large box company. These were used in the sale of apples, peaches, grapes, and tomatoes to test the consumer reaction to attractive packaging at a slightly increased cost."

The data obtained are presented in tables showing (1) for the markets, size of business, distance to nearest village, age of stands, products sold, sources of products, prices charged, methods of preparing products for market, attracting customers and advertising, number of men employed, etc., and (2) for the customers, the use made of markets and the reasons for patronizing or not patronizing the markets. The results of special package tests are briefly discussed.

Public produce markets of Michigan, O. ULREY (*Michigan Sta. Spec. Bul. 268 (1936), pp. 87, figs. 14*).—In this study the development and types of public

markets in the State are described. Analysis is made of the value and volume of produce sold; sales on public markets in relation to farm income; sales per capita of the market city; sales by groups of sellers, of home-grown and shipped-in produce, by groups of commodities, and in groups of buyers; seasonal distribution of sales; the use of public markets by farmers, including cost of selling, value of loads and annual sales, number and composition of loads, acreage and production, etc; the use of markets by truckers, dealers, retailers, hucksters, wholesalers, and consumers; and the operation and administration of public markets, including market prices, grades and standards, days and hours of operation, finances and records, ownership, control and administration, and layouts and facilities. Recommendations are made as to existing markets and the possibilities for and operation of additional markets.

New data on United States flour production since 1899, by States and by sizes of mills, H. WORKING (*Wheat Studies, Food Res. Inst [Stanford Univ.], 12 (1936), No. 8, pp. [2]+273–312, figs. 7*).—Consumption of flour in the United States was about 0.9 of a barrel per capita during each year 1921–29, but it dropped sharply during the depression and declined further when the processing tax was imposed. By 1934 the average consumption per capita had declined to slightly over three-quarters of a barrel. Large mills, producing 100,000 bbl. or more annually, provided 40.2 percent of the total flour output in 1899 and 80 percent in 1929. Their proportion declined slightly during the depression and was still only 79.9 percent in 1935.

Trends in the hog and pork trade in the United States, I. W. ARTHUR (*Iowa Sta. Bul. 346 (1936), pp. 239–278, figs. 7*).—Tables and charts are presented and discussed, the data being obtained chiefly from reports of the U. S. Department of Agriculture and from 143 packing plants showing for 1928 the number of hogs of different weights and grades slaughtered, the seasonal variation in numbers slaughtered, the nature of products sold, and the sources of supply.

A marked difference was found in the average weights of hogs received at the large central markets and in the average weights of hogs purchased and killed by packing plants in the different regions and in the same region. Areas with heavy corn production and proportionately few fall pigs tend to market the heaviest hogs. Pork packing, hog production, and corn acreage are increasing in the northwestern part of the United States and especially in the northwest Corn Belt. From 1915 to 1932 the central livestock markets located west of Chicago reshipped an increasing percentage of the receipts of slaughter hogs. Markets east of Chicago reshipped a declining percentage. From 1915 to 1926 the reshipments from Chicago increased. From 1926 to 1933 the trend at Chicago was reversed.

Europe as a market for American pecans (*U. S. Dept. Agr., Bur. Agr. Econ., Foreign Agr. Serv., 1936, F. S. 66, pp. [2]+25*).—Analysis is made of the European trend of production, supply, and consumption, and prices of competitive nuts, with a view to determinng the position of pecans in the markets of Europe and the European capacity to consume pecans.

Crops and Markets, [July 1936] (*U. S. Dept. Agr., Crops and Markets, 13 (1936), No. 7, pp. 217–256, figs. 3*).—Included are tables, reports, summaries, charts, etc., of the usual forms covering crop and livestock estimates, market reports, and the price situation.

RURAL SOCIOLOGY

The back-to-the-land movement in southern Indiana, H. E. MOORE and O. G. LLOYD (*Indiana Sta. Bul. 409 (1936), pp. 28, figs. 22*).—"This study was made to determine (1) the extent of the movement of population into some

of the poorer townships and into some of the better townships located in the same problem area of the State, (2) the characteristics of the newcomers, (3) the land tenure, kind of farming, poor relief and economic status of the newcomers in townships presumed to be submarginal and in nearby townships presumed to offer opportunities for great self-sufficiency, and (4) the effect, if any, of the back-to-the-land movement on local governmental costs."

Of the 608 families that moved back to the land between January 1, 1930, and June 1, 1934, 374 representative families were interviewed. Of these, 96 became full-time and 21 part-time farmer owners, 93 full-time and 19 part-time farmer renters, 21 farm hands, and 124 nonfarming rural residents. One hundred and fifteen settled in 9 better and 259 in 10 poorer agricultural townships. Tables and charts show for all townships, the better townships, and the poorer townships the findings as to amounts and sources of income, value of products of different kinds produced for sale and for home use, purchase price and indebtedness on owner-operated farms, livestock owned, land utilization, taxes, relief payments, school enrollments, etc.

Approximately 80 percent of the newcomers interviewed had either operated a farm, worked as a farm hand, or had been reared on a farm. Nearly 60 percent considered their residence permanent. The gross income per family averaged $479 in the better and $220 in the poorer townships. Of the gross income $332 was contributed by the farm in the better and $125 in the poorer townships. A higher percentage of the newcomers were full-time and part-time farmers in the better townships than in the poorer townships. Part-time farmers in all townships made larger incomes than full-time farmers. Fifty-six percent more livestock was kept on the farms in the better townships than on those in the poorer townships. The farms in the better townships averaged 30.6 crop acres as compared with 9.3 acres in the poorer townships. In the poorer townships 26 percent of the newcomers were on relief and received 18 percent of the relief paid, as compared with 6 and one-third of 1 percent, respectively, in the better townships.

Changes in population of counties in Michigan since 1930, J. P. THADEN (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 242–245*).—The author presents an analysis of shifts in the population of the State, as indicated in the Federal Census of April 1, 1930.

Immigrants and their children in South Dakota, J. P. JOHANSEN (*South Dakota Sta. Bul. 302 (1936), pp. 47, figs. 8*).—Present trends indicate that the movement of immigration into the State has completed its course. The foreign born settled largely during the period 1870–90, and when South Dakota became a State in 1889 it had more than 90,000 foreign-born inhabitants. When the western part of the State was opened to settlement from 1900 to 1910 considerable additions were made to the foreign-born population of the State. At present there is greater emigration than immigration.

Immigration introduces a population element which has an abnormal age and sex distribution. The second generation, the native of foreign or mixed parentage, goes through a similar cycle as the parent group. At first it grows rapidly, then it becomes stabilized, and then it declines as a population element. It has repeated the age distribution pattern of the parent group and will do so further to the extent that immigration ceases. The aging of the population is inherent in the cyclical nature of the immigration movement. Its sudden influx, combined with its recent sudden stoppage, tends to produce certain cyclical phenomena in the population statistics of the State. As the immigrant generation grows older, the related second generation will do likewise, but the native of native parentage has shown a relatively stable age distribution since 1900.

Three conditions affect the size of the families: Nativity, foreign and native; residence in rural-farm, village, and urban territory; and the year of immigration. Large families are found in those immigrant groups which have come to the United States relatively recently, while small families are more numerous in the immigrant nationalities which came relatively early. The foreign born in the State have settled in rural territory in somewhat greater proportions than have the natives. Their farm life, their traditions of family life, the status of women among them, their religious faiths, and their whole life outlook have all been favorable to a prolific family life. In urban communities in the State there is a much smaller proportion of children to women, native as well as foreign born, than in rural farm areas. Several facts and trends point toward a stable or decreasing population in the State in the near future.

Mobility of rural relief families in Tennessee, C. E. ALLRED, B. H. LUEBKE, and C. A. TOSCH (*[Nashville]: Tenn. Works Prog. Admin., 1936, Rpt. 14, pp. II+35, figs. 19*).—Seventy-three percent of the 2,236 relief families in nine representative counties of Tennessee have resided in the county since birth; 16 percent have moved into the county since 1930, the largest percentage during 1933. Fifty-eight percent of the heads of relief households live in the open country, 36.5 percent reside in villages, and 5.5 percent in towns. Of all occupational groups, farm owners have resided the greatest number of years in the county and farm laborers and croppers the least number. One-third of the heads of relief households are unemployed and seeking work. Fourteen percent of those have moved into the county during the last 5 yr. Thirteen percent of 6,549 relief cases in six representative counties had members returning from nonfarming occupation elsewhere. The return movement from points in Tennessee has been principally from places within the county or from adjoining counties.

[Rural relief and rehabilitation possibilities in Houston, Overton, Henderson, Jefferson, and Williamson Counties, Tennessee], C. E. ALLRED ET AL. (*[Nashville]: Tenn. Welfare Comm., 1935, Rpt. 3, pp. IV+45, figs. 26; 1936, Rpts., 4, pp. IV+33, figs. 19; 7, pp. IV+55, figs. 26; 10, pp. IV+47, figs. 26; Tenn. Works Prog. Admin., 1936, Rpt. 13, pp. IV+48, figs. 26*).—The Tennessee Experiment Station cooperated in these reports.

The families on relief in May 1935 in Houston County had 44.9 percent of dependents under 16 as compared with 39.1 percent for the general population in 1930. Of the families in the county in 1930, 63.8 percent of the colored families and 56.6 percent of the white families have been on relief. During May 1935, 29.6 percent of all the families were on relief. Net resources of 92.4 percent of all relief families are less than $500 each. Fifty-seven percent of all relief clients own or rent some land, but only 42.9 percent have holdings as large as 3 acres or more and only 30.4 percent give farming as their usual occupation. Farm relief families as well as nonfarm relief families are deficient in cows, hogs, poultry, gardens, and cans for preserving foods. Of the 365 families now on relief 48 percent have no livestock whatever; only 66.6 percent have gardens, although garden land is available to more than 90 percent of them; 47 percent have canned fruits and vegetables; 3 percent have automobiles; and 29.2 percent own their own homes.

Approximately 48 percent of the relief clients in Overton County are dependents under 16 yr. of age. Of the 30 negro families in 1930, only 9 have been on relief. Among white families 55.6 percent have been on relief and 23 percent were still on relief in January 1935. The debt of all relief families amounts to 54.5 percent of the total value of their property. In the farm tenant group the indebtedness is equal to as much as 117.5 percent of the total value of their property and in the farm labor group the percentage is 224.4.

The average size farm for relief families reported as operating farms (25.9 acres) is small in comparison with all farms of the county (62.4 acres). The average size farm of the open case families (18 acres) is much smaller than the average size farm of the closed case families (31.4 acres). Farm families on relief as well as nonfarm relief families are deficient in cows, hogs, poultry, gardens, and cans for preserving foods. Twenty percent of the open cases do not possess livestock of any kind. Of the families now on relief (open cases) only 58 percent have gardens, yet garden land is available to 93 percent of them. Approximately 50 percent of these cases do not have canned fruits or vegetables, and only 0.7 percent of them own automobiles. In June 1935 the rate of relief in the county was 32.4 percent, or over 2.5 times as high as the State average of 12.5 percent.

The families on relief in May 1935 in Henderson County had 10.3 percent heavier burden of dependents under 16 than had the families of the general population in 1930 (48.6 compared with 38.3 percent). On the average there are 0.9 employable males per relief family compared with 1.3 actually employed in the general population in 1930. Of the 380 colored families in the county in 1930, 77 of them, or 20.3 percent, have been on relief and 6.1 percent are still on relief. Among white families 17.7 percent have been on relief and 8.3 percent are still on relief. Net resources of 97.9 percent of all relief families average less than $500. The debt of all relief families is equivalent to 85.2 percent of the total value of their property, and in the farm tenant group the indebtedness is equal to as much as 102.2 percent. Only 40 percent of all relief clients, compared with 82.1 percent for all families of the county, own or rent some land. Farm relief families as well as nonfarm relief families are deficient in cows, hogs, poultry, gardens, and cans for preserving foods.

The families on relief in April 1935 in Jefferson County had 6.3 percent heavier burden of dependents under 16 than had the families of the general population in 1930 (44.2 compared with 37.9 percent). Of the 272 colored families in the county in 1930, 141, or 51.8 percent, have been on relief and 35.3 percent are still on relief. Among white families 26 percent have been on relief and 15.3 percent are still on relief. Net resources of 93.7 percent of the relief families average less than $500. The debt of relief families is equivalent to 56.7 percent of the total value of their property, and in the farm tenant group the indebtedness is equal to as much as 66.6 percent. Forty-nine percent of all relief clients, compared with 58 percent for all families in the county, own or rent some land. The average crop acreage of 28 farm cases that were closed on account of improved farming opportunity is 3.2 acres larger than the average for all cases but is 13 acres smaller than the county average of 27.1 acres. Practically all of the relief farmers have some livestock, but 25.7 percent of the open case farmers have no dairy cows, 38.6 percent have no hogs, and 15.2 percent have no poultry. Of the 643 families now on relief, 73.3 percent have some livestock, 85.8 have gardens, 78.8 have canned fruits and vegetables, and 7.3 percent have automobiles.

In April 1935, 9 percent of all the families in Williamson County were on relief. Work relief is the most important type of relief, over 50 percent of the families receiving this type. Nonfarm families received the highest average benefits. Approximately 36 percent of all persons on relief are employable and all but 44 relief families had at least one employable member. Twelve percent of the heads of relief families are female and over 63 percent of these have families to support. Net resources of over 95 percent of relief families average less than $500. Indebtedness of relief families, in percentage of all property, is over 50 percent. Only 21.6 percent of the relief families own or rent land and over 86 percent of their cropland was in corn, indicating a lack of crop

diversification. Families in the low relief districts of the county average more livestock units per farm and have greater crop diversification than do families in districts having a high relief rate.

Grundy County, Tennessee: Relief in a coal mining community, C. E. ALLRED, C. A. TOSCH, M. T. MATTHEWS, G. A. BAKER, W. E. COLLINS, P. H. SANDERS, and B. D. RASKOPF ([*Nashville*]: *Tenn. Welfare Comm., 1936, Rpt. 11, pp. V+51, figs. 15*).—According to this report in which the Tennessee Experiment Station cooperated, in January 1935 60 percent of the total population of Grundy County was on relief. Net resources of 94.2 percent of the relief families averaged less than $500. Total indebtedness of relief families, in percentage of all property, was over 50 percent. Fifty-six percent of relief farmers had no dairy cows, 43 percent no hogs, and 37 percent no poultry. Farmers of the general population average more than twice as much livestock as relief farmers, the averages per farm being 6.6 and 3.1 livestock units, respectively. Sixty-one percent of the families receiving relief were of the nonfarm group, most of whom were miners.

Public library service in South Dakota, W. F. KUMLIEN (*South Dakota Sta. Bul. 301 (1936), pp. 32, figs. 12*).—This study, made in cooperation with the Bureau of Agricultural Economics, U. S. D. A., covered the 74 public libraries of the State, most of which are located in cities, towns, and villages.

The majority of rural people in the State are without local public library service. In 62 out of 66 counties the only public libraries are those supported independently by the towns and villages. In these same 62 counties 92.2 percent of the borrowers are town people, while 7.8 percent are farmers. The former spend 43.1 ct. per capita for library service and the latter 4.8 ct.

In the four counties with county libraries, both town and country people share alike in the expense, management, and the service. The farm people respond quickly to library opportunity, there being a larger number of country borrowers than among those living in towns.

Although there are 70 independent town and village libraries in the State, the unit of their support in all but 26 cases is less than 1,500 people. When the supporting area is so small, either the cost per capita has to be excessive or else the quality of service suffers.

The solution of the problem for both town and country under South Dakota conditions seems to be the county library. There are probably 40 counties in the State where a county library system would serve both the town and country districts better than they are now being served and at not to exceed an average cost of from 50 ct. to $1.00 per capita per year.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

A possible intermediate step in the reorganization of rural elementary education in Iowa, B. MORGAN and W. H. LANCELOT (*Iowa Sta. Res. Bul. 200 (1936), pp. 279–330, figs. 4*).—The investigation reported in this bulletin, relating to the school year 1932–33, included 30 representative counties in the State. Its purpose was to ascertain the relative number of the rural children who might have, without any significant change in the cost of their education, attended existing graded schools instead.

The proposed reorganizations were planned on community bases. Each community included an existing town or consolidated school as a center and the nearby rural schools as tributaries. In the 30 counties studied it was found that the schools of 191 communities could be reorganized without increasing the cost in any community, the average saving being a little over 6 percent. If the proposed reorganizations were allowed to increase the cost as much as 8 percent

in certain communities, the schools of 227 communities could be reorganized at an average saving of about 5 percent.

The number of pupils enrolled per teacher ranged from 13 to 47 in the existing graded elementary schools. The median was 26.5. In the ungraded rural schools the enrollment per teacher ranged from 3 to 51 with a median of 15.1. In the reorganized systems, as planned, the range would have been from 25 to 35 with a median of 31.5. "It is apparent that a majority of the ungraded rural schools have enrollments too small to operate economically."

No alterations would have been necessary in the school plants of 159 of the 227 existing graded school systems which would have been attended by the rural children. The cost of necessary alterations in the plants of the remaining 68 was estimated to range from $180 to $20,000, to average $3,125, and in but three instances to exceed $10,000.

It is thought that the reorganization of rural elementary education in any community as described in this bulletin would probably increase somewhat the high school attendance of farm children.

Vegetable exhibitions: Their planning and management, L. E. SOMERS (*Illinois Sta. Circ. 455 (1936), pp. 28*).—Information on planning and arranging an exhibition and the scope and arrangement of home-garden exhibitions and commercial vegetable displays and suggestions for exhibitors choosing specimens for exhibit and preparing and arranging them and for judges as to standards, scoring, etc., are included.

Directory of activities of the Bureau of Plant Industry (*U. S. Dept. Agr., Misc. Pub. 238 (1936), pp. 130, figs. 2*).—The activities of the several divisions of the bureau are described. The field stations are listed by States with a statement of the lines of investigations carried on. An organization chart of the bureau and a map showing the location and character of the field stations are included.

Practical problems in botany, W. W. ROBBINS and J. ISENBARGER (*New York: John Wiley & Sons; London: Chapman & Hall, 1936, pp. IX+402, figs. 230*).—This text is organized on the basis of a series of problems on organization and composition of plants, nutrition of green and nongreen plants, growth, reproduction, dependence of plants on the conditions of their surroundings and how plants are fitted to these conditions, development and improvement of plants, classification, and economic importance to man.

Marketing principles: Organization and policies, J. F. PYLE (*New York and London: McGraw-Hill Book Co., 1936, rev. ed., pp. VIII+783, [pl. 1, figs. 28]*).—This is a revised edition of the textbook previously noted (E. S. R., 65, p. 683). The material is presented in chapters on some significant aspects of marketing; market potentials; buying motives, customs, and practices; marketing functions; the elements of a marketing organization—wholesale middlemen, retail functionaries, and chain stores; marketing methods; the marketing of agricultural, natural, and manufactured products and of services; some marketing problems connected with prices; financing marketing activities; some problems of risk in marketing; sales-promotional activities; problems of agricultural cooperative marketing; some aspects of formal social control in marketing; the place of executive control in marketing: and standards of marketing accomplishment.

George Washington and agriculture: A classified list of annotated references with an introductory note, E. E. EDWARDS (*U. S. Dept. Agr., Library, Bibliog. Contrib. 22 (1936), 2 ed., pp. V+77*).—The bibliography previously noted (E. S. R., 66, p. 191) has been enlarged to include 311 references.

FOODS—HUMAN NUTRITION

The nutritive value of animal tissues in growth, reproduction, and lactation.—III, The nutritive value of beef heart, kidney, round, and liver after heating and after alcohol extraction, W. H. SEEGERS and H. A. MATTILL (*Jour. Nutr., 10 (1935), No. 3, pp. 271–288, figs. 5*).—The investigation noted previously (E. S. R., 72, p. 722) was extended to similar studies of the alcohol-extracted material of beef heart, round, and kidney and a more detailed study of the liver.

There was little difference in the growth rate of rats fed the various materials at a 15-percent protein level in an otherwise apparently complete ration. After extraction with hot 95 percent alcohol in a continuous extractor for 60 hr., all of the materials promoted growth at a less rapid rate, particularly the extracted liver. Studies of the biological values of the proteins of the liver after various treatments showed that the alcohol extraction altered the protein to such an extent as to make it only slightly digestible. In vitro digestion experiments with all of the alcohol-extracted materials confirmed the low digestibility of the liver proteins after extraction. The other materials showed no appreciable loss in digestibility, leading the authors to conclude that, with the exception of liver, the difference between the extracted and unextracted meats can be ascribed solely to the removal of nutrients not adequately supplied by the yeast and cod-liver oil supplement.

The digestibility and biological value of the proteins of the liver were not lowered appreciably by heating at 100° C. for 2 weeks. At temperatures above 100° there was a progressive lowering of digestibility with increase and prolongation of the heat. The heart and kidney were not changed at 120° and the kidney not to any great extent at 130°. At higher temperatures these meats also resisted digestion both in vivo and in vitro. "These changes in digestibility probably play no role in the domestic cooking of meats, but are of importance in the preparation of pure proteins for nutrition studies."

The relationship of the distribution of body fat to the cooking losses with graded dressed poultry, W. A. MAW, R. HOLCOMB, E. E. RODGER, and A. M. FRANKLIN (*U. S. Egg and Poultry Mag., 42 (1936), No. 5, pp. 276–278, 314, 315*).—Roasters were graded according to the definitions of the Canadian market grades, A, B, and C, based on conditions of fleshing and fat distribution of dressed poultry.

Analyses made on the graded carcass showed that the A grade had a significantly higher percentage of total edible parts and less total waste than either B or C grade stock. The percentage of fat in the edible portion was found to be 21.9 percent for grade A, 14.7 for grade B, and 8.3 percent for grade C.

The results of analyses of roasters cooked according to the described method were found to follow closely those obtained on the uncooked carcass for percentage of total edible parts and waste. The percentage of fat lost was higher for A and B grades than for C, but the percentage of moisture lost was less for the higher grades, resulting in a drier meat for grade C.

Hydrogenated lard as a culinary fat (*Indiana Sta. Rpt. 1935, p. 44*).—This progress report summarizes the results obtained in a comparison of the flavor and shortening value of open-kettle rendered lard prepared from the leaf fat and fat back of each of 20 hogs fed a known soybean-corn-mineral ration and of hydrogenated lard from the same sources.

Biochemistry of bread making, C. H. BAILEY and R. C. SHERWOOD (*Indus. and Engin. Chem., 27 (1935), No. 12, pp. 1426–1430, figs. 5*).—This is a discussion, with numerous references to the literature, of the chemistry of wheat flour and other dough constituents, the colloidal chemistry of dough solution, the chemical

and physical changes in the fermentation of the dough mixture, and the process of saccharogenesis.

"Bread making is a dynamic process in which various organisms and tissues and numerous enzymes are involved. Flour from normal wheat contributes starch, sucrose, a trace of glucose, and the saccharifying enzyme β-amylase. Flour milled from germinated wheat or active malt extracts contributes α-amylase, the starch-liquefying enzyme. In doughs or flour suspensions to which small amounts of wheat or barley malt have been added, the rate of saccharification is greatly increased. The effect on sugar production is substantial and prompt. A decided increase in reducing sugar content was registered during the dough-mixing operation of only a few minutes' duration, and over 70 percent of the total reducing sugar produced during 1 hr. of autolysis of a yeast-free suspension was formed during the first 15 min.

"An acceleration of carbon dioxide production or 'gassing power' results when yeast is present, and rates of saccharification may be held at a fairly constant level during normal dough fermentation of about 5 hr., since the fermentable reducing sugar, chiefly maltose, is converted into alcohol and carbon dioxide about as rapidly as formed."

The influence of various factors, including altitude, on the production of angel food cake, M. A. BARMORE (*Cereal Chem., 13 (1936), No. 1, pp. 71–78, figs. 7; abs. in Jour. Colo.-Wyo. Acad. Sci., 2 (1935), No. 1, p. 19*).—Essentially noted from Colorado Station Technical Bulletin 15 (E. S. R., 75, p. 278).

The available carbohydrate of fruits.—Determination of glucose, fructose, sucrose, and starch, E. M. WIDDOWSON and R. A. MCCANCE (*Biochem. Jour., 29 (1935), No. 1, pp. 151–156*).—Determinations of available carbohydrate were carried out on the edible portions of 41 varieties of fresh fruits, and the results are reported in tabular form. The reducing sugars were determined in an alcoholic extract by the copper titration method. The glucose/fructose ratio was calculated from values obtained by the iodimetric procedure and estimates by Fehling's solution. Starch was determined in the residue from the alcoholic extraction by the takadiastase method. The sum of all the sugars was taken to represent the available carbohydrate.

Starch was present to the extent of 3 percent in the banana and in less amounts in the apple, pear, and tomato. Most of the fruits had approximately equal amounts of glucose and fructose. A few fruits contained no sucrose.

Citrus fruits in nutrition, O. D. ABBOTT (*Fla. State Hort. Soc. Proc., 48 (1935), pp. 61–64*).—In this contribution from the Florida Experiment Station, the author discusses the qualities which make citrus fruits valuable in the diet.

Investigations on fig preservation, S. KALOYEREAS (*Fruit Prod. Jour. and Amer. Vinegar Indus., 15 (1936). No. 8, pp. 240–243, figs. 4*).—The main purpose of the investigation was to improve the method of conserving fresh figs for a longer period of time. Fresh figs packed in layers separated by fig tree leaves have been successfully shipped as far as Germany. The use of hydrogen peroxide was found to be a satisfactory sterilizing treatment for the fresh fruit.

The experiments on dried fruit resulted in a practical method of sterilizing the fruit by using a mixture of CO_2 and CS_2 in special concrete sterilizing chambers.

Analyses showing the percentage of food constituents are given for several varieties of dried and fresh figs grown in different regions of Greece.

Byproducts of figs, particularly marmalade made from dried figs, were manufactured on a commercial scale as a result of investigations on preservation.

Some fruits of Hawaii: Their composition, nutritive value, and use, C. D. MILLER, K. BAZORE, and R. C. ROBBINS (*Hawaii Sta. Bul. 77 (1936), pp. 133, figs. 16*).—This bulletin has been prepared to supply information on the following widely used Hawaiian fruits: Avocado, banana (*Musa sapientum*), breadfruit, carambola (*Averrhoa carambola*), coconut, coffee (*Coffea arabica*), fig (*Ficus carica*), Isabella grape (*Vitus labrusca*), common guava (*Psidium guajava*), strawberry guava (*P. cattleyanum*), lemon, lime, litchi, mango, mountain or Malayapple (*Eugenia malaccensis*), Hawaiian orange (*Citrus sinensis*), papaya, passion fruit (*Passiflora edulis*), pineapple, poha (*Physalis peruviana*), soursop (*Annona muricata*), strawberry (*Fragaria chiloensis*), Surinam-cherry (Pitanga) (*E. uniflora*), tamarind, and watermelon.

For each of these fruits the general information given includes description—in some cases with photograph, history, special nutritive value, supply, and selected recipes. The sources of information on the nutritive value include many original data obtained by the authors, as well as some from the literature. Tabulated data are given on the proximate composition and total ash, calcium, phosphorus, and iron content of all of the fruits listed above except lime and lemon. Other tabulated data include the average weight and percentage of refuse of the various fruits, with description of the portions of the fruit considered as refuse; average measure and cost per pound as purchased and as edible portion; weight, measure, and cost of 100 calorie portions, and distribution of calories per 100 g and per pound of edible portion; the quantity of juice obtained from 1 lb. of the juice fruits as purchased; and qualitative values for vitamins A, B, C, and G for most of the fruits and quantitative values for a small number.

In a technical section of the bulletin, descriptions are given of the preparation of the fruit for chemical analysis and the analytical methods employed, including the technic for vitamin determinations.

Data on which the vitamin unit values were based are given for vitamins A and G in figs, guavas, papaya, pineapple, and pohas; vitamin B in the same fruits and also in soursop and tamarind, and vitamin C in all these fruits and also in coconut water, orange juice, and passion fruit juice.

A list of 75 references to the literature is appended.

[Strawberry sirup], G. A. SHUEY (*Tennessee Sta. Rpt. 1934, p. 21*).—This progress report describes briefly a method which has been developed for making a semi-sirup from strawberries suitable for use on ice cream, for blending in fruit punches, and for other flavoring purposes.

The mineral content of sirups, molasses, and soft sugars, O. SHEETS and R. W. PEARSON (*Mississippi Sta. Tech. Bul. 22 (1936), pp. 12*).—Published data on the content of ash and mineral constituents (iron, copper, calcium, and phosphorus) of sirups and molasses are summarized, and new data obtained by the authors, with the technical assistance of S. D. Sumerford and J. F. Weeks, are reported for samples of sorghum and sugarcane sirups made according to the usual farm methods and obtained from different localities throughout the State and for a large number of commercial sirups, molasses, and sugars. The data for the farm-manufactured products are tabulated as sorghum sirup evaporated on iron pans, sorghum sirup evaporated on copper and noniron pans, sugarcane sirup evaporated on iron pans, and sugarcane sirup evaporated on copper pans. In most cases the variety of sorghum or sugarcane used is given. Accompanying the data on commercial products are the name of the product and the description on the label.

The data show great variation in the mineral content of the sirups, molasses, and sugars. In general terms sorghum sirup has a high iron and copper content. Sugarcane sirup, especially when evaporated on an iron pan (E. S. R.,

73, p. 563) may be an excellent source of iron. Both sorghum and sugarcane sirups contain fair amounts of copper and phosphorus. "The blends of corn and refiners' sirup may be good sources of iron and copper, depending upon the quantity and quality of the refiners' sirup used. Molasses has a high mineral content, but unfortunately palatability decreases as its mineral content increases. . . . Brown sugar . . . may contain appreciable quantities of minerals, especially iron and copper. The lighter sugars have a low mineral content, but not as low as that of some of the sirups."

Wine in the diet, W. V. CRUESS (*Fruit Prod. Jour. and Amer. Vinegar Indus., 15 (1936), No. 9, pp. 260, 261, fig. 1*).—This paper from the California Experiment Station is a general discussion on the use and dietary values of wine.

Food fallacies and nutritional quackery, D. B. JONES ET AL. (*Amer. Pub. Health Assoc. Yearbook, 1935–36, pp. 58–63*).—In this report of the Committee on Nutritional Problems, evidence is given, with literature citations, refuting certain nutritional fads and fallacies such as the theory that proteins and starches are incompatible and should not be served together, incorrect use of the term acidosis and false claims concerning its cause, various diet systems for treatment of arthritis and hypertension, and false claims as to the relative digestibility of various foods. Other food fallacies are listed as "so fanciful and absurd that to the person of ordinary intelligence they need no refutation."

A long term experiment with rats on a human dietary, J. B. ORR, W. THOMSON, and R. C. GARRY (*Jour. Hyg. [London], 35 (1935), No. 4, pp. 476–497, pl. 1, figs. 7*).—This study differs in certain respects from previous attempts to assess the value of human dietaries by feeding experiments on rats. The diet used approximated closely the average diet of a working class community in Scotland as ascertained in an earlier dietary survey, and was given in daily variations to approximate more closely the food habits of human beings. At the beginning of the experiment 60 rats from 30 to 40 days old were arranged in two groups of 20 females and 10 males each. One group was given the diet as planned and the other the same diet supplemented with a definite amount of green vegetables and milk ad libitum. Breeding difficulties on the unsupplemented diet necessitated doubling the limited amount of milk in the original diet. With this change only, the experiment was continued for 2½ yr., a period covering 4–5 generations of rats and corresponding to 100 yr. or more of human life.

The rats on the diet supplemented with green vegetables and milk were healthy in every respect, while those without additional milk and green food showed "(1) a slightly impaired reproductive capacity, (2) a very markedly increased death rate due to increased susceptibility to an infection to which all rats were equally exposed, (3) a definitely slower rate of growth, (4) a lower hemoglobin content in the blood, and (5) a clinically poorer condition as judged by behavior and state of the coat." The authors conclude that if these results are applicable, "even to some extent, to human beings, they suggest that a large section of the human population is still far from the optimum state of nutrition, and that much could still be done by means of improved food supply to raise the resistance to infection and to improve the physique of human beings."

The comparative rate of absorption of various fats, H. STEENBOCK, M. H. IRWIN, and J. WEBER (*Jour. Biol. Chem., 114 (1936), No. 1, pp. C, CI*).—In this study at the Wisconsin Experiment Station, rats were fasted 48 hr., then were given 1.5 cc of melted fat of different kinds by stomach tube, and after absorption periods of 2, 4, 6, 8, and 12 hr. were sacrificed to analyze the intestinal residues for the amount of fat. The percentage absorption after a 4-hr. period for two partially hydrogenated vegetable oils was 52.8 and 53.8 percent, respec-

tively, for lard 57 percent, for corn oil 58.3, for butter oil 71, for halibut-liver oil 70.2, and for cod-liver oil 67.7 percent.

Inorganic salts in nutrition.—Changes in kidneys of rats fed a diet poor in inorganic constituents, P. P. SWANSON, C. A. STORVICK, and A. H. SMITH (*Jour. Biol. Chem., 114 (1936), No. 1, pp. 309-319*).—In continuation of previous studies (E. S. R., 73, p. 874) at the Iowa Experiment Station, 70 rats 37 days old were fed purified diets extremely low in inorganic constituents to show the effect on the excretory system. At the beginning of the experiment one group was anesthetized, another group after 21 days of experimental feeding, and two other groups after 42 and 63 days, respectively. At the same intervals, groups were removed from 69 rats which had been fed the low salt diet fortified with an adequate salt mixture. A second control group was given the adequate diet until the body weight equaled that of the experimental group at the end of 90 days and then these were sacrificed. The kidneys were extirpated and weighed, dried to constant weight, and analyzed for ash, calcium, and phosphorus.

The results showed that after 21 days of low salt intake the kidney had enlarged to the extent that the increment was twice normal. This weight was maintained for approximately 45 days. A regression due to the loss of total solids followed so that at the end of 90 days it was only 32 percent larger than at the beginning. For the same experimental period normal kidneys had increased 94 percent in weight, due to an increase in total solids. At the end of the period the kidneys of the rats on the low salt diets in relation to normal kidneys were definitely hydrated, showed a high proportion of ash, a high percentage of calcium, an increase in phosphorus, and no decrease in the proportions of ash, calcium, and phosphorus with advancing age. These results are discussed with reference to previous metabolic findings (E. S. R., 75, p. 724).

Effects of increasing the calcium of a diet in which calcium is one of the limiting factors, H. C. SHERMAN and H. L. CAMPBELL (*Jour. Nutr., 10 (1935), No. 4, pp. 363-371, figs. 2*).—As a part of an investigation to explain the superiority of the authors' diet B over diet A (E. S. R., 60, p. 787), the effect of the addition to diet A of an amount of calcium carbonate sufficient to increase the calcium content of the dry food mixture from 0.2 to 0.35 percent (representing the calcium content of diet B) was studied with rats throughout the natural life cycle and through successive generations.

The enrichment of the diet was followed by a more efficient utilization of food as calculated on the basis of energy value or protein content, better growth, earlier maturity, higher adult vitality as demonstrated particularly by the breeding records of the females, a longer period between the attainment of maturity and onset of senility, and, in less degree, in the average length of life. This increase was more significant for the males than the females. As the females had raised more young than the corresponding animals on diet A, it is thought that the added drain of calcium reserves may have accounted for the fact that the increase in length of life for the females was not as significant as for the males.

The authors conclude that "the previously reported improvement of an already adequate food supply is in part (though not solely) attributable to the enrichment of the calcium intake, and that the level of calcium intake most conducive to optimal well-being is significantly higher than that required for normal growth and maintenance."

Calcium involvement in magnesium deficiency, E. V. TUFTS and D. M. GREENBERG (*Soc. Expt. Biol. and Med. Proc., 34 (1936), No. 3, pp. 292-294*).—In

a preliminary report, further evidence is given in support of the hypothesis of McCollum et al. (E. S. R., 72, p. 876) that there exists a relationship between the metabolism of calcium and magnesium in the animal body.

Rats were fed on a high and a low calcium diet with magnesium at the same level for both diets. The animals fed the high calcium diet developed symptoms of magnesium deprivation, such as hyperemia, hyperirritability, and cachexia, a high percentage died from convulsions, and the remaining rats showed signs of malnutrition. The rats fed on low calcium diets remained in a normal state of health, and the females gave birth to normal young. Analyses of the heart, muscle, and kidney showed that the magnesium content was only slightly altered, while the calcium content of the heart and muscle was increased about 60 per cent over normal. The accumulation of calcium in the kidneys showed the mean for the control rats to be 22.2 mg of calcium per 100 g of wet kidney and that for the deficient rats to be 141 mg of calcium.

The calcium and phosphorus content of the body of the brook trout in relation to age, growth, and food, C. M. McCay, A. V. Tunison, M. Crowell, and H. Paul (*Jour. Biol. Chem., 114 (1936), No. 1, pp. 259–263*).—In a preliminary study at the [New York] Cornell Experiment Station, 3 groups of trout containing 50 individuals in each were isolated and all were fed a diet of beef liver. After 5 days, 25 trout from each group were preserved for analysis. The remaining trout were continued on the diet for 12 weeks. The calcium content was determined of the water, the beef liver, and the trout at the beginning and at the end of the experimental period. The results showed that the trout stored an average of 5.4, 6.2, and 5.9 mg of calcium for each of the 3 groups. One-fourth of this calcium originated in the food and three-fourths had been absorbed from the water.

In a second series the calcium and phosphorus were determined in 1-day-old eggs, at the "eyed" stage, in the "sac fry", in young trout before they were ready to eat the beef liver diet, and in the trout at intervals of 4 weeks for 10 mo. Calcium and phosphorus analyses were made of the fish, water, and liver. The results showed that in the egg sac stage the body calcium was markedly increased and that this calcium must have originated in the water. The phosphorus content was higher in the eggs and fry than the calcium, but after the fry started eating, the calcium content rapidly increased until it was nearly equal to the phosphorus content.

Calcium and phosphorus needs of preschool children, A. L. Daniels, M. K. Hutton, E. M. Knott, O. E. Wright, and M. Forman (*Jour. Nutr., 10 (1935), No. 4, pp. 373–388, figs. 4*).—The previously noted study of the calcium needs of children of preschool age (E. S. R., 71, p. 881) has been extended, with longer metabolism periods and slight modifications in the method of food preparation, as described in detail in the report on the protein needs of children of this age group (E. S. R., 74, p. 130). The children, who were between 36 and 66 mo. of age, were cared for as in the previous study, and the analytical methods were for the most part the same. As the calcium retentions were found to be similar to those in the earlier study, the results of both studies were grouped for analysis according to the calcium ingestion per kilogram of body weight at intervals of 5 between 35 and 100 mg, with corresponding phosphorus and nitrogen ingestion. Scatter diagrams were also prepared to show the relation of calcium ingestion to retention in the present study and in both series of the earlier study.

Wide variations in both calcium and phosphorus retentions were obtained at similar ingestion levels whether calculated in terms of weight or of height. High retentions were interpreted as being due to previous depletion. It is concluded that an intake of from 45 to 50 mg of calcium per kilogram of body

weight or from 7 to 9 mg per centimeter of height is sufficient for the age group studied, provided the calcium is available and sufficient vitamin D is allowed. The phosphorus needs of children in the same age group are estimated to be from 55 to 60 mg per kilogram, or from 9 to 10 mg per centimeter, depending on the presence of an adequate amount of vitamin D. Calcium retentions between 7 and 9 mg, and phosphorus retentions between 6 and 9 mg, per kilogram are considered to be normal for well-developed children.

Egg yolk and bran as sources of iron in the human dietary, E. McC. VAHLTEICH, E. H. FUNNELL, G. MACLEOD, and M. S. ROSE (*Jour. Amer. Dietet. Assoc., 11 (1935), No. 4, pp. 331–334*) —This is a continuation of the studies made on the availability of iron in egg yolk and bran (E. S. R., 71, p. 725).

The participants, two healthy young women, carried out two iron balance studies of 9 days each between menstrual periods. Each study was preceded by a day of low iron intake, followed during the periods of study by an average intake of 5.7 and 5.3 mg of iron, 3 mg of which was furnished by the egg yolk and bran.

Iron balances showed that the iron of egg yolk and of bran prepared by steaming and toasting are equally efficient in maintaining iron equilibrium in the human adult.

Tables are given showing daily food consumption and the iron balances in 3-day periods.

The iron requirement of the normal human adult, G. E. FARRAR, JR., and S. M. GOLDHAMER (*Jour. Nutr., 10 (1935), No. 3, pp. 241–254*).—The four subjects in this investigation included three young adult men and one woman who had been subsisting for periods of 316, 160, 110, and 41 days, respectively, on accurately measured constant simple diets in connection with another investigation. The iron content of their diets was determined at frequent intervals, and toward the end of the experiment the excretion of iron in the feces and urine and the iron, red blood cell, and hemoglobin content of the blood were also determined.

The average daily values for intake and outgo during the iron balance periods lasting 31, 5, 5, and 17 days, respectively, were intake 5.2 mg and iron content of feces 5.2 mg, 7.7 and 7.6, 7.3 and 7.2, and 8.3 and 8 mg, respectively. The average iron content of the urine was 0.2 mg for each of the subjects. Blood iron values were 56.3, 52.8, 54, and 47.8 mg per 100 cc and hemoglobin by the Sahli method, in which 16.6 g per 100 cc represents 100 percent, were 98, 94, 97, and 80 percent, respectively. The total menstrual blood loss in the single period included in the experimental period of the female subject was determined roughly as 33 cc.

In the diet of the subject remaining on experiment for 316 days, the available iron calculated by the Hill method amounted to only 3 mg when the total iron of the diet was 5 mg daily.

The authors conclude that the iron requirement of the normal adult male is not more than 5 mg daily.

Sexual differentiation in the storage of iron by the rat, H. STEENBOCK, J. SEMB, and E. C. VAN DONK (*Jour. Biol. Chem., 114 (1936), No. 1, p. CI*).—Iron analysis of the rat at the Wisconsin Experiment Station showed that the amount of iron in the young at birth depended upon the amount stored by the mother, that the females accumulated larger iron stores than the males, that during pregnancy these iron stores were rapidly depleted as the amount in the fetuses increased, that after parturition the depleted stores were rapidly increased to normal levels, and that the iron stores decreased after castration of the females. Injection of follicular hormone increased the iron in immature

females as compared to that of litter mate controls, indicating that the storage in the female was influenced by ovarian secretions.

Studies on aluminum.—II, The storage of intravenously injected aluminum in the dog, D. F. EVELETH and V. C. MYERS (*Jour. Biol. Chem., 113 (1936), No. 2, pp. 467–471*).—Using the aurin method described on page 743, the authors studied the storage of aluminum in the tissues of 4 dogs given 10 daily intravenous injections of 1 mg per kilogram of soluble aluminum. At 78, 125, 137, and 150 days, respectively, the dogs were killed and the tissues analyzed.

The results indicated that part of the injected aluminum was primarily stored in the liver and spleen, but also in the kidney; that part of it was promptly excreted in the bile and urine; and that the stored aluminum was retained in the tissues of the dog for a long time. One dog killed 53 min. after the injection of 1 mg of soluble aluminum showed an immediate distribution of aluminum in the tissues. The values obtained by Underhill and Peterman (E. S. R., 62, p. 585) were found to be too high.

Metabolism in the rat of the naturally occurring arsenic of shrimp as compared with arsenic trioxide, E. J. COULSON, R. E. REMINGTON, and K. M. LYNCH (*Jour. Nutr., 10 (1935), No. 3, pp. 255–270, fig. 1*).—Arsenic as present in shrimp was found to be far less available for storage in young rats than when fed at the same level as As_2O_3. During the first 3 mo. of the feeding period 18 percent of As_2O_3 incorporated in the diet at a 17.9-percent level was stored as against 0.7 percent for the same amount of arsenic in shrimp. The total quantity stored was not significantly increased by feeding the element for an added 9 mo. There was no evidence of toxicity from the arsenic in either form after 12 mo. of feeding.

In 2 human subjects the ingestion of shrimp in amounts furnishing 1,180γ and 980γ arsenic was followed by rapid and complete elimination of the arsenic. Inorganic arsenic, although excreted more slowly than shrimp arsenic, was apparently eliminated more completely than in the rat.

These results are considered to be of interest "not only for the light which they throw on the metabolism of arsenic but also as additional evidence that the manner in which inorganic elements are used in the body depends upon the source or form in which those elements are presented."

[Fluorine studies of the Tennessee Station], G. A. SHUEY (*Tennessee Sta. Rpt. 1934, pp. 20, 21*).—This progress report gives data on the fluorine content of the peel and spray residue on the peel of apples treated with various sprays and washed or not washed; and of apple flesh, peel, flesh and peel, raw cabbage, green spinach, corn meal, rye bread, whole wheat grain and flour, and wheat bran.

The vitamin A and D content of canned salmon, G. M. DEVANEY and L. K. PUTNEY (*Jour. Home Econ., 27 (1935), No. 10, pp. 658–662*).—In continuation of previous studies (E. S. R., 73, p. 732), the vitamin A and D content was determined of from 2 to 4 brands each of commercial canned chum, pink, red, and Chinook salmon by a modified form of the method of Sherman and Munsell (E. S. R., 54, p. 89) for vitamin A and by the usual line test technic for vitamin D. The modified diet for vitamin A determination consisted of vitamin A-free casein 18 percent, irradiated yeast 5, untreated yeast 5, Osborne and Mendel salt mixture 4, sodium chloride 1, hydrogenated vegetable fat 10, and starch 57 percent. The salmon was purchased in retail stores and was prepared for the feeding tests in a manner similar to that used for home consumption. The price of the canned salmon increased in the order named above. The results were as follows:

Vitamin A tests on 2 brands of chum gave values of 0.25 and 0.3 international units per gram, pink 1 unit each, red 2.5 and 4 units, and Chinook 4 and 8 units. Vitamin D tests on 2 brands of chum gave values of 1.9 and 2.6 units per gram, on 4 brands of pink 4, 6.2, 7.1, and 7.6 units, on 1 brand of red 8 units, and on 3 brands of Chinook 2.1, 2.6, and 3.9 units. The two brands of chum were about equal in vitamin D potency to 2 brands of Chinook but lower than that of the third brand.

It is noted that "canned salmon is a relatively inexpensive source of excellent protein. The fact that certain varieties of salmon are rich in vitamin A and that all varieties contain considerable vitamin D gives added significance to the place of this food in the diet, especially the low-cost diet."

The effect of quantitative underfeeding and of vitamin A deficiency on the tissue lipids of rats fed diets low in cholesterol, H. L. GILLUM and R. OKEY (*Jour. Nutr., 11 (1936), No 4, pp. 303–308*).—Analyses are reported of the lipid constituents of the readily separable tissues of three groups of eight rats each which had been kept for 70 days after weaning on a low sterol basal diet (1) ad libitum, with yeast supplement and cod-liver oil heated to destroy vitamin A; (2) limited in quantity to that eaten by the A-deficient group, but with adequate vitamin supplements, and (3) ad libitum, with adequate vitamin supplements.

"The percentages of lipid constituents found varied rather markedly from tissue to tissue, but apart from neutral fat the differences observed in the lipid constituents of the individual tissues when considered with relation to the nutritional state of the animals were slight, occasionally inconsistent, but generally in the direction to be expected from earlier work on tissue lipids in undernutrition. There was no clear evidence of a specific effect of A deficiency."

The effect of quantitative underfeeding and of vitamin A deficiency on the liver lipids of rats fed diets with added cholesterol, H. L. GILLUM and R. OKEY (*Jour. Nutr., 11 (1936), No. 4, pp. 309–317, figs. 3*).—In this study the basal diet and plan of feeding were the same as reported in the paper noted above, with the exception that for approximately half of the animals in each group 1 percent of cholesterol was added to the diet when the rats were 6 weeks of age. After about 50 days of cholesterol feeding all of the animals were killed and their livers analyzed for lipids.

The size of the livers and their fatty acid content were less for the undernourished and A-deficient animals, both with and without cholesterol, than for the controls. Although variations in free cholesterol in the liver on the different diets without added cholesterol were slight, and undernourished animals showed a tendency toward a slightly higher concentration of free cholesterol. In the cholesterol-fed animals the livers of the vitamin A-deficient group had a lower concentration and a lower absolute quantity of ester storage than the other group, but poor assimilation is suggested as the cause rather than a specific effect such as previously observed in vitamin B deficiency. The cholesterol-fed animals also had a slightly lower phospholipid content. The relatively small livers of the undernourished animals contained a higher concentration and almost as high an absolute amount of cholesterol ester as the grossly enlarged livers of the controls.

Vitamin A and carotene.—XXI, The elimination of vitamin A from the livers of rats previously given massive doses of vitamin A concentrate, A. W. DAVIES and T. MOORE (*Biochem. Jour., 29 (1935), No. 1, pp. 147–150, fig. 1*).—In continuing their studies on high concentrations of vitamin A in the livers of rats, previously noted (E. S. R., 73, p. 419), the authors presented data showing the rate at which the liver reserves of vitamin A are used.

Adult rats receiving large doses of vitamin A concentrate stored in their livers an average of 18,000 B. u. per gram of liver, representing a supply sufficient to satisfy the theoretical requirement of the rat for about 100 yr. if used at the rate corresponding to the minimum physiological requirements. When these rats were put on a vitamin A low diet, a rapid depletion of the vitamin resulted in 12 weeks, after which there appeared to be no further fall of the liver reserve.

Quantitative experiments on the occurrence of vitamin B in organs, J. R. BRODIE and F. L. MACLEOD (*Jour. Nutr., 10 (1935), No. 2, pp. 179–186, figs. 2*).—The distribution of vitamin B in the bodies of rats reared on diets containing different amounts of the vitamin was studied by feeding their tissues as the sole source of the vitamin to depleted rats.

In the bodies of the rats reared on Sherman diet B, the liver contained the largest amount of the vitamin, followed closely by the heart. Kidney tissue contained about one-half and brain tissue about one-third as much of the vitamin per gram of tissue, while blood, spleen, and lungs in the amounts fed showed only traces.

Of the rats receiving as the sole source of vitamin B tissues from rats fed for 1 mo. on a diet lacking in vitamin B, only those receiving brain tissue lived longer than the controls, but lost weight rapidly. Rats receiving the tissues of other animals fed for 1 mo. on diet B supplemented with extra yeast showed increased storage of vitamin B in some of their tissues, particularly the muscle, liver, kidney, brain, and lung.

It is concluded that the storage of vitamin B in the body of the rat may be changed within certain limits by varying the amount of this vitamin in the diet.

The occurrence of cataract in rats fed on diets deficient in vitamin B_2, M. C. BOURNE and M. A. PYKE (*Biochem. Jour., 29 (1935), No. 8 pp. 1865–1871*).—The experiments of Day and associates in which cataract was regularly produced in rats on a diet deficient in vitamin B_2 (E. S. R., 72, p. 730) have been repeated, with results differing from those of Day et al. in two respects. The incidence of cataract was much lower, and dermatitis was a much more consistent symptom of the B_2 deficiency than cataract.

In a small group of rats receiving cystine as a supplement to the basal diet no cataract developed, but in view of the low incidence of cataract in the animals not receiving cystine no importance could be attached to the negative results. The substitution of rice for cornstarch did not alter appreciably the incidence of cataract.

The authors conclude that "the relationship of cataract to vitamin B_2 deficiency still remains obscure. The results of our experiments suggest that some dietary factor may be concerned in the production of cataract, but whether this factor is the whole of the vitamin B_2 complex or some component of it, or whether it is some new and unrecognized substance, is not yet established."

Skin lesions of the rat associated with the vitamin B complex, L. R. RICHARDSON and A. G. HOGAN (*Missouri Sta. Res. Bul. 241 (1936), pp. 36, pl. 1, figs. 4*).—This is a detailed report of an extension of the studies differentiating the denuded condition and the dermatitis brought about in rats by a deficiency of different factors of the vitamin B complex (E. S. R., 75, p. 727).

Complete directions are given for the preparation of the various supplements tested. The vitamin B (B_1) carrier to supplement the vitamin B complex-free basal diet was prepared by irradiating in solution a water extract of dried brewer's yeast. Preliminary experiments showed that if this extract was ir-

radiated in a dry state from 50 to 60 percent of the antineuritic vitamin (B_1) and from 75 to 85 percent of the antidermatitis vitamin were destroyed, while if irradiated in solution over 90 percent of the antineuritic and less than 10 percent of the antidermatitis vitamin were destroyed. The method of irradiation is described in detail.

The flavine concentrate was prepared by a modification of the method of Kuhn et al., with final purification as described by Stare (see p. 889). An oil was prepared from cornstarch by extracting the starch with hot 95-percent ethyl alcohol, removing the alcohol by distillation under reduced pressure, extracting the residue with ethyl ether, and removing the ether by evaporation. Wheat germ oil was prepared by extracting the germ with U. S. P. ethyl ether and evaporating off the solvent.

In attempts to identify the antidermatitis factor, the possibility suggested by the effectiveness of cornstarch oil that the active agent might be one of the unsaturated fatty acids was tested by examining a number of vegetable oils and also cod-liver oil for effectiveness as a curative agent for the dermatitis. Wheat germ oil proved very effective, but corn oil, flaxseed oil, walnut oil, and cod-liver oil were ineffective or only slightly effective. More direct evidence that the antidermatitis agent is not a fatty acid was obtained by extracting yeast thoroughly with ethyl ether and testing both the extract and the residue. The extract proved completely inactive, while the yeast residue had lost none of its activity. Although the antidermatitis factor is contained in some oils, the authors "regard it as a water-soluble vitamin because of its presence in a water extract of yeast and in tikitiki. Our tentative hypothesis assumes that the vitamin is coupled with some other constituents of the oil, though as yet we have been unable to effect a complete separation."

The differentiation of two types of lesions was shown experimentally by denuding rats on the basal ration supplemented with tikitiki and by inducing a symmetrical dermatitis on the basal ration supplemented with the irradiated yeast extract and flavine. The denuded condition was cured by the addition of the flavine concentrate and not by the wheat germ oil. The dermatitis was healed by the wheat germ oil but not by flavine. The animals made satisfactory gains in weight when the flavine concentrate was added to the tikitiki supplement and when both wheat germ oil and flavine concentrate were added to the irradiated yeast extract supplement. Further data showed that a combination of vitamin B_1 crystals, wheat germ oil, and flavine was not adequate for normal growth of the rats and that it was inferior to tikitiki and flavine. This evidence, according to the authors, indicated strongly though not conclusively that a fourth factor was required for normal growth. When the Smith and Hendrick and the Goldberger "rat pellagra" diets were fed to rats with dermatitis and to rats with the denuded condition, the dermatitis was healed but not the denuding. When these diets were supplemented with 2 mg of flavine, the denuded condition was healed. The evidence indicated that in the rations used by earlier workers flavine was the limiting factor.

The antidermatitis factor was adsorbed on English fuller's earth from aqueous solution of tikitiki at pH 4.8 and only partially adsorbed when the solution was strongly acid. It was also adsorbed on charcoal in both neutral and acid solutions. It was unstable to heat, since autoclaving at a neutral or slightly acid reaction reduced the activity of yeast approximately 60 percent. The vitamin was dialyzed through parchment paper. The activity of the antidermatitis factor was only slightly reduced in wheat germ oil, tikitiki, and the water extract of yeast by exposure to a 1,500-w Mazda bulb for 10 hr. at a distance of 6 in. The unit for the antidermatitis vitamin proposed is the "daily dose re-

quired to heal the dermatitis in 50 percent or more of the rats when the symptoms are definitely positive but not unduly severe."

In an extensive discussion the authors attempt to correlate their observations with those of other workers. Some of the discrepancies pointed out are differences in the method of irradiating yeast, in the sources and levels at which the vitamin B carriers were fed, in the method of estimating the amount of the antineuritic vitamin in the vitamin B preparations, and in the constituents of the basal ration, some of which may contain the antidermatitis factor. Concerning the composition of the vitamin B complex and the designation of its different factors, the following statement is made:

"There are certainly three members of the vitamin B complex that are required by the rat: (1) The antineuritic vitamin, B in our terminology; (2) vitamin G which we regard as flavine, designated by us as the antidenuding factor; (3) the antidermatitis vitamin (provisionally designated as H); (4) a fourth as yet unrecognized. The fourth is assumed because the three mentioned do not permit a normal growth rate, and do not permit the rats to attain normal mature weights. If there is more than one type of dermatitis it will be necessary to add a fifth."

Pathological skin changes in the tail of the albino rat on a diet deficient in vitamin G, S. G. SMITH and D. H. SPRUNT (*Jour. Nutr., 10 (1935), No. 5, pp. 481–492, figs. 6*).—Earlier findings (E. S. R., 69, p. 472) were confirmed, and it was further shown that the changes were independent of the initial age of the rat and the season of the year. However, similar changes occurred to some extent in rats suffering from a deficiency of vitamin A or vitamin B. There were no appreciable changes in rats on the Steenbock rickets-producing diet.

The authors suggest three possible explanations for the pathological changes observed: "(1) They may be due to chronic inanition, (2) in the case of the vitamin A and vitamin B deficiencies there may be a secondary shortage of vitamin G due to inanition or faulty absorption, (3) vitamins A, B, and G may all be necessary for the protection of the tissues involved. Under these circumstances the pathological changes described may occur when any one of them is lacking."

What is vitamin G?—A survey of the literature, H. E. MUNSELL (*Jour. Home Econ., 28 (1936), No. 5, pp. 320–328*).—This critical review of the literature from 1926 to 1935 on the differentiation of the vitamin B complex with special reference to vitamin G (B_2) closes with the following summary:

"The literature indicates that if at the present time we use the term 'vitamin G' we must consider two factors—(1) flavines and (2) a still unidentified factor vitamin B_6 essential to prevent and cure a condition in rats closely resembling pellagra in man. Both of these factors are, however, distinct from the P–P factor of Goldberger and associates and probably also from the chick antipellagra factor of Elvehjem and coworkers.

"In reading reports on vitamin G, consideration should be given to the fact that the term vitamin G as used by different investigators does not always designate the same value, necessitating caution in interpretation of the results reported. In much of the assay work the term actually covers flavine values only, although in most cases this must be determined by the reader, since it is not so stated. In a few studies it is used to refer to the antipellagra factor, while in still others where the author used it synonymously with the antipellagra factor he was really dealing with the flavine factor only.

"The significance of the two factors, flavine and vitamin B_6, in human nutrition is at present unknown. Inasmuch as many of the vitamin G values given in the literature have been determined by methods giving flavine values only, it follows

that they are of little use in planning diets until we know more of the role of flavines in human nutrition."

Standard methods of vitamin D bio-assay of milk, E. M. NELSON ET AL. (*Amer. Pub. Health Assoc. Yearbook, 1935–36, p. 64*).—In this report the topics to be studied for the development of a standard method for the bio-assay of vitamin D in milk were noted. They were duration of the test period, method of feeding the milk, suitability of basal diets for control animals, methods of preserving the milk during the period of test, and the suitability of a reference oil as a standard for comparison.

An essential dietary factor found in yeast and liver extract distinct from vitamins B_1, B_2, B_6, and flavins, C. A. ELVEHJEM, C. J. KOEHN, JR, and J. J. OLESON (*Jour. Biol. Chem., 114 (1936), No. 1, pp. XXXI, XXXII*).—In this investigation at the Wisconsin Experiment Station, rats failed to grow and died in from 4 to 8 weeks without gross symptoms on a diet of highly purified casein, dextrin or sucrose, butter or cottonseed oil, salts, cod-liver oil, and vitamin B_1 concentrate. The addition of B_2 concentrate, or a flavine preparation, or a combination of the two prepared from liver extract, did not improve the growth in rats. The 5-percent original liver extract produced a phenomenal growth response. The diets supplemented with 12 percent of white corn, 2 percent of liver extract, or 4 percent of baker's yeast gave equal growth responses. This factor was present in the alcohol-ether precipitate of liver extract and was destroyed by autoclaying.

Effects on three types of animals of injecting the new factor curative of pellagra-like symptoms due to egg white, J. G. LEASE, E. KELLY, and H. T. PARSONS (*Jour Biol. Chem., 114 (1936), No. 1, p. LXI*).—In this study at the Wisconsin Experiment Station, a water-soluble factor prepared by digesting liver residue with papain and reextracting the dried extract with methanol was found to cure a severe dermatitis and a nerve disorder caused by dietary egg white in three types of animals. The curative dose for the rat was 0.25 cc given intraperitoneally 3 times a week, for the chick 0.5 cc injected 3 times a week, and for the rabbit 4 cc a day. This factor was not identical with vitamins B_1 or B_2.

The preparation and nutritional value of hepatoflavin, F. J. STARE (*Jour. Biol. Chem., 111 (1935), No. 3, pp. 567–575, figs. 3*).—A method is described in which the procedure for preparing hepatoflavine concentrate from horse liver is considerably shortened. Crystalline flavine was prepared from the concentrate by slow crystallization. When flavine alone was fed to rats and chicks on a diet deficient in vitamin B_2 a pellagra-like dermatitis developed, which was cured by a supplementary substance present in the liver and not adsorbed by fuller's earth. Both the flavine and the unknown factor were necessary for normal growth.

Hepatoflavin and pernicious anemia, F. J. STARE and L. D. THOMPSON (*Soc. Expt. Biol. and Med. Proc., 33 (1935), No. 1, pp. 64, 65*).—Purified hepatoflavine was found to give negative results when substituted for liver extract in the treatment by intramuscular injection of five patients with pernicious anemia. Further proof of the nonidentity of flavine with the factor in Lilly liver extract effective in pernicious anemia was afforded by the observation that the liver extract lost none of its activity following irradiation in 10-percent NaOH solution for 24 hr. with a 300-w light bulb, a process known to change flavine into inactive photoflavine.

Observations on the anemia caused by deaminized casein, A. G. HOGAN and R. E. GUERRANT (*Jour. Biol. Chem., 114 (1936), No. 1, pp. LI, LII*).—Further studies (E. S. R., 72, p. 892) at the Missouri Experiment Station indicated that

lactalbumin was ineffective and that commercial dried ovalbumin and dried yeast at 18 percent levels were effective in curing anemia caused by deaminized casein. Autoclaving yeast or casein caused a loss of the antianemic activity. Hydrolysis with strong acids caused a loss in casein. Between 2.5 and 5 percent of casein was required for preventing anemia when the ration contained 10 percent deaminized casein. A minimum of from 5 to 10 percent deaminized casein was required to produce anemia. Milk, egg yolk, water extract of yeast, wheat germ oil, and a number of animal tissues showed no curative action in amounts of from 100 to 400 mg daily.

Some observations on diet and dental disease, R. A. FERGUSON (*Jour. Amer. Dental Assoc., 22 (1935), No. 3, pp. 392–401*).—The results recorded from dental examinations of 4,602 white recruits from various sections of the country entering the U. S. Navy showed that those from rural districts had fewer defective teeth than those from industrial and densely populated centers. The number of defective teeth, including extractions, was highest among boys coming from New England and the Middle Atlantic States and lowest among those coming from the South and West. Perfect teeth were shown by 372 boys from the country as against 30 from the city. The beneficial effects of the sun's rays and of the diet consisting of eggs, milk, fruits, vegetables, and meat on the boys from rural sections are given in explanation of the results. An extensive review is given of the literature on the effects of diet on dental health.

TEXTILES AND CLOTHING

Oxidation of wool: Photochemical oxidation, A. L. SMITH and M. HARRIS (*Jour. Res. Natl. Bur. Standards [U. S.], 17 (1936), No. 1, pp. 97–100, fig. 1*).—The photochemical decomposition of wool, as evidenced by decrease in cystine content and increase in alkali solubility, ammonia nitrogen, and sulfate sulfur, was observed to be accelerated by acids and decelerated by alkalies. The extent to which wool is degraded during irradiation is directly proportional to the decrease in cystine content and to the increase in alkali solubility. The sulfur content of untreated and of acid-treated wool decreased during irradiation. The data suggested that part of the sulfur in wool is converted to hydrogen sulfide, some of which is subsequently oxidized to sulfuric acid.

The influence of fibre length on the milling properties of merino wool, J. B. SPEAKMAN and T. SUN, (*Jour. Textile Inst., 27 (1936), No. 6, pp. T171–T176, figs. 2*).—For yarns of the same count and twist, the rate of milling shrinkage was found to decrease with increasing fiber length in the case of Australian 64's merino wool. This result, contrary to that observed with Wensleydale wool, is due in part at least to the greater crimpiness and scaliness of merino wool fibers.

When yarns of the same strength and count were compared, simple relationships between fiber length and milling properties could not be deduced for merino wool. In most cases the short wool again was superior but with exceptions. Evidently the relationship between fiber length and milling properties is a complex function of yarn as well as fiber characteristics.

Quality guides in buying women's cloth coats, C. L. SCOTT (*U. S. Dept. Agr. Leaflet 117 (1936), pp. 8*).—This leaflet of the series noted previously (E. S. R., 73, p. 573) contains practical advice on types of coat suitable for various purposes and special qualities to consider in coat fabric, linings and interlinings, workmanship and pressing, fur and other trimmings, and fastenings.

HOME MANAGEMENT AND EQUIPMENT

Family finance: A study in the economics of consumption, H. F. BIGELOW (*Chicago: J. B. Lippincott Co., 1936, pp. XI+519, [figs. 7]*).—"Family Finance is a study in the economics of consumption, written from the point of view of the individual family." Its purposes are "to suggest in considerable detail methods and devices by which the individual family may immediately go about improving its way of living. And since we can solve our personal problems only if we become intelligently aware of the social and economic situation outside the home, a second purpose is to help families develop a point of view and work out a technic of planning and management which will facilitate continuous and satisfactory adjustment to the constantly changing conditions in the world around them."

Parts 1 to 3 discuss the modern American family; its wants and income: the importance of choice in the American economy; the satisfaction of wants by wise purchasing, production for use in the home, and cooperative and collective spending; and some problems of family finances—food, clothing, housing, household operation, the automobile, and health, education, and recreation. Part 4, the strategy of family finance, includes chapters on family budgeting in theory and practice, the long-time plan, adjusting family expenditures to changes in family needs, adjusting family expenditures to changing business conditions, the place of credit in family finance, and providing for the future.

Changes in standards of consumption during a depression, I. H. GROSS and J. POND (*Michigan Sta. Spec. Bul. 274 (1936), pp. 30, figs. 2*).—Standards and levels of consumption of a small section of the farm population in Michigan in 1929 and 1932 were compared from schedules collected by one investigator in 1932 from 114 families living on owner-operated farms in Clinton County, Mich., where the type of farming was diversified. The families, all of whom were living on the same farms during both years of the study, averaged 4.4 persons. The average size of the farms in 1929 was 113 acres, valued for tax assessment at $6,211 and in 1932 practically the same acreage, with an assessed value of $5,606. In 1929 the average cash income available for living was $1,389, with only one below $500, one above $5,000, and about two-thirds $1,000 and above. In 1932 the average cash income was $664, with the incomes of 46 families below $500, none above $2,000, and 90 percent below $1,000.

The consumption of food during the 2 yr. was estimated both in quantities produced and purchased and in cost with 1932 prices adjusted to 1929 levels. The total changes in consumption of food were relatively slight, the amounts increasing by an average of 1.8 percent and the adjusted retail valuation by 2.5 percent. The proportion of purchased food shifted from 16.3 percent of the total in 1929 to 13.6 percent in 1932. The principal increases in home production of foods were in baked goods, cottage cheese, milk and cream, and vegetables. Less fruit, both purchased and home produced, was used in 1932 than 1929. The decrease in home-produced fruits was attributed to a poor apple crop in 1932. Many families stated that they "lived better" in 1932 than in 1929 because the prices obtainable for farm produce were so low that they preferred to eat the food themselves rather than sacrifice it on the market. This is also illustrated by the changes in money value of foods adjusted to 1929 levels. The money value of purchased foods in 1932 was 6 percent less than in 1929 and the calculated money value of home-produced foods was 6 percent more. The total money value of all foods in 1932 was $965.95 compared with $942.17 in 1929, or an increase of 2.5 percent.

The total expenditures for clothing per family changed from $146.29 in 1929 to $74.10 (or $97.88 adjusted to 1929 levels) in 1932. The highest percentage

decreases in clothing expenditures were for the sons and daughters from 18 to 23 yr. of age, the percentage decreases being 46.2 and 52.5 percent. The absolute expenditures for this age group, however, were higher than for any other. Practices of renovating and making over garments, particularly dresses, coats, and overcoats, increased markedly.

The houses in the present study represented a rather superior group as compared with the average for Michigan homes in the 1934 Federal survey and also for Iowa homes in the same survey as noted in Iowa Station Research Bulletin 174 (E. S. R., 72, p. 557). Expenditures for repairs and improvements in housing decreased in 1932 by 59 percent. Additions and replacements in house furnishings were both at a lower level than in 1929.

In household operation 51 percent more families used wood in place of coal for heating and 7.5 percent more for cooking in 1932 than in 1929. There were no mechanical refrigerators in either year, but as the initial cost of electrification had decreased during the period there was an increase in the use of electricity for lighting and various types of household equipment amounting to 31 percent for washing machines, 35 percent for electric irons, and 13 percent for vacuum cleaners.

There was an increase in unpaid taxes and nonpayment of interest in mortgages and a decrease in the number of life insurances carried. In general the most important changes are summarized as follows:

"First changes made consciously by families were predominantly in increase of home production of food and purchase of cheaper foods, in curtailing of clothing expenditures, in less use of car, in fewer entertainments, and removing the telephone. An actual important change was in the nonpayment of financial obligations, although that was not listed as a conscious choice."

The methods by which the housekeeping activities are carried on in the home of the married woman who works full time outside the home (*Rhode Island Sta. Rpt. [1935], pp. 30, 31*).—This progress report summarizes some of the findings in the analysis of 44 records obtained from married women in different parts of the State engaged in full-time outside occupations. Reasons for the work, types of work, and the nature of the help in the housework are included.

Some factors affecting improvement in Iowa farm family housing, M. G. REID (*Iowa Sta. Bul. 349 (1936). pp. 323–361, figs. 10*).—The author reports the results of two housing surveys, one made in 1934 including 18,789 farm dwellings, and the other made in 1935 including 8,798 dwellings in Iowa towns and villages of less than 2,500 population.

Factors discussed are income, tenancy, cost of materials, labor costs, tax on dwellings, credit for dwelling improvement, electricity, and legislation.

A study of ovens used for domestic cooking purposes (*Indiana Sta. Rpt. 1935, p. 43*).—In this progress report thermal efficiencies are given for a gas range oven used with manufactured gas, the same range oven with a bottled gas and conversion burners, and the oven of a range designed for use with the bottled gas. Information is also given on the relative efficiencies of the ovens in preheating, maintaining the temperature during baking, and temperature variations in different parts of the oven.

MISCELLANEOUS

Atlas of American agriculture: Physical basis, including land relief, climate, soils, and natural vegetation of the United States (*U. S. Dept. Agr., 1936, pp. [231], pls. 8, figs. 373*).—This publication, prepared under the super-

vision of O. E. Baker, includes the following: Land Relief, by F. J. Marschner, noted on page 749; Temperature, Sunshine, and Wind, by J. B. Kincer (E. S. R., 61, p. 313); Frost and the Growing Season, by W. G. Reed (E. S. R., 40, p. 209); Precipitation and Humidity, by J. B. Kincer (E. S. R., 49, p. 313); Soils of the United States, by C. F. Marbut (E. S. R., 74, p. 304); and Natural Vegetation, by H. L. Shantz and R. Zon (E. S. R., 52, p. 520).

Alaska Agricultural College and School of Mines Agricultural Experiment Station, College, Alaska, 1934: Progress report, January–December, G. W. GASSER (*Alaska Col. Sta. Bul. 4 [1935], pp. 51, figs. 16*).—The experimental work reported is for the most part noted elsewhere in this issue. Meteorological data are also included.

Forty-eighth Annual Report of [Indiana Station], 1935, J. H. SKINNER and H. J. REED (*Indiana Sta. Rpt. 1935, pp. 90, figs. 29*).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

Report of Moses Fell Annex Farm, Bedford, Indiana, June 1936, H. J. REED and H. G. HALL (*Indiana Sta. Circ. 219 (1936), pp. 16, figs. 8*).—The experimental work summarized is for the most part abstracted elsewhere in this issue.

Report of the Puerto Rico Agricultural Experiment Station, 1935, [A. LEE] (*Puerto Rico Sta. Rpt., 1935, pp. [2]+34, figs. 15*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. The general agricultural situation in Puerto Rico and the activities there of bureaus of the U. S. Department of Agriculture are also discussed.

Forty-eighth Annual Report [of Rhode Island Station, 1935], B. E. GILBERT (*Rhode Island Sta. Rpt. [1935], pp. 40*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological data (pp. 38, 39) are also included.

Forty-seventh Annual Report [of Tennessee Station], 1934, [C. A. MOOERS ET AL.] (*Tennessee Sta. Rpt. 1934, pp. 39*).—The experimental work reported is for the most part noted elsewhere in this issue.

Michigan Agricultural Experiment Station Quarterly Bulletin, [May 1936], edited by V. R. GARDNER and A. A. APPLEGATE (*Michigan Sta. Quart. Bul., 18 (1936), No. 4, pp. 209–278, figs. 7*).—In addition to the usual abstracts of bulletins and journal articles, this number contains articles abstracted elsewhere in this issue and the following: Field Peas Offer Possibilities as a Summer-Seeded Green Manure, by H. R. Pettigrove (pp. 263–265), and Distribution of Red and White Wheat in Michigan, by H. C. Rather (pp. 266–268).

Annual summary of publications, B. C. PITTMAN (*Utah Sta. Circ. 108 (1936), pp. [4]*).—Abstracts of Bulletins 257–271 and Circular 107 are given, with lists of reprints and leaflets.

In memory of Charles Embree Thorne, 1846–1936 (*Ohio Sta. Admin. Circ. 3 [1936, pp. 14], figs. 3*).—This includes an account of Dr. Thorne's contribution to agricultural research, by A. Vivian, and a number of tributes (E. S. R., 74, p. 577).

NOTES

Colorado College and Station.—L. D. Crain retired September 1 as head of the department of mechanical engineering and vice director of the station, but is continuing as building superintendent. Robert E. Trimble, meteorologist in the division of irrigation investigations for 45 years, retired July 1 and has been succeeded by H. O. Caperton. Melvin S. Morris, associate in range management, resigned September 1 to accept a similar position in the University of Montana and has been succeeded by Terrill D. Stevens as assistant professor and assistant in range and pasture management. Hazen B. Pingrey, assistant in rural economics, resigned August 1 to become assistant agricultural economist in the New Mexico Station. Recent appointments include Dr. H. S. Wilgus, Jr., on July 1, as head of a new section of poultry and Dr. Ralph Weihing, instructor in agronomy and assistant agronomist in the Washington College and Station, as assistant in plant industry.

Georgia University.—*Science* notes that the Georgia Rehabilitation Corporation has deeded to the university a tract of 1,900 acres of land estimated to be worth about $50,000. It is announced that the College of Agriculture and the George Foster Peabody School of Forestry will use the land for experimental purposes.

Illinois University and Station.—Ruth A. Wardall, head of the department of home economics since 1921, died July 15. Miss Wardall was a native of Illinois and a graduate of the university in 1903 and received the M. A. degree in 1907. She was a pioneer worker in home economics, heading the department in the South Dakota College from 1903 to 1906, the Ohio State University from 1907 to 1913, and the University of Iowa from 1913 to 1921. She had long been active in the home economics section of the Association of Land-Grant Colleges and Universities, and was joint author with Edna N. White of A Study of Foods (1914) and with C. W. Taber of Economics of the Family (1923). On September 1 the vacancy caused by her death was filled by the appointment of Lita Bane.

Dr. L. J. Norton has resumed his duties as professor of agricultural economics after 18 months' leave as vice president of the Production Credit Corporation of St. Louis and will be associated with research as well as teaching and extension.

Missouri University and Station.—An additional wing to the home economics building has been completed and equipped, practically doubling the amount of space available for this subject.

Two new greenhouses have been built. One of these, given over to experiments in plant genetics, is equipped with artificial lights in order to regulate conditions during cloudy weather and short winter days. The other greenhouse will be used to study the effect of temperature on the important grasses of the State, both soil and air temperatures being subject to control.

Dr. John Milton Poehlman has been appointed instructor in field crops.

New Mexico College and Station.—The station recently began work on a Bankhead-Jones project entitled Studies of the Revegetation of Southwestern Ranges by Controlled Grazing, Utilization of Run-off Water, and Reseeding. Under this project studies are also being conducted in connection with the determination of the carrying capacity of southwestern ranges. A laboratory has been fitted up at the headquarters of the livestock ranch controlled by the

college, and equipment has been installed for determining soil moisture, making germination tests of seeds, and recording precipitation and temperature data.

A new home economics building costing with equipment over $64,000 has been completed.

Dr. Ray Fife, State director of agricultural education in Ohio, has been appointed president, assuming his new duties in August. Other recent appointments include J. V. Enzie as assistant professor of horticulture and assistant horticulturist, vice Dr. A. L. Stark resigned; Dr. Kenneth W. Smith as assistant professor of animal husbandry and assistant animal husbandman; and T. R. Timm as assistant agricultural economist.

Oklahoma College and Station.—In cooperation with the U. S. D. A. Bureau of Plant Industry the station has completed the erection of a gin building and the installation of machinery for ginning foundation gin stocks as well as experimental seed plats. The building is a brick and tile structure intended to be fireproof, operated by an electric motor, and containing two gin stands, with the possibility of installing a third, as well as a drier for the drying and proper humidification of the cotton before ginning.

Appointments in the college and station since July 1 include the following as assistant professors: Adlowe L. Larson, agricultural economics; Bruce R. Taylor and Hilton M. Briggs, animal husbandry; Garth W. Volk, soils; Walther H. Ott, poultry husbandry; and Franklin A. Romshe, horticulture. W. B. Maddox has been appointed creamery superintendent.

Pennsylvania College and Station.—The resignations are noted of A. C. McIntyre as assistant professor of forest research; H. E. Longenecker, Dr. J. J. Thomas, and Dr. C. O. Jensen as instructors in agricultural and biological chemistry; M. G. Huber, D. D. Stevenson, Florence Brown, and W. I. Bull as instructors in agricultural engineering, forestry, botany, and forestry extension, respectively; E. G. Fouse and Howard J. Bonser as assistants in agricultural economics; and R. K. Ziebarth as assistant in forestry. Recent appointments include as assistant professors Dr. O. D. Burke, Dr. George F. Johnson, E. Macklin John, Walter W. Simonds, and Dr. James J. Reid in plant pathology extension, agricultural extension, agricultural economics, forestry extension, and bacteriology, respectively; as instructors Allen H. Bauer, Dr. Leita Davy, and W. S. Jeffries in plant pathology extension, agricultural and biological chemistry, and agricultural extension, respectively, and Raymond R. Moore and Joseph T. Radel in forest research; and as assistants William L. Barr in agricultural economics and Ronald A. Morck and William L. Porter in agricultural and biological chemistry.

South Dakota Station.—Dr. Kurt W. Franke, head of the department of agricultural chemistry since 1927, died September 15 at the age of 47 years. Born in St. Paul, Minn., Dr. Franke received a number of degrees from the University of Virginia and that of doctor of philosophy from the University of Minnesota in 1927. In South Dakota he began a comprehensive study of alkali disease, which in 1931 became cooperative with several bureaus of the U. S. Department of Agriculture. The results indicated the responsibility of some organic selenium compound, the isolation of which he was attempting. A recent tribute by Dr. R. A. Gortner in *Science* points out that in 9 years he "made a major contribution to agricultural science and accomplished far more than many men accomplish in a lifetime of endeavor. Twenty-two papers under his authorship had already appeared, and the experimental work on several more had been completed."

Tennessee University.—C. A. Willson, dean of the College of Agriculture and professor of animal husbandry since 1923 and associated with the institution

since 1910, died October 12 at the age of 57 years. A native of Michigan, he was the recipient from the Michigan College of the B. S. A. degree in 1906 and of the M. Agr. degree in 1923, as well as of the M. S. A. degree from the University of Missouri in 1910. He served as assistant in animal husbandry in the Kansas College and Station in 1906–7 and as instructor in animal husbandry in the University of Missouri from 1907 to 1910. He was the author of Arithmetic in Agriculture and Rural Life, the third edition of which was published in 1935.

Utah College and Station.—With the cooperation of several other agencies the station has undertaken an inventory of the agricultural resources of the State and the present extent of their utilization. The study includes soil, range, and irrigation surveys and an economic analysis of the agricultural enterprise. The inventory has been concluded for Washington and west Millard Counties, while in Utah County and the Uintah Basin it is complete in all phases except the soil survey, which is expected to be finished early in 1937.

Blanche Condit Pittman, publications editor and librarian for 20 years, resigned July 1 and has been succeeded by Gladys L. Harrison. Leaves of absence for the year have been granted to Dr. B. L. Richards, professor of botany and plant pathology, and David A. Burgoyne, secretary of the station, the duties in the latter position being assumed by F. Wilcken Fox, secretary of the bureau of visual instruction in Brigham Young University. Delmar C. Tingey, associate agronomist, has returned from 8 months' leave spent as associate agronomist with the U. S. D. A. Soil Conservation Nurseries at Pullman, Wash.

Florida Citrus Research Laboratory.—A laboratory for basic research in the biological and chemical problems of handling and processing citrus fruits and their products has been established by B. C. Skinner at Dunedin, Fla. Dr. R. B. Harvey, professor of plant physiology and botany in the Minnesota University and Station, has been granted a year's leave of absence to take charge of the laboratory, which now has a staff of four coworkers. Attention will be given to improved methods of processing, utilization of cull citrus, and other phases of citrus production and marketing.

Second International Congress for Microbiology.—This Congress was held from July 27 to August 1, 1936, at University College, London, with an attendance of over 1,000. The Congress was organized into eight sections, dealing, respectively, with the general biology of micro-organisms; the viruses and virus diseases in animals and plants; bacteria and fungi in relation to disease in man, animals, and plants; economic bacteriology, under the presidency of Dean and Director R. E. Buchanan of the Iowa College and Station; medical, veterinary, and agricultural zoology; serology and immunochemistry; microbiological chemistry; and specific immunization in the control of human and animal diseases. An invitation from the United States to hold the third congress on the Atlantic seaboard in 1939 was accepted.

Necrology.—Dr. Justus W. Folsom, associated with the entomological work of the Illinois University and Station from 1900 to 1923 and since 1925 entomologist of the field station of the U. S. D. A. Bureau of Entomology and Plant Quarantine at Tallulah, La., died September 24, aged 65 years. He was the author of Entomology With Special Reference to Its Biological and Economic Aspects (1906).

Charles Fitzhugh Talman, librarian of the U. S. D. A. Weather Bureau since 1908 and widely known for his bibliographical work, contributions to the popular press, and books of reference and other meteorological services, died July 24 at the age of 62 years.

INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R." to those of the experiment stations in Hawaii and Puerto Rico; "Can" to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

Abaca bunchy top disease, 207.
Abies numidica, insects affecting, 376.
Abortion—*see also Brucella abortus*.
  agglutination test for, Ind. 840.
  agglutination tests, results, Hawaii 534.
  control, Mich. 691; Mont. 691; N.J. 691; Tenn. 845.
  control in Jamaica, 538.
  control in Oregon, 101.
  control program, N.Dak. 537.
  economic loss from, Md. 256.
  establishment and maintenance of abortion-free herds, [Conn.]Storrs 252.
  Federal project, results of retests in, 101.
  immunization studies, Ind. 840.
  importance of bacterin treatment in, 399.
  in a naturally infected herd, Calif. 106.
  in Finland, biology and importance, 397.
  in mares, 104.
  in swine, transmission to cattle, Mo. 102.
  project, cooperative, general progress of, 101.
  relation of blood and milk sera agglutination titers to udder infection, Md. 256.
  resistance of individual cows to, S.C. 107.
  role of *Trichomonas* in, 543.
  studies, Colo. 252; Ohio 397; Tex. 103.
  transmission by ceased reactors, Wis. 537.
  transmission from immune dams to progeny, Mo. 102.
  trichomonad, in cattle in Netherlands, 695.
Absorption tube, improved liquid, 585.
Abutilon moth as leaf defoliator of cotton, 518.
Acacia species, South African, cyanogenetic glucosides in, 538.
Acacipetalin, chemical constitution, 538.
Acanthocephala from carnivores in Trinidad, 655.
Acanthocephalus—
  confraterna, notes, Fla. 658.
  fermorata, notes, Fla. 658.
Acanthoscelides obtectus, *see* Bean weevil.
Acarophenax tribolii, parasite of *Tribolium*, U.S.D.A. 524.
Accounting, farm, *see* Farm account.
Acetalydehyde, effect on glucose fermentation by *Lactobacillus lycopersici*, 606.
Acetic acid series, higher members, 514.
Acetone in aqueous solution, analysis, 160.
Acetphenetidin, preparation from *p*-aminoacetanilid, 149.
Acetylmethylcarbinol—
  effect on glucose fermentation by *Lactobacillus lycopersici*, 606.
  in fermentation liquors, determination, 589.
Achroia grisella, occurrence and biology, 82.
Achromobacter on dressed poultry, action at chill temperatures, 97.
Acid phosphate, *see* Superphosphates.
Acids—
  amino, *see* Amino acid(s).
  fatty, *see* Fatty acids.
  organic, secretion by plant roots, 186.
Acrobasis caryae, *see* Pecan nut casebearer.
Acrobeles complexus, notes, Fla. 637.
Actinea richardsoni, cause of heavy losses of range sheep, N.Mex. 846.
Actinomyces—
  aerobic acid-fast, in milk due to an udder infection, 836.
  alni n.sp., provisional name, 187.
  elaagni n.sp., provisional name, 187.
  isolation from scab lesions on potatoes and beets, 644.
  of albus group, treatise, 320.
  scabies, control, 787.
  soil, and potato scab, Vt. 644.
Actinomycetes of soil, phylogenetic study, N.Dak. 445.
Acuaria anthuris, parasite of crows, 851.
Adelges abietis, hibernating female, relation to survival of spring generation, Conn.[New Haven] 657.
Adelina sp. affecting *Tribolium*, U.S.D.A. 524.
Adsorbability, effect of organic structure, Minn. 581.
Aedes, spp., transmission of virus of equine encephalomyelitis by, 848.
Aegeria—
  exitiosa, *see* Peach borer.
  pictipes, *see* Peach borer, lesser.

Aegyptianella pullorum outbreak in Peking ducks, 700.
Aeolus mellillus in Canada, 817.
Aerators, sintered Pyrex glass, preparation, 607.
Aerobacter aerogenes, acid production by, Mass. 436.
African coast fever, relation to turning sickness, 693.
Agamermis decaudata, life history, 234.
Agglutination—
low-titer, significance, 101.
tests, comparison of methods, Mo. 102.
Agricultural—
Adjustment Act—
and cotton, 413.
and livestock, 413.
and national recovery, 554.
and tobacco, 413.
marketing agreements under, 413
Adjustment Administration activities, 1933 to 1935, U.S.D.A. 869.
adjustment concept, fundamental significance, 554.
adjustment program, sociological implications of, 713.
adjustment programs, proposed changes, 268.
adjustment, validity of fundamental assumptions underlying, 268.
books, American, selected list, U.S.D.A. 562.
census of 1935, 268.
chemistry, *see* Chemistry.
colleges, *see* Iowa, Kansas, Massachusetts, *etc.*
community adjacent to large city, social adjustment in, [Conn.]Storrs 277.
credit system, production, of 1933, 556.
economic facts basebook of Iowa, Iowa 859.
economics—*see also* Farm economics.
bibliography, U.S.D.A. 411.
future pattern of research in, 554
research in, 554.
Education, International Congress, notes, 288.
engineering, *see* Engineering.
experiment stations, *see* Experiment stations.
experimentation and research, True's history of, editorial, 737.
extension, *see* Extension.
industrial, and mineral development of Kentucky, 269.
information, improvement in accuracy and scope, 268.
journals, new, 143.
labor—*see also* Labor.
in United States, 1915–35, bibliography, U.S.D.A. 556.
power, and machinery costs on farms in 1933, Ind. 863.
machinery—*see also* Combines, Harvesting, Thresher, *etc.*
and minor equipment, value, Ind. 863.
Agricultural—Continued
machinery—continued.
electric motors for, 265.
for use in plant breeding plats, 706
hitches for, S.Dak. 406.
new types, Idaho 701.
marketing acts and schemes, treatise, 276.
outlook charts, U.S.D.A. 120.
planning and farm economists, 268.
planning, place in national economy, 268.
planning, progress and problems in, 268
policy for Montana, evolution of, Mont. 710.
policy for United States, 269.
products—
cost of production, *see specific crops*
imports and estimated acreage displaced, U.S.D.A. 712.
international trade of United States, developments affecting, 554.
marketing, *see* Marketing.
of Oklahoma, prices and purchasing power, Okla. 269.
production-consumption balance, Mich. 559.
program, evaluation in terms of economic theory involved, 268.
program in Canada, 268
program, long-time, things to be considered, Okla. 412.
Prorate Act of California, constitutionality, 554.
relief, *see* Relief.
research, plant anatomy in, 43.
resources of South Dakota, 271.
situation, Okla. 269, 412.
statistics, State problems in, 268.
tenancy, *see* Farm tenancy.
Agriculture—
American, and trade agreements program, 269.
American, atlas, U.S.D.A. 892.
analysis on Sun River irrigation project, Mont. 860.
and land use in Oregon, graphic summary, Oreg. 121.
and rural life, arithmetic in, treatise, 277.
commercial, relation to population trends, 527.
contribution made to national income by, U.S.D.A. 868.
Department of, *see* United States Department of Agriculture.
electricity in, *see* Electricity.
in Italy, effect of spring rains, 12.
in Michigan and Canadian trade agreement, Mich. 268.
in Montana, readjusting, Mont. 270, 550, 860.
in Norway, motorization of draft operations, 265
in Southwest, goals for, 269.
in Turkey, basis of, treatise, 39.

Agriculture—Continued.
in Wisconsin, forces affecting types of farming, Wis. 272.
income parity for, U.S.D.A. 555.
relation to climatic features, P.R. 746
relation to monetary and credit policies, Okla. 412.
specialized commercial, of Santa Clara Valley, 162.
Agriolimax agrestis as tobacco pest, U.S.D.A. 655.
Agriotes mancus, see Wheat wireworm.
Agromyza maculosa, notes, Conn.[New Haven] 657.
Agropyron caryopses, germination, 625.
Agrostis canina, development of spikelet in 458.
Agrostis spp., soil tests of, 625.
Agrotis, see Cutworms.
Ailanthus altissima, abnormal method of branching, 320.
Air conditioning—
and electric refrigeration, 734.
and heating, treatise, 267.
by sun, 707.
equipment for homes, 267.
Air, promoting circulation, small inexpensive stirrer for, U.S.D.A. 76.
Air, stirring within desiccators, 409, 438.
Airplane—
dusting, studies, Mass. 512.
travel, insect problems created by, 809
Alabama argillacea, see Cotton leaf worm.
Alaska College and School of Mines, report, 893.
Albumin, egg—
addition to pituitary synergist, effect, 328.
attempts to isolate toxic factor, Wis. 504.
bound water and phase equilibria in, 234.
effect of variations in ionic strength on apparent isoelectric point, 148.
grades of firmness, photographic score for measuring, 248.
pellagra-like symptoms due to, new curative factor, effect on types of animals. 889.
structure, 680.
watery, chemical nature, 394; Wash. 88.
Alcaligenes viscosus dissimilis, notes, Iowa 97.
Alcohol—*see also* Butyl, Ethyl, *and* Methyl alcohol.
and gasoline blends as fuel for automotive engines, 405.
as fuel for automotive engines, 405.
oily, from wheat-germ oil, vitamin E properties, 742.
production from potatoes, Idaho 701.
Aleyrodes citri, see Whitefly, citrus.
Alfalfa—
and sweetclover as companion crops, competition, Wash. 38.
and timothy mixtures v. nitrogen-treated timothy, Ohio 331.
Alfalfa—Continued.
bacterial wilt, control, Colo. 207.
bacterial wilt, field studies, Wyo. 401.
bacterial wilt, resistance, 500.
black stem disease, Idaho, 637.
breeding, N.Dak. 474; N.J. 616; Nebr. 195.
culture experiments, Wyo. 39.
culture on beach land of Louisiana, 472.
cutting test, Fla. 616; Hawaii 330; N.Mex. 37.
cutting tests, relation to fall weather, Mich. 616.
cutting under different fertilizer treatments, effects of time and frequency, [Conn.]Storrs 194.
damping-off, control by seed treatment, 494.
disease due to selenium intoxication, S.Dak. 691.
effect of frost of January 1934 in India, 12.
effect of phosphatic fertilizers, Mont. 453.
effect of sodium nitrate on number and growth of nodules, 451.
effect of spring-burning natural mulch material, Iowa 35.
ensiling by A. I. V. method, feasibility, Wis. 535.
fertilizer experiments, Idaho 616; N.Mex. 36; R.I. 767; Wash. Wyo. 39.
green, v. green Sudan grass, feeding value, Hawaii 395, 534.
growth, effect of soil reaction, Ohio 331.
hay and lespedeza hay for dairy cows, comparison, N.C. 99.
hay and meal, carotene in, factors affecting, 678.
hay as ration for dairy cows, Ind. 830.
hay, carotene in, effect of processing, N.J. 684.
hay, chopped, storing in ventilated containers, 528.
hay cut at different stages, effect on vitamin A in butter, 245; Ind. 831.
hay, effect of mechanical processing on digestion, Ohio 388.
hay, feeding value, Ind. 834; Mich. 683.
hay for fattening lambs, N.Mex. 87.
in Michigan, Mich. 333.
inheritance of tolerance to soil conditions, N.J. 616.
injury by potato leafhopper, 517; Ky. 518.
Ladak, adaptation for range improvement, N.Mex. 37.
meal as protein supplement for brood sows, Mich. 676.
mosaic causing pea streak, 496.
on bacterial wilt-infected soil, culture experiments, Iowa 35.

lfalfa—Continued.
pasture v. Sudan grass for dairy cows, Ohio 395.
pastures, tests for dairy cattle, S.Dak. 684.
phosphate requirements, N.Mex. 619.
phosphorus deficiency in, N.Dak. 475.
phosphorus in, Mich. 592.
planting tests, Iowa 35.
ıed clover, and sweetclover, relative value as soil-building crops, Iowa 14.
residual effects, [N.Y.]Cornell 450.
response to phosphorus, Mont. 616.
root nodule bacteria, relation to bacteriophage, 641.
root rots, N.Mex. 56.
roots, hemicellulose constituents in, 740.
roots, winter-injured, salts lost by, Wis. 475.
seed failures, causes, Utah 333.
seed, Montana grown, impurities found in, 625.
seed production, factors affecting, Wis. 497.
seed, shriveled, relation to *Lygus* bugs, 516.
silage, *see* Silage.
stands, methods of securing, Ohio 331.
stem nematode in Arizona, U.S.D.A. 496.
susceptibility to *Rhizoctonia solani*, 61.
treatment with gypsum, Idaho 616.
varieties, introduction, testing, and distribution, Mont. 616.
varieties, production tests, La. 474.
variety tests, Fla. 615; Idaho 616; Ind. 767; Iowa 35; N.Dak. 474; N.Mex. 36; Tenn. 767; Tex. 38; Wash. 38; Wyo. 39.
weevil problem, U.S.D.A. 655.
wilt- and cold-resistant, breeding, Wis 497.
wilt resistant varieties, Idaho 637.
winter killing, Colo. 207.
Algae—
absorption of radiation by, 181.
blue-green, nitrogen fixation, conditions favoring, 599.
fresh-water, of United States, 187.
soil, biology and taxonomy, 172.
Alkali soils of Iowa, character and management, Iowa 15.
Allantoin determination, improvements in micromethod, 296.
Almonds, pollination, 49.
Almshouses, county, inmates of, data, Mo. 129.
Alnus japonica, starch and fat reserves in, seasonal changes, 24.
Alorco for control of beetles, Tenn. 84.
Alsophila pometaria, *see* Canker worm, fall.
Alternaria—
citri, effect of gases on, Calif. 369.
in lemons, effects of storage and holding conditions, 802.
Alternaria—Continued.
solani, notes, 216.
sp., isolation from black knots, 68.
tenuis, notes, Conn.[New Haven] 356.
tomato n.comb., studies, 787.
Aluminum—
in biological tissues, studies, 743.
intravenously injected in dogs, storage, 884.
salts, toxicity to tobacco, 66.
sulfate and lime as repellent spray for Japanese beetle, 523.
sulfate, effect on potato scab, N.H. 474.
sulfate for color control of hydrangeas, 350.
Amaryllis—
insect and mite enemies, control, 376.
mosaic, Fla. 637.
Amblyomma spp. in Argentina, 85.
Amblypelta cocophaga—
cause of immature nut fall in coconut, 379.
notes, 81.
Ameba, mouth-inhabiting, apparent deep penetration and hystolytic action, Mich. 234.
Ameles, Mediterranean, parasites of oothecae, 818.
Amino acid, new essential, isolation and identification, 722.
Amino acids—
and peptides, complex salts of, 296.
and salts, interaction, 294.
basic, in human skin, relation to keratin, Conn.[New Haven] 293.
highly purified mixtures, feeding experiments, 722.
multivalent, studies, 5.
α-amino-β-hydroxy-n-butyric acids, synthesis, 722.
Ammonia—
determination, improvements in micromethod, 296.
formed by *Azotobacter*, origin and significance, 21.
Ammonium sulfate v. cyanamide for apples, Mo. 44.
Amylase activity, measurement, 297.
Amylase, alpha, determination, 160.
Anabasine sulfate, studies, N.J. 658.
Anaerobes, studies, 606.
Anaerobiosis, temporary, effect on sprouting of young potato tubers, 319.
Anagrus frequens, parasite of sugarcane leafhopper, Hawaii.Sugar Planters' 664.
Anaplasma ovis, effect of splenectomy, 543.
Anaplasmosis—
experimental transmission by biting flies, 840.
in cattle, P.R. 840.
transmission by three species of ticks in California, 254.
Anaplasmosis-like disease in Formosan swine, 544.
Anarsia lineatella, *see* Peach twig borer.
Anasa tristis, *see* Squash bug.

Anastatus—
ameleophagus, parasite of oothecae of mantids, morphology and biology, 818.
axiagasti, parasite of green coconut bug, 81.
picardi n.sp., parasite of oothecae of mantids, morphology and biology, 818.
Anastrepha—
fraterculus, *see* Fruitflies, West Indian.
longimacul, heavy infestation on Bombay mangoes, 806.
pallens from wild fruits in lower Rio Grande Valley of Texas, 522.
sp. in Peru, effect of low temperature, 383.
spp. at Key West, hosts and reaction to sprays, 522.
spp., Key West eradication project, 228.
Ancylostoma caninum, notes, 400.
Androstendione, activity on sexual organs of male rat, 193.
Anemia—
caused by deaminized casein, 889.
equine infectious, alterations in liver and kidneys in, 397.
equine infectious, complement-fixation with distilled water-spleen antigen, 545.
equine infectious, relation to so-called histiozytäre Zellen, 104.
from goat's milk, experimental studies, 428.
from goat's milk, use of iron and copper in curing, Wis. 535.
in monkeys due to vitamin-deficient diet, 426.
in suckling pigs, types of soil for prevention, Wis. 530.
nutritional, of animals, 397.
nutritional, relation to composition of home-grown foods, Fla. 717.
of pregnancy, hydremia as factor in, 724.
pernicious—
development of remedies for, 427
effect of hepatoflavine, 889.
gastric deficiency in, nature, 427.
of sheep and goats, 102.
produced by feeding young rats upon human, cow's, and goat's milk, comparison, 427.
Angel food cake, production, effect of altitude and other factors, Colo. 278.
Angiosperms, male gametophytes of, 187.
Anguillulina—
dipsaci, notes, U.S.D.A. 207.
dipsaci on alfalfa in Arizona, U.S.D.A. 496.
pratensis, notes, U.S.D.A. 207.
Animal—
breeding and nutrition, Me. 388.
byproducts, value in dairy ration, N.J. 684.
Animal—Continued.
diseases—*see also specific diseases*.
and parasites in Philippines, history, 253.
deficiency, relation to range soils, Colo. 238.
diagnoses, Ind. 840.
in Australia, 538.
in Bihar and Orissa, 538.
in Burma, 538.
in Canada, Ohio 397.
in England, prevention and treatment, 397.
in Jamaica, control, 538.
in Mysore, 538.
in New South Wales, 397.
in Queensland, 104.
in Rhodesia, 104.
in Straits Settlements, 104.
latent infections, 104.
tropical, manual, 102.
visible microbe, treatise, 690.
fats, *see* Fats.
husbandry, future changes from planned utilization of land, 527.
husbandry, prospective changes in eastern States, 527.
husbandry, responsibility in land use planning, 527.
parasites, *see* Parasites.
products, production-consumption balance, Mich. 559.
products, production, relation to population trends, 527.
tissues, iron determination in, modifications of bipyridine method, 743.
tissues, nutritive value, 877.
tissues, vitamin B_1 in, Wis. 564.
Animals—*see also* Cattle, Livestock, Mammals, Sheep, *etc.*
domestic—
early pregnancy in, diagnosis, 325.
ectoparasites in São Paulo, 840.
growth and development, Mo. 831.
in Puerto Rico, parasites, P.R. 840.
variations in rib number and asymmetry of thorax, 192.
farm, fat in rations, significance, 528.
farm, productivity, inheritance, 323.
insects affecting, Tex. 78.
laboratory, spontaneous virus diseases in, 540.
mineral requirements, U.S.D.A. 820.
phosphorus for, Mont. 530.
smaller soil, Berlese funnel for collecting, U.S.D.A. 655.
venomous, of Costa Rica, 805.
Anomala orientalis, *see* Asiatic beetle.
Anomis—
erosa as leaf defoliator of cotton, 518.
flava fimbriago on cotton in South Carolina, 226.
Anthelmintic efficiency, effect of size of dose, 399.

Anthonomus—
grandis, see Boll weevil.
pomorum, control, 807.
signatus, see Strawberry weevil.
Anthrax—
biological products used against, 538
symptomatic, *see* Blackleg.
vaccination experiments, 846.
Antibodies in plants, 463.
Antimony electrode, practical, for pH determination of soil, 19.
Antineuritic vitamin, *see* Vitamin B (B_1).
Antirachitic, *see* Rickets *and* Vitamin D.
Antiscorbutic, *see* Vitamin C.
Ants—
Argentine, distribution in United States and control, U.S.D.A. 673.
black, economic status in South India, 79.
intermediate host for *Raillietina echinobothrida*, 403.
leaf-cutting, ecology, 656.
leaf-cutting, sensitivity to poisonous gases, 656.
white, *see* Termites.
Antuitrin G, effect on food utilization and growth rate, 723.
Anuraphis roseus, see Apple aphid, rosy.
Apanteles tasmanica, parasite of apple leaf roller, 386.
Aphanomyces cuteiches, notes, N.J. 638.
Aphelenchoides fragariae—
notes, U.S.D.A. 636.
plants attacked by, U.S.D.A. 635.
Aphelinus mali, parasite of woolly apple aphid, 807.
Aphelopus typhlocybae, new parasite of white apple leafhopper, 655.
Aphid hunter, primer for, 812.
Aphididae, technic employed in work with, 812.
Aphids—
cloudy-veined, of importance in California, 380.
control, Mich. 658.
in Baluchistan and natural enemies, 79
measuring masses, graduated centrifuge tube for, U.S.D.A. 76.
of Florida, biology and control, Fla. 658.
woolly, *see* Apple aphid, woolly.
Aphis—
abbreviata and green peach aphid, comparison as vectors of potato diseases Me. 357.
gossypii, see Cotton aphid *and* Melon aphid.
medicaginis, see Cowpea aphid.
persicae, see Peach aphid, green.
pomi, see Apple aphids.
spiraecola, notes, Fla. 658.
Aphoebantus hirsutus, egg parasite of clear winged grasshopper, 515.
Apiaries, inspection, Conn.[New Haven] 657.
Apiculture, *see* Beekeeping.
Apion segnipes, damage to seeds of devil's shoestring, 660.
Aplanobacter stewarti—
bacteriophage, distribution, Ohio 357.
insect vectors, 522.
overwintering, 360; Iowa 360.
Aplasmosis, studies, Colo. 252.
Apparatus—
absorption tube, improved liquid, 585.
burette assembly for standard reducing solutions, 153.
dilatometer for plant materials, 607.
for collecting insects in the field, U.S.D.A. 76.
for counting pea seeds, U.S.D.A. 75.
for cutting corrugated paper, U.S.D.A. 76.
for cutting soil samples, U.S.D.A. 75.
for determination of photosynthetic and respiratory ratios, 754.
for magnesium determination, bromometric, 301.
for measuring intensity of atmospheric radiation, 161.
for measuring respiration and carbon fixation of plants, 182.
for recording humidity among leaves, U.S.D.A. 76.
for sand culture, 179.
for separating cotton root rot sclerotia from soil samples, 213.
for separating insects, U.S.D.A. 76.
for soil moisture determination, description, 586.
for soil washing, U.S.D.A. 77.
for spraying apples in laboratory, U.S.D.A. 76.
for starch determination, 303.
for testing dairy glassware, N.Y.State 101.
for treating insects with contact dusts, U.S.D.A. 76.
for uniform release of volatile chemicals, U.S.D.A. 76.
manometric manostat, description, 152.
oil gage, precision, description, 585.
slow-combustion pipet for gas analysis, 152.
tensiometers, description, 594.
used in identifying large numbers of leafhoppers, U.S.D.A. 77.
Apple—
aphid, rosy—
control, tar-lubricating oil spray tests, 665.
control with convergent ladybeetle, Conn.[New Haven] 657.
control with tar distillate emulsions, 375.
dinitro-o-cyclohexylphenol in petroleum oil for, tests, 225.
aphid, woolly—
causes of immunity to, 807.
effect on apple orchards, 788.
effect on death rate of trees in test orchard, 220.
parasite, notes, 807.

Apple—Continued.
aphids, control, Ohio 374.
bitter pit and related diseases, Wash 58.
bitter pit, studies, N.H. 497.
bitter rot, spraying for, Ohio 357.
black root rot, notes, 788.
black rot or frogeye disease, Ohio 357
blight, scarcity in Arkansas in 1936, U.S.D.A. 636.
blight studies, U.S.D.A. 636.
blossom weevil, control, 807.
blossoms, abscission, cause, 495.
blossoms, fire-blight infection, control. 787.
blossoms, low temperature injury, U.S.D.A. 636.
canker caused by *Monochaetia mali*, 220.
canker in southern Estonia, prevention. 503.
cankers, notes, Mo. 56.
capsid, spraying experiments, 807.
curculio, control, Wis. 513.
disease situation, review, 648.
diseases in western New York, 365.
diseases, notes, 799.
diseases, spray schedules for, 648.
diseases, spray tests for, Tenn. 789.
fire blight, spraying experiments for control, 495.
flea weevil, efficiency of fluorine for, 673.
flea weevil, studies, 656, 672, 673; Ohio 374.
flower, morphology, 48.
fruit moth injuries in mountain orchards of Switzerland, 374.
fruitfly, larval production and adult emergence, Me. 374.
gray mold, toxic action of cleaning solutions for spray residue removal, 801.
hairy root development, environmental factors in, 648.
insects, control in northern Illinois, 808.
insects, electric light traps for combating, Me. 374.
leaf-curling midge, notes, Mass. 512.
leaf roller, braconid parasite of, 386.
leafhopper parasitism, effect of orchard practices, 659.
leafhopper, white—
control, Mass. 512.
new parasite, 655.
parasitism by *Entomophthora*, 496, 664.
leaves, absorption of water by, 486.
leaves, CO_2 assimilation by, effect of sprays, R.I. 789.
leaves, lime-sulfur injury to, N.H. 497.
leaves, visible spray burn from lime-sulfur and copper sulfate solutions, R.I. 789.
maggot, bionomics and control, Iowa 77.
Apple—Continued.
maggot, breeding and control, Conn [New Haven] 657.
maggot control, Mass. 512.
maggot, notes, 671.
marmalade with and without a pine needle infusion as source of vitamin C, 571.
measles, etiology and histology, N.Mex. 56.
measles, studies, 503; Ohio 357.
orchard, McIntosh, fertilizer experiments, N.Y.State 202.
orchards, bearing, cultivation v. sod in, Mass. 483.
orchards, bearing, heavy mulching in, Mass. 487.
orchards, soil management systems, Iowa 44.
orchards, spray tests with lime-sulfur and bordeaux mixtures, R.I. 789.
pest control, new developments in Hudson Valley, 375.
progenies, inheritance of tree shape in, 487.
root activity, 20.
root necrosis, control, Iowa 55.
root systems, 48.
roots, growth, anatomy, and metabolism, effect of temperature, N.J. 627.
roots, growth, effect of systems of mulching and cultivation, Nebr. 197.
roots, normal and root rot infected, composition, Tex. 56.
rootstocks, notes, N.Y.State 48.
rust, control, Mass. 497.
rust, control in Hudson Valley, 803.
rust, increasingly serious losses from, 366.
rust, notes, Iowa 55.
rust on apple and red cedar, life history and control, 365.
rust, studies, U.S.D.A. 636.
sawfly, studies, 807.
scab and spray injury, 503.
scab and weather conditions in 1933, 366.
scab, control, 647; Iowa 55; Me. 357; Wis. 497.
scab control by sulfurs, Mich. 220; Ohio 357.
scab control, dusting for, 649.
scab control, newer modified spray formulas, 649.
scab control, spray tests, 649; N.J. 638.
scab control spraying results at La Fayette, Indiana, 649.
scab, copper-lime-arsenite mixtures for, Wis. 497.
scab, development, 366, 649.
scab, eradicant fungicides in relation to, 495.
scab fungus, time of maturity, effect of soil type, N.J. 638.
scab, spore discharge periods, 356.
scab studies, N.H. 497; U.S.D.A. 636.
seedlings, growing, new method, 781.

Apple—Continued.
sphinx, studies, Mass 512.
sprays, tests, Conn.[New Haven] 657.
sprays, zinc sulfate in, studies, Ill. 801.
spurs of different sizes, performance, N.J. 627.
stocks, propagation, Wash. 46.
storages, studies, Mass. 549.
thrips in South Australia, 378, 810.
tissues, winter-injured, anatomy, Me. 340.
tree borer, round-headed, bionomics and control, Iowa 77.
tree chlorosis, treatment, Idaho 637.
trees, carbohydrate storage in, Me. 44.
trees, daily photosynthesis from prebloom to leaf fall, 455.
trees, growth and reproduction, effect of cultural treatments, Ind. 778.
trees, growth, effect of winter injury, Me. 339.
trees, growth status, N.J. 627.
trees, improving the frame work by disbudding in nursery row, 627.
trees in orchard, effect of crown gall, hairy root, and woolly aphids, 788.
trees, length measurement, evaluation, 202.
trees, size at planting, relation to subsequent development, Me. 339.
trees, Stayman Winesap, composition, seasonal changes in, Ind. 778.
trees, Thornton test for potash in, 345.
trees, top- and double-working, Wis. 202.
trunk canker due to *Phytophthora cactorum*, Ind. 789.
twigs and leaves, respiration, effect of petroleum oils, 603.
woody tissue, starch polysaccharide from isolation and characterization, 149.
Apples—
and apricots, crossing experiments, S.Dak. 629.
Baldwin, a triploid variety, fertilization in, 323.
Beacon, characteristics, 48.
breeding, 487; Idaho 626; Iowa 44; Me. 339; Mo. 44; N.J. 627.
breeding for late blooming, Mo. 45.
cost of production, N.J. 711.
crab, *see* Crab apples.
cultivation v. heavy mulching for, Mass. 483.
cyanamide v. ammonium sulfate for, Mo. 45.
Delicious, pollination, Wash. 46.
effect of potash and lime, Mass. 483.
effect on intestinal putrefaction, Mass. 436.
female sex cells in, development, relation to fruit setting, Ohio 340.
fertilization, Idaho 626.
fertilizer and cover crop experiments, Mont. 626.
fertilizer experiments, 49.
fluorine spray residue removal, Wash. 782.
Apples—Continued.
gas emanating from, effect on potato growth, 463.
Golden Delicious, pollination, Mo. 45.
Gravenstein, color and maturity of fruit, factors affecting, 344.
Gravenstein, moldy core in, 67.
hardiness in, Mo. 45.
hardiness, relation to fertilizer applications, 49.
in storage, secondary scab infection, U.S.D.A. 55.
Jonathan, harvested, respiration cycle in, Iowa 44.
lead and arsenic on, accuracy of determination, 441.
lead residue removal by preharvest spraying, 781.
lead residue removal from, wetting agents for, 345.
maturing, chemical characteristics, Wash. 45.
McIntosh, pollination, Me. 340.
Michurin, varieties in Siberia, 344.
New England, cider making with, Mass. 436.
new stocks, particularly dwarfing, Iowa 44.
new, testing, Wis. 483.
nitrogen metabolism, biochemical studies, 314, 584.
Northern Spy, pollination, Mich. 781.
of England, treatise, 630.
outlook charts, U.S.D.A. 120.
persistence of toxicity of nicotine-bentonite on, 661.
pollination, Mo. 44; N.H. 483.
pollination and sterility, S.C. 45.
pollination studies with varieties, 781.
prices received by Washington growers, Wash. 868.
propagation on own roots, Iowa 44.
pruning, Ind. 778.
Richared, vitamin A in peel and flesh, Wash. 136.
self- and cross-pollinated, embryo development in, Mo. 45.
self-incompatibility in, relation to stage of flower development, Me 340.
shriveling, 628.
sodium nitrate for, Mass. 483.
softwood and root cuttings, propagation, Iowa 44.
spray coverage, determination, 160
spray residue removal from, 49, 340, 346; Idaho 626; Ind. 778; Mass. 482; Va. 488; Wash. 46.
spray schedule, use of nicotine in, 808.
spray schedules for, Ohio 201.
spraying, automatic, in laboratory, device for, U.S.D.A. 76.
spraying experiments, Conn.[New Haven] 356; Mo. 203; Pa. 345.
spraying for bronze beetle, 384.
spraying in Tennessee, high points in, 788.
stock and scion, interrelation, Mass. 483.

Apples—Continued.
storage, Ind. 778; Mass. 483; Me. 340.
tree and fruit responses in, Wash. 46.
triploid species, aposporic parthenogenesis in, 323.
uniform stocks for, growing, Iowa 44.
varieties, Iowa 44; N. H. 483.
varieties, prices received in San Juan County, N.Mex. 120.
varieties, response to storage temperatures, Iowa 44.
varieties, vitamins in, 280.
variety tests, La. 483; Wyo. 46.
vitamin C in, Wash. 136.
vitamin C in, relation to human welfare, 426.
washing solutions, Ind. 851.
winter injury, 496; U.S.D.A. 356.
Yellow Newtown, fruit thinning and biennial bearing on individual main leaders, 488.
York Imperial, yield relationships on terminal growths, 627.
Apricots—
and apples, crossing experiments, S.Dak. 629.
canned, prices received by canners, Calif. 712.
pollination, 49.
Aqueous humor of rachitic and normal rats, pH determination, microquinhydrone electrode for, 152.
Arceuthobium campylopodum, parasitism on *Pinus jeffreyi*, 508.
Architects, Government publications of interest to, U.S.D.A. 703.
Arduenna spp., notes, 400.
Areca brown rot of roots and stems, cause, 505.
Argo victorina, bionomics, 386.
Argyresthia conjugella, *see* Apple fruit moth.
Arkansas Station, notes, 142.
Armillaria mellea, effect of chloropicrin as soil fumigant, 638.
Armyworm—
Bertha, disease as check, 224.
Bertha, studies, N.Dak. 512.
southern, rearing, laboratory methods, U.S.D.A. 76.
Armyworms, emergency studies, Iowa 77.
Arsenic—
as present in shrimp v. arsenic trioxide, metabolism in rats, 884.
in sea food, compared with hazard from spray residue, 340.
on apples, accuracy of determination, 441.
trioxide as food poison for firebrat, 525.
Arsenical spray residue, *see* Spray residue *and specific fruits and vegetables*.
Arsenicals—*see also* Calcium arsenate *and* Lead arsenate.
effectiveness for destroying Japanese beetle larvae in soil, 523.
substitutes for, 376; Tex. 78.
Arthritis—
in a chick caused by *Salmonella pullorum*, 699.
in lambs, control, Mont. 691.
Artichokes—*see also* Jerusalem artichokes.
breeding, N.J. 616.
Arvelius albopunctatus, rare in the State, Tex. 78.
Ascariasis in calves, 846.
Ascaris—
lumbricoides, notes, 400.
sulla, cytoplasmic components in fertilization, 75.
suum, early developmental stages, U.S.D.A. 107.
vitulorum infestation of calves, 846.
Ascarops strongylina, early development stages, U.S.D.A. 107
Ascia rapae, *see* Cabbage worm, imported.
Ascochyta—
clematidina on *Clematis ligusticifolia*, U.S.D.A. 496.
pisi viciae in seeds of vetch, 625.
rabiei, studies, 362.
Ascomycetes, reproduction and inheritance in, 321.
Ascorbic acid—*see also* Vitamin C.
determination by titration, 572.
in urine, 741, 742, 744.
oxidation, copper and hemochromogens as catalysts for, 741.
reduced, in small amounts of blood, determination, 588.
silver nitrate reduction test for interfering action, 588.
Ash borer, control, N.Dak. 512.
Asiatic beetle—
as sugarcane pest, Hawaii.Sugar Planters' 84.
control, Conn.[New Haven] 374.
Asparagus—
animal pests, control, 656.
beetles, notes, 806.
breeding, N.J. 627.
bunches, tying, use of rubber bands for, S.C. 45.
cost of production, N.J. 711.
culture, Iowa 44; Mass. 483.
culture experiments, Ga.Coastal Plain 197.
culture in south Louisiana, La. 341.
fern rust, Fla. 636.
fertilizer experiments, Ga.Coastal Plain 197; Mass. 483; Tex. 45.
iodine in, Okla. 131.
plats, uniformity trials, 627.
precooling and shipping, Calif. 483.
value of calcium cyanamide for, Tenn. 779.
variety tests, Ga.Coastal Plain 197.
yields and quality, effect of mulching, Nebr. 197.
Aspergillus—
fuscus for measurement of soil fertility, Wis. 445.

Aspergillus—Continued.
niger, assimilation of phosphorus by, 173.
niger, formation of fatty acids from glucose by, 294.
niger, growth and development in synthetic nutrient solutions, 462.
niger, growth, effects of heavy metals, 761.
niger, use in testing potash availability, 300.
parasiticus, peptidase system, 639.
spp., vitamin B complex in, 566.
Aspidiotus—
lataniae on avocado, life history and control, 380.
orientalis attacking lac host trees, 808.
perniciosus, *see* San Jose scale.
Assimilation, theory of, 461.
Association of Official Seed Analysts of North America, proceedings, 625.
Aster wilt, studies, Ind. 789.
Asterococcus canis n.sp., description, 848.
Asteromyia phragmites, new in Ohio, 381.
Asters—
China, growth and flowering, effects of day length and light intensity, 349.
reduction of daylight period on, 349.
Asthma in children, analysis of three hundred cases, 428.
Asynonychus godmani, *see* Rose beetle, Fuller's.
Atheria variegata, notes, Conn.[New Haven] 657.
Athous, account of genus, Me. 817.
Atmospheric—*see also* Air.
circulation and precipitation in Near East, 162.
moisture, *see* Humidity.
tides, lunar, over Canada, 162.
Atta sexdens—
ecology, 656.
sensitivity to poisonous gases, 656.
Attelabidae from India, new, 79.
Aujeszky's disease, *see* Paralysis, infectious bulbar.
Autographa brassicae, *see* Cabbage looper.
Autopsies in connection with avian pathology, Mich. 691.
Autoserica castanea, biology and control, 522.
Auximone problem, summary, 318.
Auxin role in intumescences, cell outgrowth and leaf fall, 456.
Auxin-a and heteroauxin, different action, 318.
Avitaminosis—*see also different vitamins*.
A in swine, Mo. 87.
Avocado—
diseases, cause and control, 368.
leaves, accumulations of salts in tips, relation to tipburn, 368.
ring-neck, relation to chlorine in, 651.
stem, anatomy, effects of sun blotch, 368.
Avocados—
composition, nutritive value, and use, Hawaii 879.
culture, Fla. 626.
Avocados—Continued.
Fuerte, bearing behavior, 50.
sterol content, Hawaii 415.
Axolotls—
metamorphosis, effect of pharmacological products, 326.
thyreotropic hormone and metamorphosis in, 326.
Azaleas—
growth, relation to soil reaction, 51.
winter forcing, R.I. 779.
Azoproteins, notes, 293.
Azotobacter—
ammonia formed by, origin and significance, 21.
ammonia production by, relation to mechanism of nitrogen fixation, 600.
chroococcum, nitrogen distribution, 607.
chroococcum, sulfur requirements, 174.
nitrogen fixation and amide utilization, specific intermediates in, 600.
occurrence and activities in Iowa soils, Iowa 15.
Babesiella, effect of splenectomy, 543.
Baby beef, *see* Cattle, baby beef.
Bacillus—
abortus, *see* Abortion *and Brucella abortus*.
alvei strains, description, 385.
amylovorus in insects, persistence, 639.
amylovorus, notes, 647.
amylovorus, scarcity in Arkansas in 1936, U.S.D.A. 636.
as bacterial generic name, fixing type species and standard culture, 464.
haemoglobinophilus-coryza-gallinarum, proposed name, 110.
larvae spores in honey contaminated with American foulbrood, 673.
megatherium, growth, relation to oxidation-reduction potential, 187.
pectinophorae, notes, 230.
pyogenes in dairy cows, peculiar selective site, 542.
radicicola, *see* Legumes, inoculation, *and* Nodule bacteria.
suipestifer, notes, 104.
typhi murium cultivated in rye grain, effect on rodents, 694.
Bacon—
marketing data of Canada, 276.
quality, production from hogs on irrigated alfalfa pasture and cereal grains, Mont. 677.
Bacteria—
aciduric, and certain food elements, relation to tooth decay, 733.
anaerobic, *see* Anaerobes.
and fungal spores, viability in canopic jar sealed over 3,000 years, 353.
effect of high frequency electric current, N.J. 658.
genetical studies, 761.
in milk, soil, etc., *see* Milk, Soil, *etc.*
nitrifying, in water supplies, 267.
photosynthesis, 181.
phytopathogenic, isolation methods, 498.

Bacteria—Continued.
production and distribution for legumes, Mo. 15.
Bacterial phytopathogens, green fluorescent, comparative studies, 208.
Bacteriophage, relation to root nodule bacteria of alfalfa, 641.
Bacterium—
abortus, see Abortion *and Brucella abortus.*
aerogenes, effect of bile and bile salts, Mass. 436.
aertrycke endotoxin, production, detoxication, and use of antigenic properties, 539.
angulatum, Physalis subglabrata as natural host, 646.
auxinophilum n.sp., notes, 186.
citri, see Citrus canker.
gallinarum and *B. pullorum,* differentiation by means of bacteriophage, 259
glycineum, notes, 364.
pruni, notes, 495.
pullorum—see also Salmonella pullorum and Pullorum disease.
and *B. gallinarum,* differentiation by means of bacteriophage, 259.
radicicola, see Legumes, inoculation, *and* Nodule bacteria.
rhizogenes, development, environmental factors in, 648.
sojae, notes, 364.
solanacearum, notes, 207, 494; Fla. 636.
status as generic term, 606.
tabacum, notes, 219.
translucens v. *undulosum,* cause of wheat black chaff, 211.
welchii, see Clostridium welchii.
Bactrocera cucurbitae, see Melon fly.
Bagasse and paper mulches, effect, 19.
Bagworm in New Haven, Conn.[New Haven] 657.
Bagworms, control, N.J. 380.
Bahia grass—
grazing value, Fla. 235.
grown in lysimeters, cutting experiments, Fla. 40.
Bait solutions for oriental fruit and codling moths, 376.
Balsam fir heart rot in Lake States, Minn. 71.
Bamboo, culture, improvement, and utilization, P.R. 778.
Banana—
black tip, notes, 208.
diseases in British Guiana, 357.
leaves, photosynthetic activity, 314.
Bananas—
as source of iron for hemoglobin formation, 725.
composition, nutritive value, and use, Hawaii 879.
dietary use for weight control, Mass. 563.
dietary uses in health and disease, 566.
effect of frost of January 1934 in India, 12.
Bananas—Continued.
feeding value for pigs, Hawaii 388, 529.
insects affecting, 806.
Bankruptcies among farmers and debt compositions and extensions, U.S.D.A. 710.
Barathra configurata, see Armyworm, Bertha.
Barberry eradication—*see also* Wheat stem rust.
Mont. 637; N.Dak. 497.
Baricide, insecticidal value, 671.
Barium carbonate, effect on Mexican bean beetle, 671.
Bark beetles—
and host plants, 656.
associated with blue staining fungi, 509.
outbreaks, control, 384.
Barley—
blighted v. bright, for fattening steers, N.Dak. 529.
breeding, Idaho 616; Iowa 35; Mo. 36; S.Dak. 617; Tenn. 767; Tex. 38; Wash. 38.
covered smut, control, 499.
culture experiments, Wyo. 39.
diseases, control, Wis. 497.
feeding to finishing yearling steers, Mont. 676.
feeding value, Colo. 531.
grinding, need for uniformity when hand-fed to pigs, Wis. 530.
ground, v. dried molasses beet pulp, Wyo. 99.
increased amount, and less alfalfa and silage, effect on steers, N.Dak. 529.
inheritance studies, Wash. 38.
kerosene and petroleum oils in, distribution, 62.
linkage studies, Colo. 194.
loose smut, inoculation method, 495, 639.
malt amylases, concentration and properties, 150.
Missouri Early Beardless, breeding, Mo 36.
outlook charts, U.S.D.A. 120.
response to phosphorus, Mont. 616.
seed, germination, effect of seed-borne pathogens and of seed disinfectants, 625.
seed, State certified, N.J. 339.
seedling diseases, N.Dak. 497.
seedlings, respiration, effect of petroleum oils, 603.
seeds, effect of organic mercury dusts, Iowa 55.
smut, control, U.S.D.A. 639.
sowing on bluegrass and Bermuda sod, Tenn. 767.
stripe rust, Idaho 637.
susceptibility to *Rhizoctonia solani,* 61.
Trebi v. common, feeding value, N.Dak. 529.
varieties, acre yields, Ind. 767.
varieties, introduction, testing, and distribution, Mont. 616.

Barley—Continued.
varieties, new scab-resistant for Iowa, Iowa 55.
varieties, phosphorus deficiency in, N.Dak. 474.
varieties, responses to leaf rust of wheat, 641.
variety tests, Alaska Col. 766; Idaho 616; Iowa 35; Mo. 36; N.Dak. 474; N.J. 616; N.Mex. 36; Nebr. 195; Tex. 38; Utah 334; Wash. 38; Wyo. 39.
yields, Ind. 767.
Barns—
dairy, ventilation, Idaho 701.
open-shed type, for dairy cattle, Mont. 684.
wind-proof gothic, plans, 266.
Bartlett, J. M., tribute to, Me. 431.
Bartonella, effect of splenectomy, 543.
Base exchange, studies, N.J. 592.
Basisporium gallarum, pathogenicity to corn, Iowa 55.
Basket—
stock in Indiana, marketing timber for, Ind. 787.
veneer and handle stock, marketing, Ind. 784.
Bats—
infected with *Trypanosoma equiperdum*, effect of low body temperatures, 541.
vampire, transmission of *Trypanosoma hippicum* by, 399.
Bauhinia purpurescens, new host of *Phymatotrichum omnivorum*, Tex. 56.
Bean—
bacterial blights, Fla. 637.
bacterial blights, resistance to, Ohio 357.
beetle, Mexican—
barium carbonate for, 671.
control by new and improved form of cryolite, Tenn. 83.
correct name, 224.
distribution and prevalence, relation to evaporation rates, Ohio 443.
host larvae and adult parasites, shipping by air mail, U.S.D.A. 75.
studies, 374; S.C. 78.
blight of limas, Fla. 637.
curly top, Idaho 637.
disease, zinc deficiency, Fla. 637.
diseases in Colorado, U.S.D.A. 207.
diseases in Copiah County, Mississippi, U.S.D.A. 636.
diseases, studies, S.C. 56.
diseases, virus, Mont. 638.
leafhopper, control, Tex. 78.
mosaic—
physiology, N.Y.State 63.
resistant varieties, Idaho 637; Wis. 497.
symptoms of Refugee variety, N.Y.State 64.
transmission, N.Y.State 63.
Bean—Continued.
mosaic—continued.
virus, inheritance of resistance to, 793.
plants, respiration, effect of petroleum oils, 603.
production, economics of, Mich. 864.
root knot, relation to nematodes, Fla. 637.
root rot, Idaho 637.

seed selection for disease resistance, Mo. 45.
soil and cultural requirements, [N.Y.] Cornell 46.
variety tests, Ohio 340.
vitamin C in, N.Y.State 728.
webworm, notes, 374.
yellows resistance, two types, 494.
yellows resistant varieties, Wis. 497.
yield in Ohio, factors affecting, Ohio 484.
Cabbageworm, imported—
insecticides for, tests, 667.
rearing, laboratory methods, U.S.D.A. 76
Cabbageworms—
control by sprays and dusts, Ohio 374.
effect of Alorco, Tenn. 84.
on cole crops, arsenical substitutes for, Me. 374.
Cacao—
black pod and other diseases, 207.
diseases, 208.
diseases in British Guiana, 357.
sudden death disease due to fluctuations in rainfall, 208.
Cacoecia—
argyrospila, *see* Fruit tree leaf roller.
murinana outbreak in lower Austria, 657.
Cactus—
pricklypear, control, Tex. 38.
spineless, yields and feeding value, Tex. 38.
Caddisflies, studies, Wash. 79.
Cadelle, predator of Tribolium, U.S.D.A. 524.
Cadmium coatings on steel, corrosion-protective value, 115.
Cage construction, plaster of paris and molding plaster in, U.S.D.A. 75.
Cage, experimental plot, construction, U.S.D.A. 76.
Cake—
angel food, making, effect of altitude and other factors, 878.
making, quality of eggs for, measuring, 564.
Calcium—*See also* Lime.
absorption by soils, Tenn. 747.
analysis, digesting biological materials for, 156.

Calcium—Continued.
arsenate—
effect on rice, 472.
in codling moth control, present status, 375.
place in spray program, N.Y.State 80.
toxicity to rice on flooded soils, 772.
toxicity, effect of soil colloids, 472.
toxicity to millet, effect of colloidal soil materials, 448.
arsenates, commercial, safeness to foliage, determination, N.Y.State 8.
chloride, effect on micro-organisms, Colo. 168.
combinations, availability to poultry, Wis. 530.
content of soils, relation to acidity, Mo. 15.
cyanamide—
and decomposition products, physiological studies, Ohio 482.
granular form, effect on nematodes, 654.
use in orchards, Mich. 203.
deficiency, effects on peas, 25.
determination in biological material, improved methods, 301.
determination in soils, Colo. 540.
distribution between skeleton and soft tissues, 89.
effect on colloids, 453.
in blood serum, colorimetric determination, Colo. 540.
in cheese, error in data reported, 277.
in cotton at various stages, 472.
in grasses and herbage, Colo. 540.
intake levels, effect on hatchability and eggshell formation, R.I. 824.
involvement in magnesium deficiency, 881.
metabolism of laying hens, 825.
milk forms as source, relative economy, 717.
needs of preschool children, 882.
of diet, effects of increasing, 881.
relation to growth, nodulation, and composition of soybeans, Mo. 42.
replaceable, effect on index of friability of soil, 175.
requirements of cows, Vt. 834.
requirements of lambs, Ohio 389.
requirements of pigs, determination, Ohio 389.
role in determining reproductive success, 677.
salts, availability for growth and bone formation in chicks, 392.
sulfate, *see* Gypsum.
transport in cotton plant, 459.
Calcutta sore of cattle, etiology, 104.
Calf diphtheria, Wyo. 103.
Caliciopsis pinea—
morphology and development, 320.
pathogenicity and cultural experiments, 803.
California Station, notes, 287.
Caliroa aethiops, see Rose sawfly.
Calliphora erythrocephala—
laboratory breeding, 806.
observations and experiments on during first day after emergence, 816.
temperature tolerance in, 383.
vector of encephalitis, 663.
Callosobruchus chinensis, see Cowpea weevil.
Calomel for root maggot control, N.Y.State 228.
Calomycterus setarius, infestations, 232; Conn.[New Haven] 657.

Capons—
comb and spur development, effect of ovarian grafts and folliculin benzoate, 330.
plumage response to oestrone injection, variation, 765.
Carambola, composition, nutritive value, and use, Hawaii 879.
Carbohydrates—
formation in sugarcane and other plants, Hawaii.Sugar Planters' 26.
of potato leaves, diurnal changes, effect of potassium chloride, 316.
Carbon—
accumulation or depletion in soils under different treatment, Mo. 15.
dioxide determination, absorption and titration flask for, 439.
dioxide, effect on pH and nitrogen fractions of sugar beets, 4.
fixation and respiration of plants, apparatus for measuring, 182.
monoxide absorption with reduced hematin and pyridine hemochromogen, 295.
monoxide poisoning in chickens, 827.
organic, in soils, effect of crops and cropping systems, 476.
Carborundum as an abrasive in plant virus inoculations, 790.
Carcinoma, genital, prolans of urine of woman with, 325.
Cardamom, new disease in South India, 79.
Cardiophorus, account of genus, Me. 817.
Carnation blight and wilt, control, 652.
Carnations—
fertilizers for, Ohio 340.
perpetual flowering, wilt, stem rot, and die-back, 370.
Carotene—
added to butterfat, absorption of light by, Tex. 98.
and vitamin A, 885.
Carotene—Continued.
color, and vitamin A in butter, relation, Ind. 831.
fed in butterfat and cottonseed oil, relative vitamin A potency, 726.
fed in butterfat, vitamin A potency, Ind. 830.
for coloring butter, Ohio 395.
in alfalfa hay and meal, factors affecting, 678.
in papayas, Hawaii 415.
in prophylactic pediatrics, 430.
synthesis from carotenoids in plants, Wis. 564.
Carotenoid formation in tomatoes, effect of light, [N.Y.]Cornell 629.
Carpenter ant, black, notes, Conn [New Haven] 658.
Carpenter worm, control, N.Dak. 512.
Carpet grass—
grazing value, Fla. 235.
Mineral content, effect of fertilizers, S.C. 37.
pasture, fertilization, 473; S.C. 37.
Carpocapsa pomonella, *see* Codling moth.
Carpophilus—
hemipterus, *see* Fruit beetle, dried.
spp. in pineapple fields, biological studies, 384.
Carrot—
leaf blight, notes, Tex. 57.
roots, structure, effect of culture, Nebr. 197.
seeds, storage, 46.
Carrots—
growth and color, environmental factors in, [N.Y.]Cornell 485.
growth, optimum levels of soil nitrates, R.I. 779.
iodine in, 567; Okla. 131.
magnesium requirements, Va.Truck 779.
susceptibility to *Rhizoctonia solani*, 61.
Casein—
addition to pituitary synergist, effect, 328.
deaminized, anemia caused by, 889.
utilization by rats, 280.
v. lactalbumin in vitro, enzymic digestion, 722.
Cassava meal—
and coconut oil cake, feeding value, Hawaii 395, 534.
feeding value for pigs, Hawaii 388.
for fattening swine, Hawaii 529.
Cassia occidentalis, poisonous to livestock in Florida, Fla. 690.
Cassia spp., mycorrhizal infection in, 71.
Cassida beetles, injurious to sugar beets, 374.
Castanea pubinervis, starch and fat reserves in, seasonal changes, 24.
Castor oil plants grown by sheet-culture technic, effect of variation in rate of water flow, 456.
Castor-bean, insect enemies in Madras Province, control, 80.

Castration—
atrophy and theelin, 34.
in rats, relation to vitamin A deficiency, 569.
Cataract—
in rats on diets deficient in vitamin B_2, 886.
nutritional, cause and control, Mass. 563.
nutritional factors in, 727.
Catarrh, malignant bovine, transmission experiments, 695.
Cats, spontaneous virus diseases in, 540.
Cattail borer, notes, Conn. [New Haven] 657.
Cattle—*see also* Calves, Cows, Heifers, Livestock, *and* Steers.
baby beef—
amount of grain for most economical finishing, Tenn. 820.
fattening, preparation of milo grain for, Tex. 88.
production, rations for, S.Dak. 677.
beef, breeding, 230.
beef, experiments with, Mo. 86.
beef, feeding experiments, Colo. 530; Mont. 676; Nebr. 238.
beef, growth and breeding qualities, effect of phosphorus and calcium, S.C. 87.
beef, outlook charts, U.S.D.A. 120.
beef, production, Ga.Coastal Plain 238.
beef, silage v. shocked corn for, Mich. 676.
beef, wintering, flaxseed husks v. cottonseed hulls for, S.C. 87.
breeding efficiency, value to dairymen, Idaho 683.
dairy—*see also* Cows.
all-year pasturing with and without concentrates, Tenn. 536.
breeding, correction factors and germ plasm, 527.
breeding for high production, N.Dak. 535.
feeding experiments, Hawaii, 534.
growth studies, Nebr. 243.
hardy strain, development by crossing, Alaska Col. 819.
nutritional deficiency diseases, Me. 388.
persistency and inheritance of milk and fat production, Iowa 97.
supernumerary teats in, 833.
weights, estimating from heart-girth measurements, U.S.D.A. 686.
winter grazing crops for, S.C. 98
disease—*see also specific diseases.*
chronic, due to timber milk vetch, Colo. 539.
new, Tex. 103.
dual-purpose and native, mineral intake, Fla. 675.
fattening, tankage for, Ind. 819.
feed production in rotations for sugarcane, 529.
Cattle—Continued.
feeder, three classes, efficiency and profitableness, Ohio 239.
finishing, cost, effect of age, 528.
finishing without corn, Ind. 819.
flies on, dusts for control, 521.
growth and milk production, effect of types and amounts of protein and minerals, Wis. 535.
Guernsey, pigmentation in skin and milk, N.J. 684.
heat production, estimation, 821.
herds, abortion-infected, maximum titer studies in, Mo. 102.
Hereford yearlings, native v. grade, meat quality, 529.
Holstein, inbreeding and outcrossing for high milk and fat production N.J. 684.
Holstein-Friesian, genetic history in United States, 324.
hydatidiform mole in, 397.
improvement of production by breeding, Wyo. 99.
Jersey, lethal gene in, 32.
kinky tail in, 542.
loin disease, Tex. 102.
marketing data of Canada, 276.
mineral requirements, Tex. 88.
native, grading up with purebred bulls, Fla. 675.
native Indian, half-bred cows, and buffalos, milk and butterfat production, 833.
of different ages and body weights, horizontal walking, energy expense, Mo. 87.
performance in shed barns v. dairy barns, N.Dak. 535.
plague, *see* Rinderpest.
poisoning, *see* Livestock poisoning, Plants, poisonous, *and specific plants.*
price, Oklahoma farm v. Kansas City and Chicago price of stockers and feeders, Okla. 709.
purebred Holstein-Friesian, breeding for high milk and butterfat production, Wash. 98.
purebred Shorthorn herd, bred for twenty years without new blood, 608.
range, experiments with, N.Mex. 87.
range, oak poisoning in, 842.
range, phosphorus deficiency, Colo. 238.
rations, deficiencies in feeds used in, Fla. 683.
shy breeding, treatment with pituitary hormone, Wis. 466.
skin defect in, inheritance, 32.
sterility in, causes, 194.
sweetclover disease of, N.Dak. 537.
tick fever, control in Jamaica, 538.
ticks, *see* Ticks.
twins, two-egg, with like characteristics, 192.
variations in rib number and asymmetry of thorax, 192.

Cattle—Continued.
vertebral column in, inheritance of irregularities, 467.
vitamin A in nutrition, 528.
wintering on range and in feed lot, rations for, Mont. 676.
yearlings, fattening, Ohio 239.
Cauliflower—
disease due to joint action of *Phytomonas* and *Alternaria*, 207.
soil and cultural and fertilizer requirements, [N.Y.]Cornell 46.
variety tests, Ohio 340.
Cavity fillers, Ind. 806.
Cedar rust, *see* Apple rust.
Cedars in Maine, rusts on, U.S.D.A. 636.
Celama sorghiella, *see* Sorghum webworm.
Celery—
diseases, control, 208.
early blight, Fla. 637.
early blight, control by copper dusts, Mich. 214.
fertilizer needs, Fla. 626.
pink rot, U.S.D.A. 356.
seed, production, N.Mex. 45.
storage, Mass. 483.
Verticillium affecting, U.S.D.A. 356.
Cell—
division and growth hormone, 185.
substances, granule-forming, pass through living plasmalemma, 458.
Cells—*see also* Plant cells.
elongation and electrical properties of cell wall, 458.
living, electric potential at flux equilibrium, 28.
stretching, mechanism on basis of micellar theory, 184.
Cellular pathology, studies in, 367.
Cellulose—
in plants, analysis, 742.
materials, colloid chemistry, U.S.D.A. 740.
role in nitrogen preservation in soils and composts, 600.
Cement mortars, speed portland and blended, physical properties, 263.
Cements, natural and pozzolanic blended, bibliography, 262.
Centipede grasses, grazing value, Fla. 235.
Centipede, house, notes, Conn.[New Haven] 658.
Centrifugal force, nomogram for, 6.
Cephaleuros parasiticus, cause of tea red rust, 223.
Cephalobus elongatus—
on alfalfa in Arizona, U.S.D.A. 496.
on potato and iris, U.S.D.A. 207.
Cephalosporium—
acremonium, entry into growing corn ears, 495.
relation to Dayton elm disease, 496.
Cephalothecium roseum—
antagonistic action toward *Helminthosporium sativum*, 59.
notes, 68.
Ceracris kiangsu, outbreaks in China, 810.
Cerambyx cerdo, life history, economic importance, and control, 656.
Ceratostomella—
fimbriata, notes, 372.
ips, cause of blue stain of sapwood, 509.
piceaperda n.sp., description, 509.
pseudotsugae n.sp., description, 509.
ulmi in tissues of elm, growth and distribution, 494.
ulmi, life history, 653.
ulmi, notes, 371.
Ceratoteleia marlatti, notes, S.Dak. 81.
Cercaria spp., cause of dermatitis, 805.
Cercospora—
apii, destructive epidemic on celery, Mich. 214.
beticola on sugar beets, epidemiology, relation to infested soil, 495.
spp., host range and intertransmissibility, Iowa 55.
staticis, notes, Tex. 57.
Cereal—
diets, effect on composition of body fat of rat, 723.
disease resistance, nature, 211.
diseases, 208.
diseases in Delaware, 356.
diseases in New South Wales, 358.
diseases, seed treatment for, Idaho 637.
hay, nutritive value, Wash. 88.
laboratory methods, 302.
root rot diseases, control, 58, 59.
rusts—*see also* Rusts *and specific hosts*.
control in Italy, 358.
micro-organisms antibiotic or pathogenic to, 495.
seed treatment, *see* Seed treatment.
seeds, length of dormant period, 776.
smuts—*see also* Grain smuts, Smuts, *and specific hosts*.
control by seed treatment, 499.
stem rust epidemic of 1935 in Nebraska, U.S.D.A. 359.
stem rust, overwintering, U.S.D.A. 356.
Cereals—*see also* Grain *and specific grains*.
and grasses as companion crops, competition, Wash. 38.
residual effects of legumes, [N.Y.]Cornell 450.
yields in rotation with alfalfa and red clover, Ohio 331.
Ceresa bubalus, *see* Buffalo treehoppers.
Ceroplastes floridensis, *see* Wax scale, Florida.
Cestodes, new species from Trinidad deer, 655.
Ceutorhynchus macula alba, biology and control in Hungary, 385.
Chaetocnema pulicaria, *see* Corn flea beetle.
Chaetodacus—
cucurbitae, supercooling death, 809.
tryoni, control with white oil-nicotine sulfate spray, 816.
Chamizn, growth and germination, N.Mex. 37.

Cheese—
American, packaging, Wis. 249.
Blue, making, mold powders for, Iowa 97.
calcium and phosphorus in, error in data reported, 277.
Cheddar, bitter flavor in, 839.
Cheddar, bitterness in, control, Wis. 535.
Cheddar, effect of cooling on quality of milk for, N.Y.State 100.
Cheddar, use of pH determination in predicting acid development, 839.
consumer preferences for, Wis. 127.
cottage, making on farm, Ohio 689.
cottage, manufacture, use of dehydrated milk in, Mo. 98.
cream, acidity in, Wis. 535.
cream, gas defect in, yeasts causing, Wis 535.
making in France, N.Y.State 689.
meal from cheese trimmings for poultry and hogs, Wis. 530.
new project started, N.Y.State 250.
processed, emulsifiers for, Wis. 535.
retail margins in independent stores, Wis. 555.
sage, manufacture, N.Y.State 101.
Swiss-type, manufacture, Iowa 97.
Trappist-type, manufacture, N.Y.State 249.
vitamin D in, 426.
Chemistry—
agricultural, importance of enzyme analysis in, 11.
agricultural, results of work in, treatise, 580.
colloid, *see* Colloid chemistry.
inorganic, Gmelin's handbook, 581.
Chenopodium—
experiment in worming pigs, S.Dak. 691.
pharmaceutical studies, S.Dak. 691.
Cherries—
cracking, factors in, Idaho 626.
doubling, 489.
effect of adverse climate on size of fruits, 489.
fertilization, Idaho 626.
fertilizer and cover crop experiments, Mont. 626.
frozen, use in ice cream, 690.
improvement, breeding for, N.Y.State 203.
Maraschino, gain in popularity, N.Y. State 203.
root system, 48.
set, factors affecting, Wis. 483.
sour, variety tests, Wyo. 46.
spray schedules for, Ohio 201.
sweet, variety tests, N.Mex. 45.
Cherry—
aphid, black, life history, habits, and control, Mont. 513.
black knot, studies, 68.
canker, notes, Iowa 55; Mo. 56.
casebearer, control, Wis. 513.
fruit, growth study, 346.
Cherry—Continued.
fruitfly, black, life history, habits, and control, Mont. 513.
fruitfly, unsuccessful eradication, Idaho 658.
leaf curl and root injury, 650.
leaf spot, bordeaux mixture for control, Wis. 497.
leaf spot, control, 366, 800.
leaf spot, epidemiology and control, 495.
leaves, absorption of water by, 486.
mottle leaf, history and symptoms, 503.
orchards, Montmorency, yields, Mich. 782.
rootstocks, notes, N.Y.State 48.
seed, preplanting treatment, 784.
Chestnut blight, Conn.[New Haven] 356.
Chick embryos from hens fed different protein levels, growth, 390.
Chicken—
and turkey hybrids, experimental production, 611.
cookery, problems, 718.
Chickens—*see also* Chicks, Fowls, Hens, Poultry, *and* Pullets.
broiler production, Md. 242, 412; N.C. 533.
broiler, rations, soybean oil meal in, Ind. 820.
broiler, rations, wheat and oats in, Ind. 819.
broilers and fryers, fattening rations, Fla. 676.
refrigerated, freezer burn on, 683.
winter broilers, production, electric v. coal brooders for, Mich. 676.
Chicks—
affected with pullorum disease, effect of feeding colon organisms and dried whey, Fla. 690.
amino acid content, relation to diet and incidence of chondrodystrophy, 680.
battery brooder, slipped tendons in, wheat gray shorts for prevention, Tex. 682.
brooding, heat requirements for, N.H. 549.
congenital tremor in, Minn. 611.
effect of flavine, 681.
effect of sodium bicarbonate, 828.
electric brooding, Ind. 851.
embryo and baby, vitamin A reserve, 681.
feeding, Wis. 242.
feeding value of kelp for, 391.
growth and sex differences, effect of calcification, 827.
growth, effect of sterilizing ration with steam, Wis. 530.
leg disorders in, effect of feed, Tex. 88.
lime and phosphoric acid requirements, Tex. 88.
management tests, 829; Ohio 389.
newly hatched, operative removal of yolks from, 394.
newly hatched, thyroid weight and sex in, 242.

Chicks—Continued.
nitrogen, calcium, and phosphorus utilization, factors in, Nebr. 680.
plumage, relation to growth and sexual maturity, 613.
protein requirements, 94.
rachitic, calcification in, effect of seasonal variation and sex, 827.
raised on vitamin C-deficient ration, vitamin C in organs, 729.
rearing, confinement v. range, 529; Fla. 675.
reduction of protein in rations, Ind. 819.
sexing, directions for, 532.
sexing, economic aspects, 529.
sexing when day old, success in, 531.
simplified diets for, Mo. 87.
slipped tendon in, effect of single grains, 828.
starting rations, 529; S.C. 87.
vitamin A content of livers, 390.
vitamin A requirements, Ohio 389.
vitamin G requirements, 95; Ohio 389.
when grown in absence of sunlight, vitamin D requirements, Tex. 95.
Chickweeds in fine turf grasses, herbicide for, Mass. 474.
Children—*see also* Boys *and* Girls.
asthma in, analysis of three hundred cases, 428.
feeding problems, relation to food aversions, 280.
Glasgow school, health of, 420.
in Maine, nutrition, Me. 420.
preschool, calcium and phosphorus needs, 882.
preschool, iron metabolism in, 725.
response to iron and copper combined as compared with iron alone, Wis. 564.
rural school, vitamins in winter diet, 726.
Children's wardrobes, study, 575.
Chili—
ground, value in laying ration, N.Mex. 87.
leaf curl, cause, 81.
pepper, vitamin A and vitamin C in, 136.
thrips, biology and control, 81.
Chilies—*see also* Peppers.
culture in Madura District, India, 79.
Chilo simplex, see Rice borer, Asiatic.
Chimneys, temperature stresses in, 266.
Chinch bug—
abundance and wheat yield, Ohio 374.
bionomics and control, Iowa 77.
control, Mo. 77.
false, control, Tex. 78.
feeding on different sorghum and corn varieties, effect on biology, 378.
freezing temperatures of, 512.
hairy, as lawn pest, Conn.[New Haven] 657.
hairy, biology and control, 516.
studies, Nebr. 224.
Chloramine in water supplies, estimation, 157.
Chloramine-T products, germicidal potency, evaluation, 687.
Chlorella, kinetics of photosynthesis in, 181.
Chlorine—
compounds, germicidal potency, evaluation, 687.
disinfection of eating utensils, 417.
in organic compounds, determination, 589.
Chlorophyll—
behavior in inheritance, 181.
development, role of magnesium in, Va. Truck 779.
disks, flattened, as structural assimilation units of chloroplasts, 755.
granules, possible structure in the plastid, 458.
Chlorophyllometry, 743.
Chlorophylls, fluorescence and photodecomposition in presence of air and gases, 181.
Chloropicrin—
fungicidal value as soil fumigant, 638.
separator, device for separating insects from host material, U.S.D.A. 76.
Chloroplasts, action of alpha irradiation on, 313.
Choanephora cucurbitarum on *Capsicum annuum*, 357.
Choerostrongylus pudendotectus, early developmental stages, U.S.D.A. 107.
Cholesterol—
determination, adaptation for colorimeter of Schoenheimer and Sperry method, 10.
floridin activation of, Iowa 86.
suspensions, electrophoresis of, Minn. 582.
Chortophila brassicae, see Cabbage maggot.
Chortophila cilicrura, see Seed-corn maggot.
Chromosomes—
behavior in blackberry-raspberry hybrids, 465.
in black Mexican corn, Iowa 334.
in Compositae, number at meiosis in microspore mother cells, 464.
in seeds of fruit trees, preparations for, N.Y.State 191.
number in *Gladiolus*, 81.
number in Leguminosae, 607.
Chrysanthemum—
bud formation, effect of day length, 349.
diseases, summary, 652.
flower bud initiation and development, factors affecting, 349.
leaf miner, notes, Conn.[New Haven] 657.
wilt, control, N.J. 638.
Chrysanthemums, hardy, varieties, Ohio 340, 492.
Chrysis shanghaiensis, life history and habits, 526.
Chrysomphalus—
aonidum, see Red scale, Florida.
aurantii, see Red scale, California.
Chrysothamnus, Capitophorus aphids infesting, 812.
Chufas, culture experiments, Fla. 616.

Chufas, fertilizer experiments, Fla. 615.
Cicada—
nerve lesions after paralysis by killer wasp, 379.
periodical, control in a grove of century-old oaks, 227.
periodical, in Michigan for 1936, Mich 227.
periodical, studies, U.S D.A. 77.
Cicadella n.sp., notes, 379.
Cider making with New England apples, Mass. 436.
Cider, sweet, freezing storage, relation to microbial destruction and quality, 304.
Cimex—
hemipterus, effect of low temperatures, 811.
lectularius, *see* Bedbugs.
Cirphis unipuncta, *see* Armyworms.
Citric acid—
in food products, 5.
small amounts, determination in biological material, 745.
Citron charcoal rot, notes, Tex. 57.
Citrus—
and sugarcane sirup blends, Fla. 717.
aphid, green, notes, Fla. 658.
blight due to *Phytophthora faberi*, 207.
blight, history and symptoms, Fla. 651.
bronzing due to magnesium deficiency, 651.
bronzing or copper leaf, effect of lime treatments, Fla. 636.
bud union effect in, 50.
canker eradication, U.S.D.A. 55.
chlorosis, control, 652.
concentrated fertilizers for, Fla. 626.
die-back, studies, Fla. 637.
diseases, control, 208.
diseases in British Guiana, 357.
effect of mulching, Fla. 626.
effect of zinc, Fla. 626.
fruits—*see also* Lemons, Oranges, *etc.*
behavior under special respiratory conditions, 784.
carlot shipments from stations in United States, U.S.D.A. 276.
decay in storage, Fla. 637.
effect of frost of January 1934 in India, 12.
Florida, cost of production and grove organization, Fla. 711.
in nutrition, 878.
green bug, biology and control, 228.
gummosis, new outbreaks, treatments, Fla. 636.
insect pests in California, control, 656.
insects affecting, 806.
insects, control in Florida, trend, 663.
insects, effect of freeze of 1934, 662.
leaves, trunk growth and water relation, 491.
maturity, sugar and acid as index, Fla 626.
melanose, control, 222; Fla. 637.
mushroom root rot, notes, Fla. 637.
Citrus—Continued.
nucellar embryony in, artificial control, 31.
orchards, irrigation, use of limited water supply, 702.
outlook charts, U.S.D.A. 120.
packing houses and equipment, gases as fungicides for, Calif. 369.
potash sources for, Fla. 626.
propagation experiments, Fla. 626.
properties, absentee ownership, Fla. 126.
red mite, control, 224.
Research Laboratory, Florida, establishment, 896.
roots, earth pearls of, 667.
rootstock experiments at Mt. Albert test area, 50.
rootstock resistance tests against *Phymatotrichum omnivorum*, Tex. 57.
rootstock, unusual, 784.
rootstocks for, Tex. 45
rust mite, control, 387; Tex. 78.
scab, Australian, cause, 506.
scab, control, 223; Fla. 637.
scab on *Hesperethusa crenulata*, 368.
scab organism, generic status, 505.
seedlings, *Rhizoctonia* damping-off, control, Calif. 70.
stem-end rot, control, 222; Fla. 637.
stock immune to *Phytophthora parasitica*, breeding, 505.
thrips on oranges, tests of dusts for, U.S D.A. 655.
tree decline, cause, Ariz. 70.
trees and fruits, composition, effect of potash and nitrogen sources, Fla. 626.
varieties, Tex. 45.
varieties, new, descriptions, Calif. 50.
whitefly, *see* Whitefly, citrus.
Cladosporium—
cucumerinum, notes, Me. 357.
fulvum, nature and control, 787.
fulvum, resistance to, 646.
spp., isolation from black knots, 68.
Clay—
colloids of Missouri, tendency to develop clay pans, Mo. 15.
particles in a soil crumb, binding forces between, 448.
products, utilization in farm building construction, Iowa 111.
Putnam, hydration and physicochemical properties, Mo. 15.
retention of phosphate by, factors affecting, 598.
Clays, surface behavior, 166.
Clemson College, notes, 736.
Clidemia hirta in Fiji, biological control, 811.
Climate—*see also* Meteorology.
of Puerto Rico, relation to agriculture, P.R. 746.
Climatic variables in Corn Belt, intercorrelations between, U.S.D.A. 590.
Climatological data, Ohio 305; U.S.D.A. 14, 161, 444, 590.
Clitocybe tabescens, notes, Fla. 637.

Clonorchis sinensis, notes, 400.
Clostridium—
bifermentans and *C. centrosporogenes*, antigenic relations, 606.
centrosporogenes and *C. bifermentans*, antigenic relations, 606.
welchii, cause of losses of lambs, Colo. 252.
welchii, type B, Bloedpens strain, 538
Clothes moth, webbing—
comparison of fumigants, 655.
digestion of keratin by larvae, 815.
Clothes moths, attack on soiled spots in cloth, Conn.[New Haven] 374.
Clothing—
costs for freshman college girls, 734.
of children, kinds and costs, 575.
Clouds and wind, effect on microclimatic temperatures in a growth of conifers, 12.
Clover—
alsike, breeding, N.J. 616.
alsike, mosaic of, Idaho 637.
Ladino, adaptability for pastures, [Conn.]Storrs 194.
Ladino, breeding, Idaho 616.
Ladino, for western Oregon, Oreg. 669.
mildew, powdery, studies, 642.
red, alfalfa and sweetclover, relative value as soil-building crops, Iowa 14.
red and alsike, effect of cutting at different times, Iowa 35.
red and alsike, residual effects, [N.Y.] Cornell 450.
red, breeding, N.J. 616; Tenn. 767.
red, growth, effect of soil reaction, Ohio 331.
red, injury by potato leafhopper, 517; Ky. 518.
red, irrigation experiments, Idaho 616.
red, mosaic of, Idaho 637.
red, nitrogen fixation in, relation to carbon assimilation, 760.
red, variety tests, Idaho 616; Iowa 35; N.J. 616; Wash. 38.
red, winterhardiness, relation to physical properties and chemical composition, Md. 476.
response to soil reaction, R.I. 767.
root weevil on strawberries, Oreg. 232.
stem rot, new host species, 212.
susceptibility to *Rhizoctonia solani*, 61.
sweet, *see* Sweetclover.
Tennessee anthracnose-resistant, tests in Western States, Tenn. 767.
variety tests, Fla. 615; Tex. 38.
viruses, identification, 62.
Club work, *see* 4-H poultry club.
Cnephasia virgaureana injuries to strawberry culture in eastern France, 374.
Cnidocampa flavescens, *see* Oriental moth.
Coat character, rexoid, in mice, 610.
Coat colors in *Peromyscus maniculatus*, 610
Coats, women's cloth, quality guides in buying, U.S.D.A. 890.
Coccidae—
of Spain and Morocco, 807.
on sandal foliage, 813.
Coccidiosis—
chronic, studies, 259.
control, Mich. 691.
control, factors affecting, Wis. 538.
notes, [Conn.]Storrs 252.
of gray and stone partridge, 403.
of poultry, 401; P.R. 840.
of rats, effect of diet, 253.
parasite from chicks in laying pullets, Mich. 259.
sage chickens as carriers, Wyo. 103.
Coccobacilliform bodies in birds infected with coryza of slow onset, 402.
Coccophagus spp., remarkable phenomenon of reproduction in, 512.
Cochliomyia americana, *see* Screwworm(s).
Cochliomyia macellaria, *see* Screwworm(s).
Cockchafer-infested forests, selection system in, 656.
Cocklebur, poisonous to livestock in Florida, Fla. 690.
Cockroaches, temperature and humidity relations and thermal deathpoint, 810.
Coconut beetle, control by trap crops infected with green muscardine fungus, 208.
Coconut bug, green—
cause of immature nut fall in coconut, 379.
notes, 81.
Coconut—
diseases, 208.
diseases in British Guiana, 357.
leaf miner and parasites, development, relation to weather conditions, 381.
oil cake and cassava meal, feeding value, Hawaii 395, 534.
oil, feeding, effect on beef, 528; Iowa 86.
palm insects in British Solomon Islands, 376.
palms, brown rot of roots and stems, cause, 505.
Coconuts, composition, nutritive value, and use, Hawaii 879.
Codling moth—
bait and light trap experiments, N.Mex. 77.
bait solutions for, 376.
bait traps, heating by electricity, 265.
bionomics and control, Iowa 77.
brood study in southeastern Nebraska, Nebr. 224.
catcher for laboratory use, U.S.D.A. 76.
collection and emergence, N.J. 813.
control, 656: Ind. 778; Mo. 77; Ohio 374.
control and spray combinations, Idaho 658.
control, calcium arsenate in, present status, 375.
control in Canada, 381.
control in Washington, 375.
control, new methods, 381.
control, nonarsenicals and nonlead arsenicals for, Wash. 79.
control, spray recommendations for western New York, 375.

Codling moth—Continued.
control, summer oil sprays for, 814.
control with electric insect traps, Ind. 851.
control with impregnated oil, 521.
control with insecticides, status, 375.
control with nicotine sprays, Mass. 512.
control with phenothiazine, tests, U.S.D.A. 655.
control with zinc arsenate, Mich. 658.
eggs, obtaining, oviposition cage for, U.S.D.A. 511.
eggs, ovicides for, tests, 670.
experiments in New Jersey, 520.
injury, variations in northwestern Arkansas, 669.
insecticide tests, Ind. 806.
insecticides, effect of procedure on performance, 520.
larvae, phenothiazine laboratory work with, 670.
life cycle, effect of 1934 drought, 814.
new insecticide for, preparation, Mo. 77.
parasitism, effect of orchard practices, 659.
spraying experiments in Pennsylvania, 670.
studies, N.J. 658; S.C. 78.
Cod-liver oil—
and irradiated and metabolized milk, comparison for vitamin D content, 246.
and irradiated ergosterol, antirachitic potency, comparison, 429.
antirachitic efficiency, Ohio 395.
concentrate in milk, rickets prevention with, 430.
deaminized v. untreated, feeding to poultry, effect, 681.
effect on retention of mineral element during pregnancy, 724.
fed to hens, effect on embryo mortality and on calcium and phosphorus content, Ky. 825.
feeding to cows, effect on composition of blood and milk, 685.
Coeloides dendroctoni, biology, 386.
Coffea, plant organisms on, list, 369.
Coffee—
berry beetle borer, notes, 808.
berry borer, biology, 818.
Columnaris and Puerto Rican varieties of Arabian, comparative yields, P.R. 778.
Columnaris, root rot resistance, P.R. 778.
composition, nutritive value, and use, Hawaii 879.
diseases in British Guiana, 357.
effect of shading, P.R. 778.
leaf-eating caterpillar, control, 82.
leaf miner, notes, 808.
plant, culture and handling, Hawaii 339.
thrips, cause of outbreaks, 378.
Colds, studies, Mass. 537.
Coleophora maltvorella, *see* Pistol case bearer.
Coleoptera of India, immature stages, 79.
Coleus—
crown and root rot, Tex. 57.
leaf fall in, role of auxin, 456.
Coli-aerogenes group—
action on *Erythrosin*, Mass. 436.
bacteria in commercial fish and fillets, detection and significance, 720.
methyl red reactions, Eijkman test, and dye tolerance, Mass. 436.
Colletotrichum—
fragariae, notes, 788; Fla. 637.
fuscum on *Digitalis purpurea*, U.S.D.A. 496.
gloeosporioides, effect of gases, Calif. 369.
graminicolum, cause of stem and root disease of oats, 59.
lagenarium, notes, 495.
Colloid chemistry of cellulosic materials, U.S.D.A. 740.
Colloidal soil materials, effect on toxicity of calcium arsenate to millet, 448.
Colloids—
argillaceous and humic, comparative effects of lime and magnesium, 453.
of great soil groups, composition, 593.
of Hawaiian soils, composition, Hawaii 306.
soil, chemical and physical properties, U.S.D.A. 18.
soil, hydration, relation to crystal structure, 307.
soil, liquid intake by and swelling, Mo. 15.
soil, relation to climate, Mo. 15.
soil, relation to pisé or rammed earth walls, S.Dak. 703.
Color—
inheritance in beets, 188.
inheritance in Collies, 32.
inheritance in potatoes, 190.
inheritance in swine, 191.
mutation in mice, new sublethal, 32.
Colorado College, notes, 894.
Colorado Station, notes, 142, 894.
Colorado Station, report, 286.
Colorimeter, photoelectric new type, description, 295.
Colts—
draft, growth in, Mo. 86; N.Dak. 530.
draft, limited v. liberal rations for, Mich. 676.
preparation of feed for, Iowa 824.
studies, Iowa 86.
Combines—
cost data, 706.
cost in 1934, Ind. 863.
small-size, high-speed, all-crop, Idaho 701.
studies, Ind. 851.
Community sale, Okla. 269.
Compositae, cytological observations, 464.
Concrete—
floor construction, precast joist-precast slab, load performance tests, 704.

Concrete—Continued.
speed portland and blended, physical properties, 263.
structures, design, 263.
Conifers—
germination methods of California, 785.
leaf and stem blight, control, Tex. 57.
root disease due to *Phytophthora cambivora*, U.S.D.A. 789.
seed, storage, 206.
seed viability, effect of moisture content and kiln temperature, 785.
species tests, Nebr. 197.
Coniothyrium sp., notes, 68.
Connecticut—
[New Haven] Station, notes, 576.
[New Haven] Station, report, 141, 431
Storrs Station, report, 141, 286.
Conotrachelus nenuphar, see Plum curculio.
Conservation and outdoor recreation in Kentucky, 270.
Consumption—
economics of, treatise, 891.
standards, changes in, during a depression, Mich. 891.
Cookers, steam pressure, accuracy of pressure gages, Nebr. 286.
Cooking utensils of different materials, application of heat to, Iowa 140.
Cooperation—*see also* Marketing.
in agriculture, bibliography, 869.
Cooperative—
business organizations of farmers, statistics, 869.
purchasing associations, farmers', kinds of commodities purchased, Wis. 555.
Cooperatives, financing, Wash. 126.
Cooperia curticei, egg producing capacity, 696.
Copper—
availability from natural sources, Wis. 564.
availability in ration for laying hens, Wis. 530.
compared with new materials for heat transference by dairy equipment, Wis. 535.
compounds, insoluble, as fungicides, Ohio 357.
compounds, insoluble, value in vegetable disease control, 647.
deficiency in sugar beets, 502.
function in soils and relation to availability of iron and manganese, 454.
fungicides and cuprous oxide, relative adherence, 495.
fungicides for tomatoes, tests, R.I. 789.
fungicides, test on peaches, 788.
in flora of copper-tailing region, 180.
in urine of children, 567.
injury to foliage, mechanism, N.J. 638.
oxide, red, for rose black spot, 653.
poisoning, chronic, Tex. 103.
role in peat and muck soils of Everglades, Fla. 591.
Copper—Continued.
sprays, injurious effects, 355.
sulfate and salt mixture for gastrointestinal parasites of sheep, W.Va. 847.
sulfate, effect on yield and quality of oranges, 627.
sulfate tests, Tex. 57.
sulfate, value as plant nutrient, 317.
sulfate with Wyo-Jel v. bordeaux mixture on potatoes, Mass. 497.
toxic effect on potatoes, 215.
use in curing goat's milk anemia, Wis. 535.
value in normal calf rations, Ohio 395.
Corn—
acreage and production, S.C. 120.
amount in laying rations, Ind. 820.
and-cob meal v. shelled corn for fattening yearlings and calves, Ohio 239.
and grain sorghum, interplanting, effect, Tex. 38.
and grain sorghums, comparison, Tex. 38.
and legumes, interplanting, S.C. 37.
applied botanical research on, Iowa 334.
bacterial wilt—
dissemination, Iowa 360.
forecast of incidence, U.S.D.A. 207.
insect vectors, 522.
notes, Me. 357.
resistance, genetic studies, 494; Iowa 55, 321.
Belt, climatic variables in, intercorrelations between, U.S.D.A. 590.
Belt husbandry, changes in, 527.
Belt, land use in, 476.
billbugs, studies, Iowa 77; S.C. 78.
Black Mexican inbreds and hybrids, behavior of extra chromosomes in, Iowa 334.
borer, European—
control, 374; Conn.[New Haven] 657.
cooperative egg parasitism investigation, Conn.[New Haven] 657.
distribution and prevalence, relation to evaporation rates, Ohio 443.
in Indiana, Ind. 815.
infestation and date of planting, Conn.[New Haven] 374.
mechanical control, Ind. 851.
mortality of first instar larvae, Ohio 374.
notes, Ind. 806.
on eastern shore of Virginia, 230.
resistance and tolerance of strains of corn to, U.S.D.A. 381.
resistance to, breeding of corn for, Mich. 616.
resistant hybrid variety of corn to, Mich. 769.
worms in cake, Conn.[New Haven] 657.

Corn—Continued.
bran, added to basal ration, effect on growth rate and slipped tendon in chicks, 828.
breeding, Fla. 615; Ga.Coastal Plain 194; N.Dak. 474; N.J. 616; Nebr. 195; Tex. 38.
breeding for borer resistance, Mich. 616.
byproducts, fermentation products from fungi action, N.J. 24.
characteristics in relation to industrial utilization, Iowa 4.
checkrowers, 4-row, accuracy, Iowa 111.
chinch bug resistance in second brood, Iowa 336.
chlorophyll formation, effect of titanous chloride, 25.
chlorosis, treatments, Fla. 636.
composition and strength of stalk, correlation, Iowa 36.
cost of harvesting by different methods, S.C. 120.
costs and yields, effect of tillage methods, Mo. 111.
culture experiments, S.C. 37; Tex. 38; Wyo. 39.
curing and storage studies, Iowa 36.
damage by flat wireworm in Canada, 817.
Diplodia dry rot on, Iowa 55.
disease caused by *Physoderma zeae maydis*, Fla. 636.
disease-free and diseased, effect of seed treatment, 495.
diseases, studies, 789; Ind. 789.
double cross yields in, prediction, 621.
drought-injured, effect of feeding to cattle, Iowa 102.
ear rot diseases, Fla. 636.
ear rot fungi, prevalence, U.S.D.A. 55.
ear rot prevalence, relation to coverage by husks, U.S.D.A. 635.
ear rots, losses in Illinois, U.S.D.A. 207.
early maturity, effect of phosphorus, S.Dak. 617.
earworm, cannibalistic habits, U.S.D.A. 229.
earworm, control, 374; Conn.[New Haven] 374.
earworm control, lead arsenate and wetting agents for, 512.
earworm, control on western Long Island, 229.
earworm, emergency studies, Iowa 77.
earworm, important natural enemy of, U.S.D.A. 81.
earworm, number of instars, Dyar's rule for corroborating, 380.
earworm, studies, Ga. 519.
effect of inbreeding and selection within inbred lines, Iowa 322.
effect on succeeding crops, Tex. 38.
Euchlaena, and *Tripsacum*, genetic and cytological relations, Tex. 38.
feeding value, Colo. 531.
feeding value for pigs, Fla. 675.
fertilizer experiments, Fla. 615; Ga. Coastal Plain 194; La. 474; Tex. 38; Wash. 38.
fertilizers, grades of, 473.
finely chopped fodder v. silage for fattening steers, N.Dak. 529.
flea beetle, overwintering adults harboring *Aplanobacter stewarti*, 360.
flea beetle, vector of bacterial wilt, 522.
fodder and stover, grades, relation to methods of curing, storing, and baling, Iowa 36.
futures on Chicago Board of Trade, open commitments in, analysis, U.S.D.A. 558.
germination, injury by cold of 12° F., Wis. 475.
gluten feed, effect on acidity of freshly drawn milk, [Conn.]Storrs 243.
gluten meal, feeding value, Kans. 531.
grinding for swine, Pa. 824.
ground shelled, as ration for dairy cows, Ind. 830.
growing and harvesting, man labor, and horse and tractor work used in, Mo. 119.
hail damage, Iowa 770.
harvesting machinery, S.Dak. 702.
hybrid No. 561 a borer-resistant field corn, Mich. 769.
hybrid seed, merits of, Wis. 475.
hybrid vigor in, 30.
hybridization, Ohio 331.
hybrids, agronomic characters, Minn. 477.
hybrids, double-cross, resistance and tolerance to borer infestation, U.S.D.A. 381.
hybrids, growth response on soil types, Iowa 36.
improvement, Iowa 35.
improvement, six decades of and future outlook, Iowa 335.
in rotation with different legumes, Miss. 331.
inbred lines, research, Iowa 35.
industrial utilization, U.S.D.A. 442.
inheritance studies, S.Dak. 769; Tex. 38; Wash. 38.
interplanted with soybeans and variously spaced, La. 474.
irradiation, genetic and cytological effects, Mo. 36.
Krug, top crosses, accumulation of minerals in, Ohio 331.
leaf area and growth rate, Iowa 335.
linkage studies, Colo. 194.
loss mutation in, Iowa 334.
magnesium requirements, Va.Truck 779.
maturity belts in State, determination, Wis. 475.
modification of a Mendelian ratio by pollen treatments, 188.
new mutants in, Iowa 334.

Corn—Continued.
nitrogenous fertilizers on, effect, 472.
outlook charts, U.S.D.A. 120.
Phytomonas stewarti infected, histological changes in resistant and susceptible strains, 496.
pickers, efficiency, Iowa 111.
plant for wintering stock calves, 527.
plant, ontogeny, early differentiation of stem and root structures, Iowa, 335.
plant, various parts, antirachitic activity at time of ensiling, Mich. 236
planter, fertilizer attachments, Mo. 111.
planters, fertilizer tests with, Ohio 408.
planting and cultivation, Miss. 769.
planting, basin method, Iowa 111.
plants grown in culture solutions at pH values of 3.0 to 8.0, iron and minerals, in, N.J. 601.
prices, 1931–32 by farming areas of State, Iowa 119.
production, future, Iowa 334.
production, mechanical methods, Iowa 111.
resistance to bacterial wilt, Wis. 497.
response to continuous culture, Mont 616.
response to zinc and other less abundant elements, Fla. 615.
root tips, excised fragments, growth, 605.
rootworm, southern, relation to lodging in corn, Ohio 374.
rotating with crotalaria and with native cover crops, Fla. 616.
rotation experiments, Fla. 616; Ind. 767.
seed, curing with artificial heat, Iowa 36.
seed, ear and kernel characteristics, relation to yield, Iowa 36.
seed, production and distribution of hybrids and of parents, Iowa 36.
seed, State certified, N.J. 339.
seed transmission of *Helminthosporium*, 213.
seed treatment, Wyo. 58.
seed treatment, effect, relation to rate of planting, Iowa 360.
seed, treatments, physiological response of plant and pathogen, Iowa 55.
seedbed preparation for, Iowa 111.
seedbed preparation, planting, and spacing, La. 474.
seedling blight, effect of filtrates from cultures of *Diplodia zeae* on, Iowa 361.
seedlings, collapse due to excessive nutrient material in soil, Wis. 497.
seedlings, effect of soil acidity or alkalinity, Tex. 57.
seedlings, Sherman unit vitamin A value, Iowa 130.
seeds, effect of organic mercury dusts, Iowa 55.
silage, *see* Silage.
Corn—Continued.
smut, development, factors affecting, Minn. 212.
smut, effect on yield of grain, 640.
smut, latent and expressed, 494.
smut, new aspects, Iowa 361.
smut, researches, 361.
smut resistance or immunity, breeding for, Mo. 36.
smut resistant strains, Iowa 55.
smut survey, Iowa 792.
starch gels, effect of freezing on physical and microscopic character, 277.
Stewart's disease, *see* Corn bacterial wilt.
stripe disease, phloem necrosis in, 494.
sugar, use, Mass. 563.
sugar, use in production of lactic acid, Iowa 4.
susceptibility to *Rhizoctonia solani*, 61.
sweet, *see* Sweet corn.
time of planting tests, Ind. 767.
translocation of carbohydrates in, Iowa 315.
unusual damage from phosphorus soil deficiency, U.S.D.A. 789.
v. cottonseed cake as supplements for wintering ewes, Mont. 676.
varieties for silage, R.I. 769.
varieties, resistance and tolerance to borer infestation, U.S.D.A. 381.
varieties, yields and other agronomic data, U.S.D.A. 476.
variety tests, Fla. 615; Ga.Coastal Plain 194; La. 474; Miss. 331; Mo. 36; N.Dak. 474; N.J. 616; N.Mex. 36; Nebr. 195; Ohio 331; S.C. 37; Tex. 38; Utah 334; Wash. 38; Wyo. 39.
white bud, effect of zinc sulfate, Fla. 209.
white bud, studies, Fla. 636.
wilt bacteriophage of *Aplanobacter stewarti*, distribution, Ohio 357.
winter cover crops for, Ga.Coastal Plain 194.
yellow dent, histology of caryopsis, 64.
yellow, preparation of white zein from, Minn. 582.
yield test, Iowa, 1935, Iowa 41.
yields, effect of legumes and fertilizers, Ind. 767.
Corncobs, xylan from, Iowa 4.
Cornell University, notes, 736.
Cornstalk—
borer, southern, S.C. 78.
covering equipment, Ind. 851.
disease investigations, 258.
Cornstalks, carbohydrate constituents, identification, Iowa 4.
Corpora lutea—
extracts, progestin-containing, inhibition of oestrin by, 470.
in rabbits, prolonging life of, effects, 614
physiology, 470.
Corpus luteum—
formation, mechanism, and oestrogenic hormone, 327.

Corpus luteum—Continued.
hormone, studies, 326, 765.
of pregnancy, relation to anterior pituitary gland, 33.
retention, clinical treatment in cows, Mich. 257.
Corrosion, causes and prevention, treatise, 705.
Corticium—
centrifugum causing root and collar rot of delphiniums, 370.
fuciforme, notes, R.I. 789.
Corythucha ulmi, notes, Conn.[New Haven] 657.
Coryza—
infectious, of poultry, relation to *Hemophilus gallinarum*, 259; R.I. 849
uncomplicated, of domestic fowl, 402.
Cosmophila erosa caterpillars, parasite of, identity, 385.
Cosmos, fasciation and its etiology, Tex. 57.
Cost of production, *see specific crops*.
Cotton—
American, disease of malformation in India, 361.
angular leaf spot in Mississippi, 788.
anthracnoses due to five strains of *Gloeosporium*, 207.
aphid, studies, S.C. 78; Tex. 78.
bacterial leaf spot, dissemination, 788.
bollweevil resistant characters, 473.
breeding, 472, 787; N.Mex. 36; S.C. 37; Tenn. 767; Tex. 38.
breeding, importance of lint index, 472.
characters, effect of spacing, 472.
cooperative grade and staple work, progress and use, 472.
crop, Oklahoma, quality for 1935, Okla 709.
culture experiments, N.Mex. 36; S C. 37; Tenn. 767; Tex. 38.
culture in United States, 473.
disease due to *Helminthosporium gossypii*, 207.
embryo, development, 41.
fabrics, effect of variations in pressure and in length of exposure during ironing, U.S.D.A. 573.
farm prices, relation to grade and staple length, U.S.D.A. 127.
farms, dairying and feed production as supplements, La. 534.
farms, high- and low-profit, net earnings, 1931–33, Tex. 120.
fertilizer experiments, Ga.Coastal Plain 194; La. 474; N.Mex. 36; S.C. 37 Tenn. 767; Tex. 38.
fertilizer placement tests, 472.
fertilizer placement tests, cooperative, 471.
fertilizers, grades of, 473.
fertilizers, ratio of inorganic and synthetic to organic nitrogen in, 472.
fertilizers, reducing retail costs, 473.
fertilizers v. stable manure, Miss. 331
Cotton—Continued.
fiber, different lengths, device for separating, 472.
fiber length and distribution in, S.C. 37.
fiber, length, effect of fertilizers, Tex. 38.
fibers, distribution of length groups, effect of water supply during various stages, 473.
fibers from bolls at different positions on plants, U.S.D.A. 477.
fibrograph, 472.
field tests, randomized, efficiency of single and double restrictions in, Ark. 336.
flea hopper, control, 227; Tex. 516.
flea hopper, studies, S.C. 78; Tex. 78.
flooding experiment, Tex. 58.
Fusarium wilt, field studies, 788.
genetic studies, S.C. 37.
gin associations, cooperative, account principles for, 273.
gin saws and ribs, care and maintenance, U.S.D.A. 856.
ginning, cooperative, financial aspects, Okla. 709.
ginning plants, power requirements, 408, 472.
ginning, studies, 471.
gins and ginning, La. 770.
gins, cooperative, of Texas, costs, income and financial status, Tex. 124.
gins, effects of returning classification cards to patrons, Okla. 709.
gins, regulation as public utilities, results, Okla. 870.
grade and staple length of Georgia crop, Ga. 412.
grade, color, and strength, effect of weathering, Tex. 38.
grade, staple length, and tenderability, U.S.D.A. 273.
inheritance studies, Tex. 38.
insects, field plat poison tests in 1934, S.C. 78.
insects, little-known, 513.
interspecific hybrids and behavior of F_1 plants, 189.
irrigation experiments, N.Mex. 36; Tex. 38.
leaf roller in Punjab, 79.
leaf worm in Florida, 230.
lint, application of seed cotton fibrograph to, 572.
lint, fiber length analysis, application of fibrograph to, 473.
lint, quality, effects of gin-saw speed and seed-roll density, U.S.D.A. 117.
lint studies, Tenn. 767.
linters, American, standard grades for, U.S.D.A. 477.
machinery, field plat investigations, 471.
marketing practices, N.C. 124.
mechanical harvesting, Tex. 111.
mineral nutrients in sap and tissue, effect of fertilizers, 473.

Cotton—Continued.
Missouri, farm prices and quality, Mo 273.
New Mexico, grades and staple, N Mex. 36.
new thrips on, 377.
nitrogenous fertilizers on, effect, 472.
nutrition studies, S.C. 37.
one variety community, work in Georgia, 473.
outlook charts, U.S D A. 120.
outlook, world, 473.
plant at various stages, nitrogen, phosphorus, and calcium in, 472.
plant research, coordinated program, 473.
plant, transport in, 459.
pollen germination tests, Tenn. 767.
prices, S.C. 120.
prices, response to acreage control, dollar devaluation, and 12-cent loan, Okla. 269.
production—
and marketing in United States, financing, U.S D.A. 124.
foreign, 472, 473.
in Mexico, U.S.D.A. 865.
in northeast Brazil, U.S D.A. 125
in United States, government control, U.S.D.A. 273.
tests for fiber, Miss. 331.
program, new, lessons from old program, Okla. 269.
programs and tenancy, Okla. 412.
quality, trends in, and opportunities for improving, 473.
root development in Louisiana soils, 471.
root rot—
fungus, effect of ammonia-nitrogen on growth, 788.
fungus, persistent strands in Texas, 787.
in Texas, 787.
insects possible distributing agents, 373.
organism, longevity in moist laboratory soil, 643
organism on winter and spring weeds of Texas, 643.
relation to soil composition, Tex 65.
sclerotia, separating from soil samples, apparatus and procedure, 213.
studies, Tex. 56, 57.
rotation studies, Fla. 616.
sea-island, hybridization experiments, S.C. 37.
seed, *see* Cottonseed.
seedbed preparation, planting, and spacing, La. 474.
seedling diseases, S.C. 56.
seedlings, effect of soil acidity or alkalinity, Tex. 57.
sore-shin or damping-off, etiology, 788.
sources of nitrogen for, Tex. 38.
Cotton—Continued.
spacing tests, 472.
staple length, percentage distribution, S C. 120.
stem weevil in Philippines, identity, 385.
stem weevil pest in south India, 818.
technic of crossing, Tex. 38.
under AAA, 413.
upland, lint percentage in, relation to green color, 472.
varieties adapted to mechanical harvesting, development, Tex. 38.
varieties, resistance to jassid bugs, 808.
variety tests, Ga.Coastal Plain 194; La. 474; Miss, 331; Mo. 36; N Mex. 36; S.C. 37; Tenn. 767; Tex. 38.
Verticillium wilt, 788.
Verticillium wilt resistant strains, Tenn. 790.
wilt and rust, control with fertilizers, 644.
wilt due to *Fusarium*, 787.
wilt, effect on quality of lint and seed, Tex. 57.
wilt fungus, reaction to toxic dyes, 788.
wilt in Arkansas, tests, U.S.D.A. 207.
wilt, insects possible distributing agents, 373.
wilt resistant, adapted to Gulf Coastal Plains, 474, 788.
wilt resistant varieties, breeding, 472, 787.
winter cover crops for, Ga.Coastal Plain 194.
yield trials, efficiency of randomization and analysis of variance in, 472.
yields and stands, factors affecting, 770.
Cottonseed—
anatomy and microchemistry, Tex. 38.
cake, feeding value, Colo. 531; Nebr. 239.
cake, hardness, relation to suitability for feeding, Tex. 236.
cake v. corn as supplements for wintering ewes, Mont. 676.
development and germinating ability, environmental factors in, 473.
germination, effect of origin, S C. 56.
hulls as roughages in fattening steers, Fla. 675.
in cattle fattening rations, Tex. 88.
insects infesting, 655.
light and heavy, comparative effects, 472.
meal and hulls, feeding to fattening steers, methods, S C. 87.
meal and hulls for lactating dairy cows, Tex. 98.
meal, effect on cows and on vitamin A in butterfat, N.Mex. 98.
meal, feeding value, Kans. 531; Tex. 88.
meal, hydraulic and expeller, for pigs, Ohio 388.
meal, nitrogen carriers to replace, comparison, Conn.[New Haven] 330.

Cottonseed—Continued.
meal v. linseed meal, palatability, Mich. 821.
meal v. tankage for dairy cows, N.Dak. 535.
outlook charts, U.S.D.A. 120.
poor germination, in Georgia, U.S.D.A. 356.
treated and delinted, planting, Tex. 38
treatment and storage, S.C. 56.
treatments in South Carolina, 788; S.C. 37.
vertical drier for, U.S.D.A. 553.
Cottonwood chlorosis, control by iron salts, Wyo. 58.
Counties, reorganization or consolidation, 554.
County organization for program planning in Virginia, 714.
Cover crop tops, fertilizing value, S.C. 37.
Cover crops—
for orchards, Wash. 45.
variety tests, Fla. 615.
winter, comparison, Tenn. 767.
winter, comparison for cotton and corn, La. 474.
Cow, granulomatous nasal swelling in, 694.
Cowpea—
aphid on cotton in South Carolina, 226.
seedlings, effect of soil acidity or alkalinity, Tex. 57.
weevil, notes, Tenn. 806.
Cowpeas—
effect of zinc sulfate, Fla. 210.
proteins of, 739.
variety resistant to *Fusarium* wilt and nematode root knot, 495.
variety tests, Fla. 615; Ga.Coastal Plain 194; N.J. 616; N.Mex. 36; S.C. 37; Tex. 38.
Verticillium affecting, U.S.D.A. 356.
Cows—*see also* Calves, Cattle, *and* Heifers.
barley v. corn for, N.Dak. 535.
basal metabolism, liability of, N.H. 535.
beef, mineral supplements for, Wyo. 89.
breeding, disadvantage of feeding for heavy grains during winter, Mont. 676.
dairy, calcium and phosphorus requirements, Vt. 834.
dairy, feeding experiments, Hawaii 396.
feeding experiment with legume hay, Ind. 834.
grain and roughage v. grain alone for, Nebr. 243.
hemolytic streptococci in tonsils, 841.
Holstein, breeding circuit, results, N.Dak. 535.
Holstein, difference between Eckles standard and observed weight and height, Idaho 683.
Holstein, high producing, feed utilizing efficiency, Idaho 683.
lactating, effect of intravenous injections of sugar, 832.
management on small farms, U.S.D.A. 86.
milk, loafing barn for, Mo. 111.
Cows—Continued.
milk production, *see* Milk production.
milking, grazing tests, S.C. 98.
on pasture, supplementary ration for, Mass. 534.
pregnancy in, hormonal method for detection, 325.
productive and reproductive efficiency, relation to length of service period, 527.
records, *see* Dairy herd records.
retained corpus luteum in, treatment, Mich. 257.
rumination, effect of feeds, N.H. 535.
Shorthorn, milk of typical herd, 686.
udders, *see* Udder(s).
weight, effect of pregnancy and parturition, Nebr. 395.
wet and dry, comparative cost of wintering, Ind. 819.
winter feeding, simple v. complex ration for, Mich. 823.
wintering, digester tankage v. cottonseed meal for, Fla. 675.
Crab apples—
tests, Alaska Col. 778.
variety tests, Wyo. 46.
Crab meat, studies, Mass. 563.
Crab, moala, iodine content, Hawaii 415.
Cranberries—
breeding, N.J. 627.
chemical study, Mass. 436.
effect on intestinal putrefaction, Mass. 436.
fertilizer experiments, N.J. 627; Wis. 445.
spraying and dusting and storage tests, Mass. 497.
storage and utilization, Mass. 436.
Cranberry—
bog weeds, control, Mass. 474.
bogs, lime-sulfur spraying tests, Wash. 58.
bogs, weeds in, control, Wash. 38.
false blossom resistant strains, development, Mass. 497.
fruitworm, parasitism, Mass. 512.
insects, injurious and beneficial, Mass. 512.
pests, control, N.J. 627.
vines, injury, relation to oxygen in flooding water, Mass. 497.
Crapemyrtle, response to lime, Tenn. 779.
Cream—
Babcock testing, Mo. 246.
Babcock testing and other methods of analyzing, Nebr. 687.
churning process, 248.
consumption, yearly per capita in Cleveland, Ohio 412.
distribution, cost, Me. 411.
fat globules, substances adsorbed on, relation to churning, 248.
from milk of cows in advanced lactation, churnability, effect of lipolysis, 838.
frozen, destruction of fat emulsion in, 838.

Cream—Continued.
frozen, storage, changes that occur in, Mass. 534.
good quality, importance of sterilizing of separator, Idaho 683.
grading for butter making, Ind. 831.
neutralization for butter making, 838.
quality and butter quality, correlation, Wash. 99.
quality, relation to amino nitrogen in, 687.
sweet and sour farm-skimmed, enzymes in, Ind. 831.
vitamin D in, 426.
whipped, properties, Mass. 534.
Creameries—
distribution and costs of steam, electrical power, and labor in, Idaho 701.
power and labor utilization in, Idaho 701.
Creamery—
license division, report, Ind. 537.
operating efficiency, Calif. 711.
wastes, purification, effect of nature of filling material and dosing cycle, 708.
Creatinine determination, improvements in micromethod, 296.
Creeping Jennie, annual spread and control, Iowa 35.
Crest and hernia in fowls due to single gene, 468.
Cricetus cricetus, biology, 373.
Cricket—
black field, serious pest in South Dakota, S.Dak. 81.
field, control, N.Dak 512.
house, infestations from city refuse dumps, 227.
Crioceris asparagi, *see* Asparagus beetles.
Cronartium—
cerebrum aecia, *Tuberculina maxima* on, 209.
ribicola, *see* White pine blister rust
Crop—
diseases, Tex. 57.
diseases, new, in India, 357.
insurance, form, by soil inoculant inspection, N.Y.State 141.
land, percentages in small grain, and in hay, Wis. 555.
reports, U.S.D.A. 128, 414, 560, 712, 871.
rotations, *see* Rotation of crops.
Crops—*see also* Forage crops *and specific kinds.*
composition, Iowa 15.
composition and quality, in muck soils, Mich. 171.
effect on succeeding crops, R.I. 767
frost damage in India, January 1934, 12.
greenhouse, growth and flowering, effect of soil temperature. 349.
greenhouse, nutrient deficiencies in, method for study, 349.
growth, effect of fertilizers, Iowa 14.
Crops—Continued.
growth on Everglades peat, response to green manuring, 451.
growth response to fertilizers, S.C. 37.
growth response to lime and potash, S.C. 16.
improvement, propagable vegetative variations in, 627.
indicators of nutritional status, 197.
irrigation, costs in 1933, N.Mex. 120.
management in Delaware County, [N. Y.]Cornell 20.
on different soil types, response to phosphorus, 452.
production and soil management studies, Utah 309.
production in Tennessee, regional grouping, 862.
production, relation to fertilizer reaction and soil amendments, 455.
relation to weather, Kans. 12.
response to fertilizers, determination, 472.
soil acidity, liming, and fertilizer recommendations, 473.
soil-building, relative value of sweetclover, alfalfa, and red clover, Iowa 14.
suitable for livestock feeding, Ala.Tuskegee 389.
temporary grazing, 472.
tests for hogging off, Miss. 331.
value of outfield experiments in Louisiana, 473.
winter killing under northern conditions, causes, 331.
wintering, effect of snow cover, 305.
yields, climatic factors affecting, 12.
yields, effect of cropping systems, Ohio 331.
yields per acre, S.C. 120
yields, relation to soil types, 473.
Crotalaria—
culture experiments, Ga.Coastal Plain 194.
feeding value, Fla. 683.
rotation studies, Fla. 616.
seed, effect on poultry, Fla. 675.
studies, S.C. 37.
varieties, production tests, La. 474.
variety tests, Ga.Coastal Plain 194; S.C. 37; Tex. 38.
Crotalaria—
intermedia, ensilability, Fla. 683.
intermedia, planting dates and rates, stage of cutting and haymaking, Fla. 615.
juncea, analysis and use in green manuring and fiber production, 477.
spectabilis, poisonous to livestock, 842; Fla. 690.
spp., decomposition, comparative rate, Fla. 591.
Crown gall—
bacteria and infected host tissues, morphological relations, 208.
bacteria, pathogenic and nonpathogenic, nitrogen metabolism, Wis. 407.

Crown gall—Continued.
bacteria, pathogenic and nonpathogenic, physiological studies, 495; Wis. 497.
bacteria, pathogenicity, relation to viscosity of gums produced, Wis. 497.
effect on apple orchards, 788.
effect on death rate of trees in test orchard, 220.
studies, electrical potentials found in, 495.
Crows, parasitism and tuberculosis in, 851.
Crucifer clubroot—
control, N.J. 638.
lime and calcium cyanamide for control, Conn.[New Haven] 356.
resistance and volatile oil content, Wis. 497.
Cruciferae, oleiferous, cytological studies, 322.
Crucifers—
in western Morocco, pyralid injurious to, 374.
new Ecuadorian flea beetle injuring, 671.
Cryolite, new and improved form for control of beetles, Tenn. 83.
Cryptococcus fagi, see Beech scale.
Cryptohypnus abbreviatus, notes, Me. 817.
Cryptolaemus montrouzieri, notes, Mass. 512.
Cube—
and derris in dust mixtures, comparative toxicity, 224.
kaolin dust, effective use against insects, Idaho 658.
root, studies, N.J. 658.
Cucumber—
beetle, striped, control, Ind. 806; Mass. 512.
beetles, effect of Alorco, Tenn. 84.
downy mildew control, 788; S.C. 56.
scab resistance, breeding for, Me. 357.
Cucumbers—
kerosene and petroleum oils in, distribution, 62.
magnesium requirements, Va.Truck 779.
production for pickling, Mich. 780.
Cucurbit downy mildew, Fla. 636.
Cucurbits—
breeding, Iowa 44.
exudation in, 604.
insecticide experiments, S.C. 78.
Culex pipiens—
autogenous and anautogenous races, biology, 381.
races in, 656.
Culture, human, forms and problems of integration and methods of study, 714.
Cunninghamella—
plaque method of measuring available phosphorus in soil, 23.
sp. for measurement of soil fertility, Wis. 445.
Cupro-jabonite as possible control agent for iris rot, Tex. 57.
Cuprous oxide and copper fungicides, relative adherence, 495.
Curculionidae, new Indian, description, 385.
Curly top disease in Pacific Northwest, U.S.D.A. 55.
Currant—
anthracnose, due to *Pseudopeziza ribis*, 503.
insects, problems of, 808.
Currants—
culture experiments, Alaska Col. 778.
spray schedules for, Ohio 201.
Cutworms—
control, Mich. 658; Ohio 374.
notes, Tenn. 806.
of Nebraska, Nebr. 224.
Cyanamide—
for orchard trees, Ohio 340.
v. ammonium sulfate for apples, Mo. 44.
Cyanide—
compounds as insecticides, bibliography, U.S.D.A. 511, 655.
killing jar, improved, U.S.D.A. 76.
Cyanophoric materials, experimental feeding tests, 235.
Cyclamen mite, control on strawberries, Calif. 526.
Cylindrium sp. on walnuts, 369.
Cynomyia cadaverina, vector of encephalitis, 663.
Cyrtorhinus mundulus, parasite of sugarcane leafhopper, Hawaii.Sugar Planters' 664.
Cysteine—
determination, 10.
determination in butyl alcohol extracts, 158.
Cysticercus tenuicollis, notes, 400.
Cystine—
amine, substitution for cystine in rat diet, 723.
determination, 10.
determination in butyl alcohol extracts, 158.
Cystinyldiglycine in crystalline form, preparation, 436.
Cytology and fruit breeding, N.Y.State 191.
Daffodil stripe disease, studies, 370.
Dahlias, history, culture, diseases, and pests, Mich. 51.
Dairy—
areas of United States, new map, 273.
arithmetic, typical problems in, Nebr. 687.
cattle and dairy cows, *see* Cattle *and* Cows.
farm rotation on worn-out hay lands, N.H. 474.
farming in New York, economic studies, [N.Y.]Cornell 866.
farming in Vermont during a major depression, Vt. 867.
farms, costs for labor, fertilizers, and taxes, Me. 411.
glassware, procedure of testing and standardization, N.Y.State 101.
glassware, testing, mercury calibrating machine for, N.Y.State 101.
herd improvement associations, U.S.D.A. 686.

Dairy—Continued.
herd, milk and butterfat production, Hawaii 534.
herd records of breeds and inheritance of qualities, [Conn.]Storrs 243.
herd, university Holstein-Friesian, development, Wyo. 536.
herds in southern part of State, economics of, N.H. 535.
industry, marketing research needs, 554.
marketing, classification and summary of research projects in, 554.
plant equipment, heat transference, comparison of new materials with copper, Wis. 535.
products, Babcock testing and other methods of analyzing, Nebr. 687.
products, outlook charts, U.S.D.A. 120.
ration, home-grown, Ohio 395.
show, national, in St. Louis, N.Y.State 141.
sires, *see* Bulls *and* Sires.
utensils, cleaning and sterilizing, Kans. 101.
utensils, sterilization on farms, electric steam generator for, 708.
Dairying—*see also* Creamery, Butter, Milk, *etc.*
studies, La. 534.
Dallis grass, fertilizer experiments, Fla. 615.
Dames rocket, mottling or breaking in Oregon, U.S.D.A. 636.
Damping-off—
control by sand culture method, 639.
control with formaldehyde dusts, N.J. 638.
of seedlings in greenhouses, control, Conn.[New Haven] 356.
Dams—
check, 702.
earth fill, design, 261.
rolled earth, construction, soil compaction control for, 261.
Daphne cneorum—
fertilizers for, R.I. 779.
response to different soils, R.I. 779.
Dasyneura mali, notes, Mass. 512.
Date palm inflorescence blight, 494.
Dates, variety tests, Tex. 45.
Day length—*see also* Photoperiodism.
reduction for flowering plants in greenhouse, Ohio 43.
response in Chinese cabbage, 199.
response of plants to, 755, 756.
Deer and dauerwald in Germany, 804.
Deer mice, brown and silver, 610.
Deer, Trinidad, additional parasites from, 654.
Deficiency diseases, *see* Diet deficiency *and specific diseases.*
Dehydrator for maintaining low atmospheric humidities in small incubators, U.S.D.A. 76.
Delomerista sp., parasite of western hemlock sawfly, 819.
Delphinium seeds, germination, 52.
Dematophora sp., effect of chloropicrin as soil fumigant, 638.
Dendroctonus—
monticolae, see Pine beetle, mountain.
piceaperda, see Spruce beetle, eastern.
Dendrosporium lobatum n.g. and n.sp., description, 649.
Department of Agriculture, *see* United States Department of Agriculture.
Dermacentor—
albipictus, see Tick, winter.
andersoni, vector of anaplasmosis in California, 254.
occidentalis, see Tick, Pacific coast.
variabilis, see Dog tick, American.
Dermanyssus spp. of North America, synopsis, 388.
Dermatitis—
and denuded condition of skin, differentiation, Mo. 886.
and irradiated vitamin B complex, Mo. 131.
dietary production of specific syndrome, 728.
effect of vitamin B complex carrier irradiated with ultraviolet light, 727.
nutritional factors in, 727.
relation to factors of vitamin B complex, 727.
schistosome, causative agents and snail hosts in Manitoba, 805.
Derris—
and cube in dust mixtures, comparative toxicity, 224.
as insecticide spray, stickers for, 660.
for pea aphid control, 379, 664; U.S.D.A. 655.
insecticides, studies, 674.
studies, N.J. 658.
Desiccators, stirring air in, 438.
Deuterium and hydrolysis of starch, 295.
Devil's shoestring—
insect damage to seeds, 660.
studies, N.J. 658.
toxicity, Tex. 78.
Dewberry rosette, control in Louisiana, 788.
Dextrose, water solutions saturated to, solubility-freezing point relations, 252.
Dhobie itch, equine, microfilariae associated with, 258.
Diabetes, treatment, treatise, 138.
Diabetic diets, analyses of fish and meats used in, 415.
Diabrotica—
duodecimpunctata, see Corn rootworm, southern.
vittata, see Cucumber beetle, striped.
Dialeurodes citri, see Whitefly, citrus.
Diamondback moth—
control, Tex. 78.
rearing, laboratory methods, U.S.D.A. 76.
Diaporthe phaseolorum on pepper fruits, 214.
Diarrhea—
acute, in lambs, control, Mont. 691.
bacillary white, *see* Pullorum disease.

Diarthrothrips coffeae, cause of outbreaks, 378.
Diatraea—
crambidoides, *see* Cornstalk borer, southern.
saccharalis, *see* Sugarcane borer.
Diatrype stigma on oaks, 789.
Dibotryon morbosum, fungi found associated with and life history and culture, 68.
Dibrachoides, feeding habits and condition of ovarian follicles, correlation, 386.
Dicalcium phosphate—
fed to sheep on pingue areas, effect, N.Mex. 87.
production and properties, Tenn. 747.
v. bone meal as mineral supplements for cows, Vt. 834.
Dichomeris marginellus, control, 668.
Diet—*see also* Food *and* Nutrition.
deficiencies in farm families during winter, Wis. 564.
deficiency disease—*see also specific diseases.*
multiple specific nutritional, in adult, 429.
effect on hemoglobin concentration of blood, 423.
healthy, planning, 420.
low cost, for pregnancy and lactation, 421.
of children, *see* Children.
poor in salts when edestin is source of protein, adjustment of rat to, 724.
relation to defective teeth, 890.
relation to rate of growth, 721.
use of banana and milk in for weight control, Mass. 563.
Dietary—
human, long term experiment with rats on, 880.
standards for adult dental patient, 286.
studies, probable accuracy, 417.
surveys, scope, limitations, and applications, 419.
Digonichaeta setipennis, introduction, Idaho 658.
Dilatometer for plant materials, 607.
Dinitrocresol, effects on oxidation and fermentation, 295.
Dinitro-o-cyclohexylphenol in petroleum oil, toxicity of solutions, 225.
Dinitro-ortho-cyclo-hexylphenol for control of citrus red mite, 224.
Diphenylamine for diagnosis of plant troubles, 639.
Diphyllobothrium latum, notes, 709.
Diplodia—
bark disease of lime and lemon, 802.
dry rot of corn, Iowa 55.
natalensis, notes, 788.
root rot of strawberry due to, 788.
salicina on pussy willow, Tex. 57.
spp., notes, Fla. 636.
zeae, culture filtrate, effect on seedling blight of corn, Iowa 361.
zeae, infection with and spread in host tissue, 212.
Diplotriaena tricuspis in crows, 851.
Diprion—
pini, development, effect of ecological factors, 656.
polytomum in Connecticut, Conn.[New Haven] 374, 657.
polytomum, outbreak in 1935 in Quebec, 387.
polytomum, studies, U.S.D.A. 655.
Discussion, group, organization and conducting, Ill. 277.
Disease and parasitism, lectures on, 252.
Diseases—
deficiency, *see* Diet deficiency disease *and specific diseases.*
of animals, *see* Animal diseases *and specific diseases.*
of plants, *see* Plant diseases *and specific host plants.*
relation to insects, 376.
Disonycha camposi n.sp., description, 671.
Dissection dish, four-compartment, U.S.D.A. 76.
Distemper, canine, filtrable virus isolated from, pure cultivation, 848.
Disulfide compounds, determination, 9.
Dithioethylamine substitution for cystine in rat diet, 723.
Dodder attacking olive in California, 482.
Dog tick—
American, survey in Maryland, 540.
brown, vector of piroplasmosis of dogs, P.R. 840.
Dogs—
abnormalities in, inheritance, 609.
Collie, color inheritance in, 32.
variations in rib number and asymmetry of thorax, 192.
young, congenital stenosis of esophagus, 103.
Domestic Allotment Act and soil conservation, Okla. 412.
Dominance
in mice 610.
theories, physiological and evolutionary, 608.
theory, differences with Wright on, 608.
theory, Professor Fisher on, 608.
Doughnuts—
deep fat frying, changes in fat which take place in, Iowa 130.
formulas for frying in deep fat at high altitudes, Wyo. 131.
Dove, new ground, from West Indies, P.R.Col. 75.
Dragonfly name "Odonata", significance, Minn. 663.
Drainage losses under dolomitic lime treatment, Conn.[New Haven] 306.
Drinks, orange-flavored, vitamin C in, Mass. 563.
Drosophila ampelophila, *see* Pomace fly.
Drought—
effect on crops, Nebr. 195.
effect on evergreen trees in Iowa, 351.
effect on nutrient levels in tomatoes, 47.

Drought—Continued.
effect on oak forests, Pa. 352.
effects, measures taken to alleviate, 702.
Droughts—
in United States, U.S.D.A. 789.
of lower Yangtze Valley and predictions, 443.
of 1930–34, 591.
Dry farming—
in Montana, Mont. 860.
in northern New Mexico, N.Mex 37.
Ducklings, day-old, sex differentiation in. 683.
Ducks—
canard, seasonal dimorphism in plumage, 469.
management on small farms, U.S.D.A. 86.
Salmonella infections of, 850.
wild, ecology, Iowa 77.
young, meat scrap and dried milk for, 826; Ind. 820.
Dust—
explosions during fire fighting, U.S.D.A 268.
mixtures containing derris and cube, comparative toxicity, 224.
small quantities, simple hand duster for application, U.S.D.A. 511.
sprays against citrus thrips on oranges, tests, U.S.D.A. 655.
treatise, 4.
Dyes—
azo, fastness to light and washing, effect of position isomerism in, Ohio 572.
azo, fastness to light and washing, factors in, Ohio 431.
natural, home dyeing with, U.S.D.A. 139.
pH concentration and toxicity to fungi, 605.
Dysentery, chronic bacterial, *see* Johne's disease.
Dyslobus spp. on strawberries, Oreg. 232.
Ear tick in Argentina, 85.
Earth, rammed—
age-strength relation, 703.
as structural material, relation to colloids in soil, S.Dak. 703.
for farm buildings, S.Dak. 702.
walls for poultry house construction, S.Dak. 702.
Earthworms—
in soils, effect of low frequency alternating current, N.J. 658.
of Missouri, 805.
Earwig, European, parasite, introduction, Idaho 658.
East coast fever, *see* African coast fever.
Eating utensil sanitation, 417.
Echinostomidae, encystation and development, 104.
Economics, agricultural, *see* Agricultural economics.
Ectoparasites of domestic animals of São Paulo, 840.
Education, agricultural, *see* Agricultural education.
Egg—
albumin, *see* Albumin, egg.
packing plants, two-way candling and grading bench for, 707.
production—*see also* Hens, laying.
breeding for, 324; Mass. 529.
characteristics for estimating, 393.
production, effect of—
artificial heat for pullets during winter months, Mich. 676.
ground soybeans in rations, Del. 532.
inbreeding, Iowa 763.
internal parasites, Wis. 538.
oats in rations, 681.
selection and breeding, Iowa 86.
solutions of ovariolysates, 325.
treatment for internal parasites, 401, 529.
production—
effect on iron in blood of fowls, 828.
efficiency, effect of live weight, Mo. 87.
high, factors affecting, N.Mex. 87.
monthly costs and receipts, N.J. 558.
rate, relation to pauses, 242.
rations for, Fla. 675.
relation to early sexual maturity, Iowa 86.
relation to time of hatching, Mo. 86.
relation to vitamin A and D intake by hen, 242.
seasonal changes in, 680.
value of meat scrap and dried skim milk for, Iowa 86.
yolk and bran as sources of iron in human diet, 883.
yolk membrane, measuring strength of, 680.
yolk, ruptured, studies, N.H. 546.
yolk, vitamin D in, 426.
yolks, color index, 243.
Egg-laying contests, mortality rates in, N.J. 680.
Eggplant—
anthracnose diseases, 788.
bacterial wilt, control, 494.
fresh and pickled in salt, analyses, Hawaii 415.
seeds, storage, 46.
Verticillium wilt, control, N.J. 638.
yellows, effect of sulfur and iron sulfate, Tex. 57.
yellows, notes, Tex. 58.
Eggplants—
floral biology and morphology, 628.
magnesium requirements, Va.Truck, 779.
Eggs—
amino acid content, relation to diet and incidence of chondrodystrophy, 680.
and poultry, Okla. 269.
breaking strength, relation to shell characteristics, 880.

Eggs—Continued.
brown, grading percentages, N.H. 555.
changes in composition during storage, 131.
cooling by different methods on farms, results, 682.
cooling, effect on size of air cell, 682.
for hatching, production, Wis. 243.
from hens on experimental diets, physical properties, Fla. 675.
hatchability—
and eggshell formation, effect of calcium intake levels, R.I. 824.
and size of air cell, relation to relative humidity, Hawaii 388.
effect of internal parasites, Wis. 538.
effect of multiple turning and orienting eggs during incubation, 393.
genetic aspects, 611.
nutritional factor affecting, 392.
relation to size, Mo. 86.
relation to vitamin G complex, Ohio 389.
when inoculated with *Salmonella*, *Pasteurella*, staphylococci, and streptococci, 260.
hatching, seasonal variation in, Mo. 86.
incubation, *see* Incubation.
interior quality, relation to protein supplements, 829.
interior quality, seasonal changes in, 824.
iodine content, Hawaii 415.
laid by one hen, feed purchasing power, Mo. 86.
marketing under U. S. grades, Ind. 819.
of pullets and yearling hens, fertility, 613.
outlook charts, U.S.D.A. 120.
physical characteristics, effect of rations and storage, Iowa 96.
physical quality, factors affecting, S.C. 87.
quality and number, effect of rations, N.Mex. 87.
quality for cake making, measuring, 564.
quality, seasonal variations in, 394, 824.
size and number, factors correlated with 681.
size, methods of measuring, N.J. 680.
storage, Fla. 675.
storage, effect of packing materials on flavor, [N.Y.]Cornell 826.
storage quality, effect of feeds, Tex. 88.
viscosity, external measure, Iowa 394.
weight when grain is hopper-fed, 389.
Eimeria—
faurei, cause of losses of lambs, Colo. 252.
faurei in goats, P.R. 840.
kofoidi n.sp., notes, 403.
miyairii in rats, effect of diet, 253.
miyairii infection, effect of vitamin B and G-deficient diet, 399.
Eimeria—Continued.
miyairii, relation to vitamin G, 840.
tenella, organ specificity, 692.
Electric—
current, intermittent, foot-operated switch for, U.S.D.A. 76.
currents, high frequency alternating, effect on animals, Mich. 691.
fences, use, Idaho 701.
potential of living cell at flux equilibrium, 28.
refrigeration and air conditioning, 734.
steam generator for sterilizing farm dairy utensils, 708.
stills, automatic cut-off for, 439.
water heaters, optimum temperature, Wash. 141.
Electrical phenomena in plants, cause, 456.
Electricity—
applications to small-scale gardening operations in England, 706.
for farm homes, Ind. 409; Me. 431.
in home and on farm, treatise, 116.
in poultry farming, 706.
on farms of Washington, 265.
soil heating with, Ind. 851.
Electrification—
rural, Idaho 701.
rural, survey in New Hampshire, N.H. 549.
rural, treatise, 264.
Electrodes, inert, use in measuring streaming potential, Minn. 582.
Electrokinetics, studies, Minn. 582.
Electrophoresis, streaming potential, and electrosmosis, comparison, Minn. 582.
Elcodes opaca, *see* Wireworm, plains false.
Elevators—
farmers' cooperative grain, membership, financial, and operating status, 869.
in Indiana, local grain, economic analysis, Ind. 124.
Elm—
bark beetle—
native, associated with spread of Dutch elm disease, 231.
smaller European, associated with spread of Dutch elm disease, 231.
bark beetles—
in New York State and *Scolytus sulcatus* on apple, 224.
trap-log studies, 524.
borer, relation to Dutch elm disease, 371.
cedar, twig blight of, Tex. 57.
Cephalosporium wilt, new facts concerning, 803.
disease, Dayton, relation to *Cephalosporium*, 496.
disease, Dutch—
bark beetles as vectors, 231.
control, Conn.[New Haven] 356.
distribution and control, Ohio 357.
dwarf Asiatic species resistant to, 223.
eradication, 231; N.J. 638.

Elm—Continued.
disease, Dutch—continued.
in Connecticut, Conn.[New Haven] 141.
in dead and dying elms, 496.
insect vectors, 231, 371; Mass. 512.
modifications in quarantine regulations, U.S.D.A. 496.
notes, Ohio. 634.
papers on, 371.
summary, 653.
survey, Mass. 497.
lacebug, notes, Conn.[New Haven] 657.
leaf aphid, notes, Conn.[New Haven] 657.
leaf beetle, longevity, 224.
leaf beetle parasite, description, 818.
scale, European, control, Idaho 658.
Siberian or dwarf Asiatic, importance in control of Dutch elm disease, 223.
spanworm, notes, Conn.[New Haven] 657.
trees, death in Czechoslovakia, 656.
Elsinoe ampelina, inoculation of rabbits with, 505.
Emmer v. barley for fattening steers, N.Dak. 529.
Emphysema, intestinal, in swine, 544.
Empoasca—
fabae, *see* Potato leafhopper.
maligna, *see* Apple leafhopper.
spp., notes, 808.
Encephalitis—
in horses, 545; Ind. 840.
in rabbit, inoculability by external auditory canal, 840.
outbreak, insect carriers, 663.
protozoan, of cattle in Uganda, 693.
Encephalomyelitis—
Australian epidemic of, 692.
equine—
Argentine, seat of virus, 848.
Argentine, transmission to birds, 110.
Argentine virus, inoculability by external auditory canal, 848.
status, 101, 258.
symptoms, 401.
transmission of virus through *Aedes* spp., 848.
virus, active immunization of guinea pigs with, 108.
virus, detection, tissue cultures more sensitive method than animal inoculation, 401.
virus infection of Rhesus monkey and guinea pig, 697.
virus, neutralization by immune serum, 107.
in goats, 104.
nonvirus, of horses, 258.
Endocrine glands, relation oestrus cycle, 614.
Endocrinology, experimental, zootechnical problems in, 325.
Engineering Conference, Up-Stream, editorial, 577.
Engines, multicylinder, relation of power to antiknock fuel requirements, 265.
Ennomos subsignarius, *see* Elm spanworm.
Enteritis—
chronic, *see* Johne's disease.
in chickens, intestinal flora associated with, Fla. 547.
Enterohepatitis—
anatomopathological study, 850.
infectious, *see* Blackhead.
Entomological—
events, outstanding, of 1934, 806.
service, organization in Canada, 656.
technic studies, U.S.D.A. 75.
Entomology—*see also* Insects.
American, pioneer century of, 805.
Philippine, historical résumé, 375.
Entomophthora sphaerosperma, parasite of white apple leafhopper, 496, 664.
Enzyme activity of sugarcane, effect of potassium, 437.
Enzymes analysis, importance in agricultural chemistry, 11.
Eperythrozoon—
effect of splenectomy, 543.
ovis in Algeria, 696.
ovis in France, 696.
Ephestia—
elutella, *see* Tobacco moth.
figulilella, notes, U.S.D.A. 511.
kuehniella, *see* Flour moth, Mediterranean.
Epiblema—
prosimana, notes, 656.
tedella, notes, 656.
Epicampoptera moths on coffee, 808.
Epicoccum blight on bulbous iris, control, 652.
Epididymitis, suppurative, in a dog caused by *Brucella abortus*, 849.
Epilachna corrupta, *see* Bean beetle, Mexican.
Epitrix—
cucumeris, *see* Potato flea beetle.
parvula, *see* Tobacco flea beetle.
Erannis tiliaria, *see* Lime tree looper.
Ergosterol—
crystals, powdered, electrophoretic behavior, Minn. 582.
irradiated, and cod-liver oil, antirachitic potency, comparison, 429.
irradiated selectively, studies, 429.
Ergot of grains and grasses, N.Dak. 497.
Eriophyes essigi in Oregon, Oreg. 233.
Eriosoma lanigera, *see* Apple aphid, woolly.
Erosion, *see* Soil erosion.
Erwinia amylovora—
in insects, persistence, 639.
notes, 647.
relation to blossom abscission of pears and apples, 495.
Erysipelothrix rhusiopathiae—
as antigen in swine erysipelas, 848.
in fishes, 103.
Erysiphe polygoni—
diurnal cycle, 642.
host range and physiologic specialization, 642.

Erythrina recticulata n.sp., description, 812
Erythroneura comes, see Grape leafhopper.
Escherichia-Aerobacter group in milk, detection, comparison of test media, 688.
Escherichia coli—
acid production by, Mass. 436.
electrophoretic mobility, effect of electrolytes in growth media, 605.
electrophoretic mobility, effect of X-rays, 605.
in commercial fish and fillets, detection and significance, 720; Mass. 436.
Ethanol in aqueous solution, analysis, 160.
Ethyl alcohol, food value, 725.
Ethylene—
dichloride-carbon tetrachloride and tetrahydronaphthalene as moth fumigants, comparison, 655.
effect on stem growth of tomato plants, 456.
production by fruits and vegetables a natural phenomenon, Minn. 627.
Euchlaena, Tripsacum, and corn, genetic and cytological relations, Tex. 38.
Eucolaspis brunnea, control, 384.
Eucyathostomum longesubulatum from Trinidad deer, 655.
Eudeleboea lopezi, parasite of oriental fruit moth, 815.
Eugenia species, propagation, etiolation shoot method, 50.
Eumerus tuberculatus, see Bulb fly, lesser.
Eupatorium glandulosum, poisonous to cattle, analyses, Hawaii 399.
Euplectrus manilae, identity, 385.
Eurydinota lividicorpus, notes, 668.
Eurytoma n.sp., notes, 386.
Eutelus, feeding habits and condition of ovarian follicles, correlation, 386.
Eutettix tenellus, see Beet leafhopper.
Euthrips gossypii, new name proposed for, 810.
Euxoa, see Cutworms.
Evaporation—
from plants, empirical formula for, 459.
studies, Ohio 312.
studies in southern California, 702.
survey of Ohio, Ohio 443.
Evergreen trees in Iowa, drought susceptibility, 351.
Everlasting, sclerotial stem rot of, 208.
Ewes—*see also* Sheep.
artificial insemination, tests, 822.
breeding, roughage ration for, Mont. 676.
breeding, winter range for, 528.
breeding, winter rations, Mich. 676; Mont. 240.
breeding, wintering, Mont. 676.
effect of size and type on efficiency of production, Md. 91.
plane of nutrition, effect on wool, lamb, and milk production, La. 678.
Rambouillet bred, crutching or tagging, Tex. 88.
rate of sperm travel in, 469; Mass. 466.
Ewes—Continued.
reproductive organs, changes in, 612.
summering on the forest, Mont. 676.
Exanthema, vesicular, of swine, 101.
Experiment stations—*see also* Arkansas, Connecticut, *etc.*
in 1935, editorial, 433.
list of bulletins, 1933 and 1934, U.S. D.A. 141.
report, 575.
Extension—
activities, Ohio 53.
work, relation to regional planning, 268.
Extractors, automatic, use, 6.
Eye defects in rabbits, production and inheritance, 609.
Eye lens, vitamin C in, relation to vitamin B_2 deficiency, 284.
Fabraea maculata, life cycle and control, 495.
Fagopyrum esculentum, embryo development, 762.
Fallow, methods of preparing and cultivating, Mont. 616.
Families—*see also* Farm families.
cost of living of farm, nonfarm, open country, and village groups, Wis. 560.
life cycle, 715.
rural, receiving relief, changes in, Wis. 560.
Family—
finance, economics of consumption, treatise, 891.
living in United States and other countries, U.S.D.A. 140.
relief and rehabilitation possibilities, Wis. 560.
size, relation to homogeneity of parental traits, 716.
Farm—
account records and survey records, Mo. 119.
animals, *see* Livestock *and* Animals.
building losses due to wind and fire, Iowa 111.
buildings, studies, Ind. 863.
buildings, treatise, 857.
business and type-of-farming study, S.C. 120.
contribution to family living expenses, Mo. 119.
credit, *see* Agricultural credit.
Economic Association, American, papers, 268, 554.
Economics Association, Western, proceedings, 268.

seed, variety tests, N.Dak. 474; N.J. 616.
variety tests, Iowa 35; S.C. 37; Tex. 38; Wash. 38.
Flaxseed—
effect of organic mercury dusts, Iowa 55.
feeding value, Colo. 531.
husks v. cottonseed hulls for wintering beef cattle, S.C. 87.
oil in, quantity and quality, N.Dak. 475.
rate of deposition and desaturation of linseed oil in, during seed development, N.Dak. 474.
treatment, 495.
Flea beetles—
effect of Alorco, Tenn. 84.
feeding insecticides to, 659.
Flies—
and fly sprays, effect on physiological processes of cows, 256.
chloropid, of grasslands, 521.

Flies—Continued.
clusters, mistaken for rust patches Conn.[New Haven] 657.
house, *see* Houseflies.
on cattle, dusts for control, 521.
white, *see* Whiteflies(y).
Flood—
control and reclamation, practical aspects, 852.
run-off, relation to rainfall, 12.
water, conservation by spreading, economic limits, 702.
waters for irrigation, storage and use, Mont. 701.
Floods of lower Yangtze Valley and predictions, 443.
Floor—
construction, concrete, precast joist-precast slab, load performance tests, 704.
constructions supported by steel beams, fire resistance and time-temperature curves, 854.
timbers, rotting by *Poria incrassata*, 789.
Flooring, oak, commercial standard CS56–36, 855.
Flora—*see also* Plants *and* Vegetation.
of copper-tailing region, copper in, 180.
of Mount Taylor, palatability and check list, N.Mex. 847.
Florida Citrus Research Laboratory, establishment, 896.
Florida Station, report, 735.
Flour—*see also* Bread.
baking test, N.Dak. 475.
beetle, confused, life history, U.S.D.A. 524.
beetles, fluctuation in population of mills, 80.
beetles, partial revision of genus, key, U.S.D.A. 524.
bleaching, 304.
diastatic activity, Minn. 583; N.Dak 475.
diastatic activity, effect of buffers and type of substrate, 739.
enzymes as related to grade and baking charactertistics, Nebr. 148.
hard red and low-protein soft, blending, N Dak. 475.
mills, fumigation with hydrocyanic acid gas, 663.
mills, insect abundance, factors affecting, 80.
mills, insect infestation, reducing, U S.D.A. 77.
moth, Mediterranean, egg development at various temperatures, 656.
production in United States by States and by sizes of mills, 871.
Flower seeds, quality on sale in New York, 626; N.Y.State 205.
Flower thrips—
Florida, Fla. 658.
on cotton, Tex. 78.
studies, S.C. 78.
Flowers—*see also* Plants, flowering, *and* Plants, ornamental.
cut, keeping quality, effect of nitrogen, Ohio 340.
of Texas in natural colors, treatise, 320.
Flume, Parshall measuring, description, Colo. 551.
Fluorides, ingestion, effect on constituents of bones, Iowa 86.
Fluorine—
and fluorine-silicon salts, injury to plants, 761.
distribution in tissues of laying hens, Wis. 530.
effect in diet, Wis. 530.
effect on basal metabolic rate of rat fed desiccated thyroid, 528.
effect on phosphatase content of plasma, bones, and teeth of rats, 730.
efficiency against apple flea weevil, 673.
in Chinese food materials, 733.
in tissues of laying hen, distribution and storage, 825.
in water, methods for determining, 851.
in water supply, relation to mottled enamel of teeth, 731; Ariz. 732.
relation to bone and teeth development, 733.
studies, Tenn. 884.
toxicosis, chronic, effect of organic dietary constituents, 730.
Flushing, use of term, 529.
Fodder crops, *see* Forage crops.
Folliculin—
benzoate, action on plumage of fowls, 320.
benzoate and ovarian grafts, action on comb and spurs of capons, comparison, 330.
solutions, effect on sexual system in pullets, 325.
Follutein injections, effect, 615.
Fomes—
annosus sport germination and growth, effect of temperature and pH, Ohio 357.
fomentarius on walnuts, 309.
gcotropus causing heart rot of magnolia, 803.
pini, variations in morphology and growth habit, 654.
Food—*see also* Diet.
and nation in Great Britain, 418.
and nutrition, Hawaii 415.
aversion of children and feeding problems, 280.
consumption survey of New York, 534.
fallacies and nutritional quackery, 880.
fat in, unified method for determination, 302.
health and disease in relation to, 419.
health, and income of people of Great Britain, 418, 419.
industries, relation to research, 717.
materials, Chinese, fluorine in, 733.

Food—Continued.
plants, absorption of chemical elements important in human nutrition, Mass. 444.
preference as guide in nutrition studies, Me. 388.
products, acid constituents, 5.
selection, causes and effects of variations in, Me. 389.
supply of Great Britain, effect on public health, 417.
supply of Great Britain, effect on public health, editorial discussions, 419.
values at a glance, 420.
Foods—
canned, *see* Canned foods.
dried, microbiological examination, 278.
dried, micro-organisms on, Mass. 563.
frozen, studies, Mass. 563.
home-grown, relation to anemia, Fla. 717.
iodine in, 567.
lack of vitamin D in, 426.
Philippine, vitamins in, 570.
selenium in proteins, effect of acid hydrolysis, 237.
selenium in, occurrence and nature, 90.
studies, Nebr. 277.
vitamin G value, procedure for determining, Idaho 726.
Foot-and-mouth disease—
sequelae to, 104.
studies, 102.
Forage—
crops, diseases in Delaware, 356.
crops, preservation, effect of trench silo for, Fla. 675.
crops, variety tests, Ga.Coastal Plain 194; N.Mex. 36.
grasses, *see* Grasses.
green, water content, technic for determination, Iowa 85.
plants, insect and other pests, 207.
poisoning, *see* Livestock poisoning, Plants, poisonous, *and specific plants.*
preservation by mineral acids, Ohio 395.
Forages—
from lake water vegetation, Minn. 678.
green, analyses and digestible nutrients, U.S.D.A. 821.
in different sections of State, phosphorus and calcium in, N.Mex. 87.
range, of Colorado, mineral content, Colo. 238.
Forest—
Cloquet, establishment and management, Minn. 634.
fire protection, new devices for, 13.
fires, control, Ohio 353.
influence studies at San Dimas Experimental Forest, 702.
lysimeters, data yielded by, Conn.[New Haven] 306.
News of Ohio, Ohio 634.
nurseries, nematodes affecting, 509.
Forest—Continued.
nursery operation, soil conditions required, Wis. 445.
products, marketing, Ohio 53.
Protection Experiment Station in Prague, parasite rearing by, 656.
regions of United States, U.S.D.A. 205.
soil profiles, Podsol and Brown, studies, 306.
trees, *see* Trees.
Forestry—
early Minnesota, shelterbelt planting revealed in, Minn. 735.
meaning to Ohio Valley, Ohio 53.
technical notes, U.S.D.A. 53.
Forests—
Rocky Mountain, light fuels in, moisture relation to weather, 54.
State, public use policies, Ohio 53.
Forficula auricularia, see Earwig, European.
Formaldehyde—
dust prepared with different carriers, relative stability, Ohio 357.
toxic action on housefly, 521.
Foulbrood—
American, contamination of honey with *Bacillus larvae* spores, 673.
American, resistance to, by some colonies, 818.
American, studies, Ohio 374.
European, unidentified bacillus in larvae affected with this disease, 385.
4-H poultry clubs, manual for, Ill. 716.
Fowl—
Brahma-Plymouth Rock mosaic in, 764.
cholera vaccine, 402.
coryza bacillus, cultural requirements, 110.
mite, northern, life history, habits, and control, 403.
paralysis, *see* Paralysis.
pest and similar diseases of poultry, 102.
pox, egg-propagated virus of, 546.
pox, immunization studies, 403.
pox, prevention with home-made virus, 401.
pox, skin vaccination for, N.H. 546.
pox, studies, 259.
pox, use of pigeon pox virus against, 548.
pox vaccine, efficacy, 698.
pox virus vaccination of day-old chicks, 102, 110.
typhoid, *see* Typhoid, avian.
Fowls—*see also* Chickens, Hens, Poultry, *etc.*
Frizzle, endocrine glands, 618.
Frizzle, weight and size of organs in, [Conn.]Storrs 764.
genetic mosaics in feathers, 469.
genetic studies, [Conn.]Storrs 192.
gizzardectomized and normal, digestibility in, comparison, 827.
hybrid between Japanese Long-tailed and White Leghorn, precipitation test for, 192.
nutritional deficiency diseases, Me. 388.

Fowls—Continued.
sex differentiation in feathering, relation to sex glands, 469.
tuberculous, cellular elements and hemoglobin in blood, 700.
Fox Ranch, Experimental, report, 372.
Foxes, silver, reproduction under influence of sex stimulators, 325.
Francis, M., pioneer in experiment station research in veterinary medicine, editorial, 578.
Frankfurters, spoilage and restaurant sanitation, Mich. 720.
Frankliniella—
cephalica bispinosa, notes, Fla. 658.
fusca, *see* Tobacco thrips.
gossypiana, new name proposed for *Euthrips gossypii*, 810.
tritici, *see* Flower thrips.
Freezer lockers, development and uses for preserving fresh meat, U.S.D.A. 821.
Frost—
damage in May 1935 in Great Britain, 13.
damage to crops in India, January 1934, 12.
resistance in perennial plants, 313.
resistance of fruit trees, 343.
rings, formation in winter-injured trees and shrubs, 313.
risks and frost forecasting, 13.
susceptibility to and polyploidy, 322.
Frosts, spring, response of crops to, 313.
Fructose—
and galactose, intermediary metabolism, 567.
determination in fruits, 878.
injections into cows, effect on blood sugar and lactose in milk, 832.
Fruit—
beetle, dried, in pineapple fields, biological studies, 384.
brown rot and associated diseases, 221.
bud formation, N H. 443.
diseases in New South Wales, 358.
diseases in 1935, 709.
farms in Great Britain, frost damage in May 1935, 13.
insects, biological control, Idaho 658.
juice concentrates, low-cost production from surplus and cull fruits, Idaho 626.
juices and grape juice, comparative effect on urinary acidity and excretion of organic acids, 416.
moth, oriental—
bait solutions for, 376.
biology, injury and Argentine parasites, 815.
control, Conn.[New Haven] 374; Ind. 806.
latest methods of fighting, 808.
notes, Ohio 374.
parasite, mass liberation, 525.
parasites, introduction in peach orchards, Mass. 512.
studies, Ohio 814; S.C. 78.
Fruit—Continued.
plants, effect of fertilizer limitation, Mass. 483.
stocks under study at experiment stations, U.S D.A. 486.
tree chlorosis, control by internal administration of iron salts, 220.
tree diseases, 208.
tree leaf roller, larvicides for control, 668.
tree leaf roller, notes, Conn.[New Haven] 658.
tree little-leaf or rosette, studies, 709.
tree rootstocks, notes, N.Y.State 48.
trees and soil, water in, interrelation, Ohio 340.
trees, frost resistance of, 343.
trees, nitrogen fertilization, Mo. 343.
trees, spraying, Mo. 44.
trees, winter injury to, Wash. 45
Fruitflies—
autecology, 816.
control with white oil-nicotine sulfate spray, 816.
economic importance in South India, 79.
heavy infestation on Bombay mangoes, 806.
Key West eradication project, 228.
supercooling death, 809.
West Indian, at Key West, hosts and reaction to sprays, 522.
West Indian, effect of low temperature in Peru, 383.
Fruits—*see also* Orchards, Apples, Peaches, *etc.*
adaptability, Tex. 45.
analyses and digestible nutrients, U.S.D.A. 821.
annonaceous, propagation, Hawaii, 339.
available carbohydrate of, 878.
breeding, N.Dak. 483.
breeding and cytology, N.Y.State 191, 608.
carlot shipments from stations in United States, U.S.D.A. 276.
citrus, *see* Citrus.
cropping in 1934 and 1935, N.Mex. 45.
cull, definitions, 483.
dried, insects affecting, U.S.D.A. 655.
dried, micro-organisms in, Mass. 436.
dried sulfured and unsulfured, vitamins retained in, 282.
ethylene production in ripening and blanching, Minn. 627.
Florida, unusual constituents of ash, composition, Fla. 717.
fresh, precooling in refrigerator cars, Ind. 851.
grading, research as basis, 554.
hardiness tests, Fla. 626.
insects affecting, 808.
losses in market and kitchen due to diseases, U.S.D.A. 55.
marketing agreements, 208.
marketing, research in and need for, 554.
mylases of, 816.
new Minnesota, characteristics, 48.

Fruits—Continued.
new, testing, Idaho 626.
of Hawaii, composition, nutritive value, and use, Hawaii 879.
of Philippines, vitamins in, 570.
orchard, for Iowa, Iowa 48.
outlook charts, U.S.D.A. 120.
preservation by freezing, Oreg. 719.
processing by electricity, 265.
propagation, etiolation shoot method, 50.
received in trucks in Columbus wholesale market, 870.
shrivelling, 628.
small, breeding, Tex. 45.
small, culture and varieties, Miss. 340.
small, diseases in Delaware, 356.
small, diseases in western New York, 365.
small, variety tests, N.J. 627; R.I. 779.
small, winter injury, N.J. 627.
spray residue on, N.Mex. 78.
spray residue removal from, Wash. 45.
spraying directions, Ill. 201.
spraying program and pest control, Ohio 201.
stone, brown rot control, 650.
stone, diseases in western New York, 365.
stone, timing of sprays for fungus diseases, 650.
storage in carbon dioxide, warning note, 486.
storage in caves, 486.
tests, Alaska Col. 778.
tree characters, Mass. 483.
truck transportation in western Maryland, 870.
varieties, Fla. 626; Mass. 483.
variety tests, Fla. 626; Ga.Coastal Plain 197; Tenn. 779; Tex. 45.
winter and freezing injury in Illinois, U.S.D.A. 496.
yield and cost of growing and harvesting, N.Mex. 120.
Fuels, Diesel, cetane rating, 856.
Fumigation, industrial, against insects, U.S.D.A. 80.
Fungi—
action on corn byproducts, fermentation products, Iowa 24.
and their diseases, noteworthy species, 789.
blue-staining, associated with bark beetles, 709.
causing diseases in Ceylon, 208.
from Colombia, 208.
growth on liquid media, oxidation-reduction potentials in relation to, 456.
herbarium, progress with, Mont. 638.
in Iowa soils, Iowa 15.
nutritive value, 566.
of Alaska, U.S.D.A. 356.
parasitic, lytical action of soil bacteria, 498.
Fungi—Continued.
pH concentration and toxicity of dyes to, 605.
phytopathogenic, specialization and variation in, 790.
relation to larval development of *Eumerus tuberculatus*, 382.
relation to wireworms, Me. 817.
sclerote-forming, causing diseases of flowering plants, 369.
soil, control by fumigation with chloropicrin, 638.
southern Appalachian, 790.
Fungicides—*see also* Sprays *and specific kinds.*
analyses, Me. 198.
copper, *see* Copper.
dust, development and testing for seed-borne diseases of cereals, Iowa 55.
for citrus fruits, comparison, Fla. 637.
relative efficiency, 356.
Fur-bearing animals of Alaska—
laws and regulations, summary, U.S.D.A. 654.
regulations concerning, amendments, U.S.D.A. 509.
Furfural—
and its emulsions, herbicidal and fungicidal properties, Iowa 35.
petroleum combinations, effectiveness against noxious weeds, 777.
Fusarium—
bulb rot of narcissus, 370.
Culmorum, cause of cereal root rot, 58.
lateritium fructigenum, notes, 494.
lysing bacteria in soil, 498.
moniliforme, entry into growing corn ears, 495.
moniliforme, notes, 494.
nivcum, notes, Fla. 67.
nivcum, relation to wilt-resistant varieties of watermelons, Iowa 364.
niveum wilt of watermelons, Fla. 636.
oxysporum, notes, Fla. 636.
oxysporum, toxicity of dyes to, 606.
sp., effect of chloropicrin as soil fumigant, 638.
sp., isolation from black knots, 68.
spp. on carnations, 370.
spp. on gladiolus, U.S.D.A. 55.
spp., wound parasitism, 353.
toxic principle causing potato wilt, 363.
vasinfectum, growth, effect of temperature, 501.
vasinfectum, insects possible distributing agents, 373.
wilt of chrysanthemums, control, 652.
wilt of cotton, 787, 788.
wilt of okra, seeds as carriers, 788.
wilt of tomato, control, Fla. 636.
wilt of tomato, seeds as possible carriers, Tex. 57.
wilt of watermelon, seeds as carriers, 788; Tex. 57.

Fusarium—Continued.
wilt resistant varieties of tomatoes, Ill. 201.
wilt resistant variety of cowpea, 495.
Fusicladium dendriticum, see Apple scab.
Gaertner bacilli, immunization experiments with, 397.
Galactin in blood of animals in different phases of reproductive cycle, Mo. 35.
Galactose and fructose, intermediary metabolism, 567.
d-Galacturonic acid, derivatives, 149.
Galerucella xanthomelaena, see Elm leaf beetle.
Galleria mellonella, see Wax moth.
Game animals of Alaska, regulations concerning, amendments, U.S.D.A. 509.
Game of Alaska, laws and regulations, summary, U.S D.A. 654.
Ganoderma lucidum on areca and coconut palms, biology, 505.
Garbage, feeding value for growing and fattening pigs, 527.
Garden beetle, Asiatic, biology and control, 522.
Garden, four seasons in, treatise, 482.
Garden insects, *see* Insects.
Gardenia—
Phomopsis canker and gall disease, 652.
Phomopsis canker in Nebraska, U.S D.A. 356.
Gardenias—
propagation and factors affecting growth, Mass. 483.
response to certain stimuli, Mass. 483.
Gardening in England, use of electricity, 706.
Gardens—
home vegetable, in delta area, Miss 779.
vegetable, soil improvement with hairy vetch, Mo. 44.
Garlic, antiseptic action, 255.
Gas—
analysis, improved slow-combustion pipet for, 152.
gangrene, studies, 252.
injury to plants and flowers in greenhouses, 188.
Gasoline—
and mixtures as motor fuels under different road conditions, 405.
extract of wheat, nature of pigments, Minn. 583.
Gasterella lutophila n.g and sp, description and illustration, 209.
Gastric juice of man, effect of vitamin B-deficient diet, 571.
Gastrophilus larvae, migrations and pathogenesis, 692.
Geese—
experimental moulting, 325.
management on small farms, U.S.D.A. 86.
plucking of feathers and down aided by hyperthyroidization method, 326.
Salmonella infections of, 850.
Gelatin—
solutions, viscosity and gel strength, effect of high initial aging temperatures, Mass. 534.
structure, 296.
utilization by rats, 280.
Gelechia gossypiella, see Bollworm, pink.
Gelis sp., notes, 386.
Genes—
behavior in interspecific crosses, 191.
lethal in Jersey cattle, 32.
Genetics, research at Institute of Animal Breeding and Animal Genetics of Friedrich-Wilhelm University, 467.
Geoderces sp. on strawberries, Oreg. 232.
Geology and mineral resources of Kentucky, survey, 270.
Geometrid moth, white, notes, Conn.[New Haven] 657.
Georgia—
Coastal Plain Station, report, 286.
Station, notes, 287.
University, notes, 894.
Geraniol, grades, attractiveness to Japanese beetle, U.S.D.A. 84.
Geraniums, propagation studies, Mass. 483.
Germ plasm, superior, securing in dairy cattle, Mont. 684.
Gibberella saubinetii, toxicity of dyes to, 606.
Ginger treatment with mercuric chloride for control of soft rot, 208.
Girls—
college freshman, clothing costs, 734.
wardrobes of, 575.
Gizzards, removal from fowls, digestion trials, 827.
Gladiolus—
chromosome number in, 31.
corms, small, shortening rest period, 52.
culture and winter forcing, R.I. 52.
disease, control, Iowa 55.
Fusarium spp. on, U.S.D A. 55.
thrips, cold storage as control, 516.
thrips, control, Mass. 512.
thrips, emergency studies, Iowa 77.
thrips, losses from, 810.
thrips, notes, Fla., 658; Ohio 374.
varieties for forcing, Ohio 340.
winter forcing, R.I. 779.
Glanders, susceptibility of mouse to, 104.
Glass aerators, sintered Pyrex, preparation, 607.
Globocephalus spp, notes, 400.
Gloeosporium—
caulivorum on *Trifolium pratense,* U.S. D.A. 496.
on dewberry, N.J. 638.
strains causing cotton anthracnoses, 207.
Glomerella gossypii, laboratory tests, S.C. 56.
Glottidium vesicarium, poisonous to livestock in Florida, Fla. 690.
Glucose—
determination in fruits, 878.
fat formation from, 422.

Glucose—Continued.
fatty acids formation from, 294.
fermentation by *Lactobacillus lycopersici*, diversion by addition of hydrogen acceptors, 606.
ingestion, blood changes following, 241.
injection into cows, effect on blood sugar and lactose in milk, 832.
Glutamine—
in tomato plants, Conn.[New Haven] 293.
metabolism of beets, 760.
Glutathione—
cystinyldiglycine and benzylcysteinylglycine isolation from, synthesis, 436.
effect of X-rays on, 149.
interfering action in silver nitrate test for ascorbic acid, 588.
Glutelins, cereal, preparation and study, Nebr. 148.
Glycerin and boric acid dressings for fly-struck sheep, 400.
Glycine, determination in proteins, 159.
Gnathostoma hispidum, notes, 400
Gnorimoschema—
lycopersicella, *see* Tomato pinworm.
operculella, *see* Potato tuber worm.
Goat lice, studies, Tex. 78.
Goat pox, studies, 102.
Goats—
Angora, utilization of kid skins, Tex. 88.
development of mammary glands, Mo. 764.
genetic studies, Tex. 32.
improvement by breeding, N.Mex. 98.
milk, industry, present status, N.Y.State 686.
milk, management on small farms, U.S.D.A. 86.
nutrition, N.H. 529.
producing oestrum during anoestrum period, Ohio 395.
reproduction in, physiology, Mo. 33.
sterility in, relation to vitamin E, Iowa 97.
Toggenburg, milk production, effect of early breeding, N.Mex. 833.
Goiter regions, iodine content of soils and vegetables grown thereon, 567.
Gonad stimulators, comparative physiological activity, 325.
Gonadotropic—
hormone, determination, improved method, 614.
hormone of mare, age and qualitative ovarian response of immature rat to, 327.
substances, augmenting ovarian response to, 328.
Gonads—
and adrenal cortical hormone, alleged interrelation, 614.
and vitamin E, 766.
development and anterior lobe of hypophysis, 469.
Gongylonema pulchrum, early developmental stages, U.S.D.A. 107.
Gooseberries, spray schedules for, Ohio 201.
Gooseberry—
anthracnose due to *Pseudopeziza ribis*, 503.
fruitworm, outbreak and control, 224.
Goplana dioscoreae n.comb., notes, 209.
Gossyparia spuria, *see* Elm scale, European.
Gossypol, toxicity, effect of calcium carbonate and sodium bicarbonate, 238.
Goulac, value as bait solution, 376.
Governmental functions, financing, relative ability of Tennessee counties, 863.
Grafting wax, testing, Ohio 340.
Grain—*see also* Cereals *and* Oats, Rye, Wheat, *etc.*
and products, analyses and digestible nutrients, U.S.D.A. 821.
and roughage v. grain alone for milk cows, Nebr. 243.
bins, empty, killing insects in, Minn. 663.
drying, Ind. 851.
effect of phosphatic fertilizers, Mont. 453.
feeding, effect on color of beef, W.Va. 822.
Iowa feed, moving from surplus to deficit areas, freight costs, Iowa 123.
nursery equipment, 706.
small, benefits of fallow on dry land, Mont. 616.
small, diseases, 789.
small, varietal resistance to spring frost injury, 617.
smuts—*see also* Cereal smuts *and specific grains*.
control, Mo. 56.
stored, insects affecting, 807.
unground v. ground, feeding value, Tex. 98.
Gram blight, life history and control in Punjab, 362.
Gram wilts in Central Provinces of India, 362.
Granary weevil, experimental control, 657.
Grape—
and other fruit juices, comparative effect on urinary acidity and excretion of organic acids, 416.
berry moth, life history, habits, and control, Del. 517.
black rot, control, 788.
chlorosis in Concords, control, N.Mex. 56.
court-noué disease, 222.
diseases in Florida, control, Fla. 637.
diseases in western New York, 365.
diseases, notes, 799.
diseases, spraying experiments for, Fla. 504.
fruit rots, Fla. 637.
juice, pasteurized at lower temperature, N.Y.State 11.
leafhopper, control, 516.

Grape—Continued.
leafhopper, life history, habits, and control, Del. 516.
leafhopper on Virginia creeper in Montana, Mont. 518.
leaves, absorption of water by, 486.
rootstock resistance tests against *Phymatotrichum omnivorum*, Tex. 57, 58.
Grapefruit—
changes in composition of rind, 631.
cold storage studies, Fla. 626.
harvesting method to retard stem-end rot, U.S.D.A. 802.
refuse, dried, digestibility coefficients and feeding value, Fla. 683.
storage diseases, 506.
Grapes—*see also* Vineyards.
American and hybrid, pruning and training, Idaho 490.
breeding, Tex. 45.
breeding for hardy seedless varieties, N.Y.State 204.
culture in Colorado, Colo. 204.
culture in Kansas, Kans. 204.
fertilizer requirements, R.I. 779.
Isabella, composition, nutritive value, and use, Hawaii 879.
Muscadine, bearing, relation to male vines, 627.
nitrogen fertilization, Mo. 45.
Panariti, seeded mutation of, 31.
physiological and chemical studies, 627
pruning, Iowa 44.
relative absorption of N, P, and K by, Mo. 45.
rootstocks for, Tex. 45.
seedlessness in, N.Y.State 348.
spray schedules for, Ohio 201.
Thompson seedless, vitamins in, 281.
varieties, Tex. 45.
variety tests, Ga.Coastal Plain 197; La. 483; S.C. 45.
winter injury, N.J. 627.
Graphite, effect on friction in drilling dusted seed, 494; N.Y.State 266.
Graphium ulmi, see Ceratostomella ulmi.
Graphocephala—
n.sp., notes, 379.
versuta, studies, S.C. 78.
Grapholitha molesta, see Fruit moth, oriental.
Grasses—*see also* Grasslands, Lawns, Meadows, Pastures, *etc.*
adaptation for range improvement, N.Mex. 37.
and cereals as companion crops, competition, Wash. 38.
breeding, Wash. 38.
breeding and pasture laboratory under Bankhead-Jones Act, 3.
composition, effect of fertilizers, Wis. 475.
composition, relation to growth and maturity, Fla. 615.
dry cured, losses by weathering, N.Dak. 475.
effect of periodic clipping, 767.
Grasses—Continued.
effect on color of beef, W.Va. 822.
English pasture, introduction into Missouri, Mo. 36.
for hay and pasture tests, Iowa 35.
forage, adaptation studies, Hawaii 330.
forage, and mixtures, variety tests, Wyo. 39.
forage, new and improved strains, tests, Wash. 38.
improved, for regrassing cultivated dry land areas by reseeding, Mont. 616.
in New South Wales, fungi associated with root rots of, 59.
lawn and turf, fertilizer experiments, R.I. 767.
lawn and turf, variety tests, R.I. 767.
mixture, sowing on bluegrass and Bermuda sod, Tenn. 767.
of United States, genera, U.S.D.A. 767.
pasture
adaptation and propagation, S.C. 37.
and forage, variety tests, Fla. 615.
and lawn, variety tests, Alaska Col 766.
carotene content, Idaho 676.
carrying capacity, Idaho 676.
chloropid populations on, 521.
composition and yield, effect of nitrogen fertilization and frequency of clipping, 473.
cutting for soiling and silage, Mont. 684.
effects of different rates and carriers of nitrogen, Fla. 615.
fertilizer experiments, 473.
for grazing purposes, comparison, 473.
for western Kansas, 36.
value alone and in mixture, Fla. 231
variety tests, Ga.Coastal Plain 194; S.C. 37; Tex. 38.
propagation for possible erosion control value, Iowa 53.
seasonal growth habits, modifying, [Conn.]Storrs 618.
species and varieties for pasture, [Conn.] Storrs 332.
turf, on lawns, parks, and recreation fields, feeding, N.J. 619.
varieties, hay from, quality, Ohio 389.
variety tests, Idaho 616; Tex. 38.
yield for ensiling from timothy sod treated with calcium cyanamide, N.J. 684.
Grasshopper—
bait, Wisconsin, use without danger to chickens or to persons eating chickens or eggs, Wis. 513.
clear-winged, in California, 515.
nymphs, counting, method, U.S.D.A. 75.
outbreaks, control, 376.
outbreaks, prediction, Mont. 658.
two-striped, laboratory breeding, 806.

Grasshoppers—
control, Colo. 224; Idaho 658; Mich. 658; Nebr. 224.
cyrtacanthacrine, life history and control, S.Dak. 659.
injurious, studies, Iowa 77.
migratory, control, 377.
migratory, outbreaks, 810.
nematode parasite of, life history, 234.
notes, N.Dak. 512.
(red locust), life history, 377.
Grassland Congress, International, notes, 288.
Grazing—*see also* Range.
crops for fattening pigs fed corn and tankage, comparison, Tenn. 820.
sandhill, problems, 474.
Green bottle fly, persistence of *Erwinia amylovora* in, 639.
Green manure—
crop diseases, 208.
for various crops, Tex. 32
studies, Fla. 615.
Green manuring, effect on crop growth in Everglades peat, 451.
Greenhouse
crops, insects affecting, biology and control, 807.
heater, Chatham, description, Mich. 266.
leaf tier, rearing, laboratory methods, U.S.D.A. 76.
thrips, control with naphthalene, Mass 225.
wires and pipes galvanized with zinc, effect of sulfur dioxide, 791.
Greenhouses—
disinfection, Mass. 496.
supplemental lighting, Ohio 44.
Grifola, new combinations and one new form, 354.
Grimmia montana, photosynthesis in, 181.
Grouse, ruffed, disease studies, Mass. 537.
Growth—
essential, unknown, dual nature, 722.
rate and length of life, 134.
rate, relation to diet, 721.
substances, accessory, relation to heavy metals, 462.
substances, use in propagation of plants from cuttings, 318.
Gryllus—
assimilis, see Cricket, field.
domesticus, see Cricket, house.
Guava diseases in British Guiana, 357.
Guavas—
composition, nutritive value, and use, Hawaii 879.
propagation, etiolation shoot method, 50.
Guignardia bidwellii, control, 788.
Guinea pigs—
and rats, development of gonadotropic response, similarity, 766.
hair growth in, factors affecting, 764.
male, lactation in, 614.
nutritional requirements, Mo. 131.
polydactylous, types, 609.
Guinea pigs—Continued.
rosette pattern in, genetics, 191.
susceptibility to rabbit pox virus, 398.
tuberculous Shwartzman's phenomenon in, 103.
vitamin C in organs, effects of experimental diets, 729.
vitamen C requirement, 285.
Gullies, control in southeast, 473.
Gum yield in forests of northern Florida, relation to weather data, U.S.D.A. 635.
Gymnoconia interstitialis infections of *Rubus*, role of intracellular mycelium in, 221.
Gymnosporangium—
germinale, notes, 366.
globosum, biology, 353.
globosum on hawthorn, 789.
juniperi-virginianae, control, Mass. 497.
juniperi-virginianae, notes, 365, 366.
spp. on apples in Hudson Valley, 803.
Gypsum, use for amelioration of slick spots in soils, Idaho 591.
Gypsy moth—
control, Conn.[New Haven] 657.
hibernation, causes, 656.
Habrocytus n.sp., notes, 668.
Haddock meal, nutritive value, effect of manufacturing process, 236.
Haemaphysalis leporis-palustris, see Rabbit tick.
Haematuria, enzootic bovine, etiology, 104.
Haemoproteus genus, check list and host index, 254.
Hail damage to corn, Iowa 770.
Hairlessness, two types in Norway rat, 610.
Hairs, development on plants, effect of nutrition factors on, 461.
Hairy root—
bacteria, nitrogen metabolism, Wis. 497.
effect on apple orchards, 788.
effect on death rate of trees in test orchard, 220.
Halibut, vitamin D in, 426.
Halides, volumetric determinations, 154.
Halogens in organic compounds, semimicro determination, 154.
Ham—
composition, relation to type of hog, 528.
curing, distribution of salt, 241.
salt content, effect of length of time in brine, 529.
Hamster, biology, 373.
Haplogonatopus vitiensis, parasite of sugarcane leafhopper, Hawaii.Sugar Planters' 664.
Haplosphaeria deformans, notes, U.S.D.A. 780.
Haplothrips victoriensis, immature stages, rate of development, effect of temperature, 377.
Haptoncus ocularis in pineapple fields, biological studies, 384.
Hardwoods of the South, properties, U.S.D.A. 704.
Hare, wild, chinchilla mutation in, 609.
Harlequin bug, control, Tex. 78.
Harmostomum suis n.sp., description, 401.

Harvesting equipment, field ensilage, Ind. 851.
Hawaii—
Station, notes, 576.
Station, report, 431.
Sugar Planters' Station, notes, 142.
Hawk, broad-winged, Puerto Rican form, P.R.Col. 75.
Hawthorn, *Gymnosporangium globosum* on, 789.
Hay—*see also specific kinds.*
analyses and digestible nutrients, U.S.D.A. 821.
and haying methods for Upper Peninsula, Mich. 768.
chopped, keeping qualities and storage value, Wis. 535.
crops, annual, variety tests, N.J. 616.
curing, [Conn.]Storrs 243.
drying, Ind. 851.
fertilizer experiments, Alaska Col. 766.
field curing, effect of plant physiological reactions, 409, 472.
from different grasses, quality, Ohio 389.
grass, nitrogen top-dressing experiments, N.H. 474.
home-grown, nutritive value, Wash. 98.
making operation costs, Alaska Col. 766.
making with windrow baler, Minn. 735.
mountain meadow, vitamins in, Colo. 238.
on neglected hay lands, N.H. 474.
outlook charts, U.S.D.A. 120.
palatability, Wyo. 99.
time of cutting test, N.H. 474.
Health—
public, and nutrition, 132.
public, effect of national food supply of Great Britain, 417.
public, program, role of veterinarian in, 101.
service in secondary schools of Idaho, Idaho 716.
Heart—
beef, nutritive value after heating and after alcohol extraction, 877.
fibroblasts, proliferation, effect of vitamin A, 425.
Heat—*see also* Temperature.
textbook, 266.
Heater—
Chatham, for small sash greenhouse, description, Mich. 266.
electric, for use in evaporation of concentrated salt solutions, 153.
Heating and air conditioning, treatise, 267.
Hebin—
daily injections, effect on development of sexual characters in chicks, 469.
from pregnant urine administered after hypophysectomy, effect, 765.
Hegari fodder, effect on cows and on vitamin A in butterfat, N.Mex. 98.
Heifers—*see also* Cows.
birth and mature weight, effect of type of sire, Mont. 676.
Heifers—Continued.
dairy, winter feeding methods, relation to growth on summer pasture, N.J. 684.
finishing after a wintering ration, Nebr. 239.
full v. light winter rations, Mont. 676.
legume hay and cracked corn for, Ind. 830.
range, effect of winter ration, Nebr. 239.
yearling, wintering, digester tankage v. cottonseed meal for, Fla. 675.
Heliothis obsoleta, see Bellworm *and* Corn earworm.
Heliothrips haemorrhoidalis, see Greenhouse thrips.
Hellula undalis, see Cabbage webworm.
Helminth parasites in cattle in Lahore, 104.
Helminths of Kwangtung pigs, 400.
Helminthosporium—
gossypii, notes, 207.
oryzae, notes, 787
sativum, cause of cereal root rot, 58.
sp. isolated from a Hereford cow, 695.
sp. on corn, seed transmission, 213.
spp., physiologic specialization in, 59.
torulosum, notes, 208.
variants in, relation to heterocaryosis, 404.
Hemerocallis roots, *Rhizoctonia* decay of Tex. 57.
Hemicellulose—
from oat hulls, 294.
in alfalfa roots, 740
in plants, analysis, 742.
Hemicrepidius decoloratus, notes, Me. 817.
Hemiteles—
tenellus, notes, 668.
venturi, parasite of oriental fruit moth, 815.
Hemlock sawfly, western, biology, 819.
Hemoglobin—
concentration of blood, effect of diet, 423.
formation, banana as source of iron for, 725.
in blood of laying hens, 391.
level among London mothers of hospital class, 135.
regulation in chickens, 391.
Hemophilus gallinarum—
isolation, technic for, and reaction of chickens to extranasal inoculations, 547.
notes, 259.
proposed name, 110.
relation to coryza of poultry, R.I. 849.
Hemorrhagic—
chick disease of dietary origin, 96.
septicemia, *see* Septicemia.
Hemp—
manila, *see* Abaca.
production surveys, Wis. 475.
production tests, Miss. 331.
Hendersonula morbosa, isolation from black knots, 68.

Hens—
age, relation to reproductive ability and viability of progeny, 610.
force-molting effect, Oreg. 827.
hyperthyroidization in, relation to nutritive rations, 325.
in individual cages, production records, N.J. 680.
laying—*see also* Egg production.
ability in battery brooders, stimulating, 325.
artificial illumination for, Hawaii 388.
barley v. corn in ration for, N Dak 530.
calcium metabolism of, 825.
cod-liver oil in diet, effect on embryo mortality and on calcium and phosphorus content, Ky. 825.
controlling mortality in flocks, 401.
hemoglobin content of blood, 391
management in cages, 682.
vitamin A content of livers, 390.
vitamin A requirements, Idaho 676.
nutrition studies, S.C. 87.
secretory activity of parts of oviduct, 824.
Hepatoflavin—
and pernicious anemia, 889.
preparation and nutritional value, 889
Hepialus pharus, studies, Hawaii.Sugar Planters' 82.
Herbicides, sulfuric acid and sodium chlorate as, Me. 330.
Herd improvement studies in Florida, 528.
Heredity—
in corn, S.Dak. 769.
in wheat, Wash. 30.
of a lethal condition in Jersey cattle, 32.
of abnormalities in dogs, 609.
of bean mosaic resistance, 793.
of color, *see* Color inheritance.
of doubleness in flowers of naturtium, 31.
of flatfoot in horses, 467.
of jointless pedicel in tomatoes, 31.
of natural immunity in plants, 465.
of oat covered smut resistance, 607.
of productivity in farm animals, 323.
of seedling stem color in broomcorn and sorghum cross, 608.
of skin defect in cattle, 32.
of tobacco root rot resistance, 646.
of tree shape in apple progenies, 487.
of tuberculosis susceptibility in cattle, 324.
of wool characters in sheep, 762.
Hernia and crest in fowls due to single gene, 468.
Herpes, inoculability by external auditory canal, 841.
Herpetology, problems in, 375.
Hesperethusa crenulata, citrus scab affecting, 368.
Hession fly—
infestation and wheat culm characters, 775.
Hession fly—Continued.
mass rearing cages, U.S.D.A. 76.
resistance, inheritance in wheat crosses, 670.
studies, Nebr. 224.
Heteroauxin and auxin-a, different action, 318.
Heterodera—
marioni, *see* Root knot nematode.
radicicola, *see* Nematodes.
schachtii, host plants, U.S.D.A. 55.
Heteroderes laurentii, *see* Wireworm, gulf.
Heterospilus coffeicola, parasite of coffee berry borer, biology, 818.
Heterosporium leaf spots on bulbous iris, control, 652.
Hexamermis sp., parasite of wheat wireworm, Me. 818.
Hickory, seedling production, 633.
Highways, *see* Roads.
Hippelates pallipes, yaws transmitted from man to rabbits by, 816.
Hippodamia convergens, *see* Ladybeetle, convergent.
Histomonas melleagridis, notes, Md. 849.
Hitches—
technical specifications for, S.Dak. 406.
wagon and trailer, Iowa 111.
Hog cholera—
East African, studies, 102.
haemacytological changes in, 103.
studies, 252.
Hogs, *see* Pigs *and* Swine.
Holanusomyia pulchripennis, identity, 385.
Holocera iceryaella, control with cryolite, 230.
Homalodisca n.sp., notes, 379.
Home economics, world progress in, 563.
Homemaking—
educational program for, consumer-buying in, 563.
instruction, space and equipment for in vocational teaching, 562.
Homocystine, synthesis, 293.
Homoeosoma electellum injury to sunflowers in Manitoba, 815.
Honey—
and some of its uses, U.S.D.A. 132.
of Iowa, granulation and cloudiness, Iowa 4.
plants, relation to insects, Tex. 78.
production, meteorological factors in, Iowa 77.
transmission of nectar into, factors involved, Iowa 77.
Hop—
chlorotic disease, seed transmission, 362.
diseases on Pacific coast, U.S.D.A. 55.
downy mildew, 496.
mildews, limiting factors for production in New York State, N.Y.State 214.
Hoplocampa—
flava, control, 387.
testudinea, studies, 807

Hops-
production and prices in New York and other areas, N.Y.State 127.
production surveys, Wis. 475.
quality in, N.Y.State 200.
Hormones—
effect on plant growth, 185.
male, female bitterling as test for, 470.
relation to root formation on stem cuttings, 186.
Horn fly, attempted transmission of anaplasmosis by, 810.
Horse—
diseases, survey, [Conn.]Storrs 252.
teams, large, field machinery hitches for, S Dak. 702.
Horsefly, black, attempted transmission of anaplasmosis by, 840.
Horsemint for honey and oil production, Tex. 78.
Horseradish tests, Alaska Col. 778.
Horses—
and tractors on Aroostook potato farms, cost of maintaining, Me. 411.
blood group properties and inheritance. 191.
economical pastures for, 528.
energy expense of working in, Mo. 87.
flatfoot in, inheritance, 467.
fundamental economics, 528.
nutrition, N.H. 529.
of different ages and body weights, horizontal walking, energy expense, Mo. 87.
parasite control, Mich. 691.
production, readjustment to diversified farm, 528.
twin production in, inheritance of tendency, 467.
variations in rib number and asymmetry of thorax, 192.
Horsesickness, 545.
Horticultural activities at Ohio Experiment Station, Ohio 627.
Hotbed heating unit, inexpensive and easily built, U.S.D.A. 76.
Hotbeds, electric, construction, Ohio 340.
Houseflies—
breeding habits in Hungary, 382.
control, Iowa 816.
dosage-mortality curve of pyrethrum sprays on, 671.
effect of formaldehyde, 521.
kerosene-base insecticides for, method for testing, U.S.D.A. 75.
persistence of *Erwinia amylovora* in, 639.
sensitivity to sucrose, effect of inorganic salts on, Iowa 77.
tarsal chemoreceptor response to sucrose and levulose, 382.
Household equipment studies, Iowa 140; Nebr. 286.
Housekeeping activities in home of married women on full-time outside occupations, R.I. 892.
Human welfare, relation to botany, 312.
Humidity—
control cabinets, description, 769.
recording among leaves of plants, device for, U.S.D.A. 76.
Humus, formation—
and decomposition of organic matter in soils, Iowa 15.
mechanism, N.J. 592.
Hyacinth bulbs, production, N.Mex. 45.
Hybernia indocilis, biology and control, 380.
Hybrid vigor in corn, 30.
Hybridization—*see also* Animal breeding *and specific animals and plants.*
interspecific, in *Gossypium* and meiotic behavior of F_1 plants, 189.
predicting hybrid ratios, N.Y.State 608.
Hybrids, reciprocal, quantitative characters in, 762.
Hydrangeas—
chlorosis control in, Ohio 340.
greenhouse, color, control, 350.
Hydrocyanic acid gas—
concentration in air mixtures, electrical method for determining, Fla. 658.
fumigation, paralysis due to time of recovery from, 226.
Hydrogen-ion—
determination, microscale for, 754.
determination of minute quantities of fluid, microquinhydrone electrode for, 151.
meter, direct-reading for glass, quinhydrone, and hydrogen electrodes, 151.
Hydrology of region west of 100th meridian, 702.
Hydrophobia, *see* Rabies.
Hylastes cunicularius, studies, 657.
Hylemyia—
antiqua, *see* Onion maggot.
brassicae, *see* Cabbage maggot.
cilicrura, *see* Seed-corn maggot.
Hylurgopinus rufipe.
associated with spread of Dutch elm disease, 231, 371.
trap-log studies, 524.
Hymenolepis carioca in poultry, Mich. 260.
Hyostrongylus rubidus, early developmental stages, U.S.D.A. 107.
Hypera postica, *see* Alfalfa weevil.
Hypericum seed, retarded germination caused by tap water, 625.
Hyphantria cunea, *see* Webworm, fall.
Hypochlorites, germicidal potency, evaluation, 687.
Hyponomeuta padella larvae, effect of arsenicals, 807.
Hypophyseal, anterior, hormone in urine following ovariotomy during pregnancy, 765.
Hypophysis—*see also* Pituitary.
anterior—
from rats before and after puberty, sex comparison of gonadotropic content, 327.
lobe and development of gonads, 469.
nervous control, 409.

Hypophysis of castrated male rats implanted into hypophysectomized females, effect, 327.
Hysteroneura setariae, *see* Plum aphid, rusty.
Inrovization, *see* Vernalization *and specific crops.*
Ice cream—
body, texture, and quality, Ind. 831.
qualities, relation to age and temperature, Mo. 98.
quality and overrun, effect of source of fat and serum solids, Mich. 683.
using frozen cherries in, 690.
vanilla, composition, effect on crystalline structure, Mo. 98.
Ice wells in farm refrigeration, N.Dak. 535, 549.
Ichneumonidae, biology, 79.
Ichthyology, problems in, 375.
Icterohematuria, studies, Colo. 252.
Idaho Station publications available for free distribution, 575.
Idaho Station, report, Idaho 735.
Idiocerus spp. on mango inflorescence in Philippines, 375.
Illinoia pisi, *see* Pea aphid.

collecting in the field, apparatus for, U.S.D.A. 76.
collecting, revolving screen trap for, U.S.D.A. 76.
collecting, trap for, U.S.D.A. 76.
control by radio waves, 224.
economic, in Australia, 808.
economic, in Sierra Leone, 808.
garden, biology and control, 807.
garden, control, 374; U.S.D.A. 655.

Insects—Continued.
handling, combination brush and needle for, U.S.D.A. 77.
identification, Mont. 658.
in airplanes, 809.
industrial fumigation against, U.S.D.A 80.
injurious, in Colorado, Colo. 224.
injurious, in Uganda, 808.
injurious to crops, *see special crops.*
leaf-feeding, thiuram sulfides as repellents, 512.
life history chart, frame for, U S.D.A. 75.
living, collecting tube for, U S D.A. 75.
marking with aluminum paint to determine molts, U.S.D.A. 75.
minute, cage for rearing, U.S.D.A. 76.
nitrophenols as stomach poisons for, 513.
of Canada, 374.
of Province of Quebec, Part IV, Odonata, 806.
of Puerto Rico, annotated check list, revision, P.R.Col. 806.
of Queensland, 375.
of shade trees, developments, 663.
orchard, *see* Orchard insects *and* Fruits, insects affecting.
periodical recurrence as scourges, Mo. 77.
photography, camera stand for, U.S.D.A. 76.
range, control, lizards as aid, 511.
rearing box for, U.S.D.A. 76.
rearing, inexpensive metal flats and cages for, U.S.D.A. 76.
rearing, laboratory method, U.S.D.A. 76.
relation to disease, 376.
relation to plant diseases, 637.
relation to transmission of virus diseases of potatoes, Me. 357.
scale, *see* Scale insects.
separating from host material, covered sifter for, U.S.D.A. 76.
stain for internal organs, U.S.D.A. 76
studies, treadle sifter for soil in, U.S.D.A. 75.
subterranean, soil sifters for, U.S.D.A. 76.
supercooling death, 809.
supplying liquids to, laboratory device for, U.S.D.A. 76.
treating with contact dusts, apparatus for, U.S.D.A. 76.
Insulation board, cornstalk, production and marketing, 262.
Insulin, effect on alteration of live weight in hens and pullets, 325.
Intestinal—
putrefaction, effect of cranberries, apples, and blueberries, Mass. 436.
stasis in low mineral diets, 422.
Intestines, large, of swine, epithelial diverticula in, 544.
Iodine—
deficiency, effect on thyroid gland of rat, 429.
in foods, 567.
Iodine—Continued.
in Hawaiian sea food and eggs, Hawaii 415.
in Oklahoma vegetables, Okla. 131.
in plants, S.C. 15.
in soils, determination, 301.
number of flaxseed oil, N.Dak. 475
Ionic exchange involving polyvalent cations, Mo. 15.
Iowa College, notes, 142, 576.
Iowa Station, notes, 142, 576.
Iowa Station, report, 141.
Ips engraver beetles, U.S.D.A. 511.
Iridomyrmex humilis, see Ants, Argentine.
Iris—
bulbous, foliage, diseases of, identification and control, 652.
bulbous, outdoor culture in Massachusetts, Mass. 493.
bulbous, speeding up flowering in, U.S.D.A. 350.
Cephalobus elongatus on, U.S.D.A. 207.
rot, Cupro-jabonite as possible control agent, Tex. 57.
Spanish, production, N.Mex. 45.
varieties, Iowa 44; Tex. 45.
variety tests, Mont. 626.
Iron—
availability in common foods, Wis. 564.
availability in ration for laying hens, Wis. 530.
availability in soils, relation to copper, 454.
available in plant and animal tissues, modifications of bipyridine method, 743.
effect on growth and fruiting, S.C. 37.
egg yolk and bran as sources in human diet, 883.
for hemoglobin formation, banana as source, 725.
in biological materials, determination, 157.
in blood of chicken, factors affecting, 828.
in corn plants grown in culture solutions at pH values of 3.0 to 8.0, N.J. 601.
in leather, determination, 157.
metabolism, study with preschool children, 725.
requirement of human adults, 883.
salts, internal administration for chlorosis of fruit trees, 220.
solubility, studies, 472.
storage by rats, sexual differentiation in, 883.
supply of plants in water culture experiments, 317.
use in curing goat's milk anemia, Wis. 535.
value in normal calf rations, Ohio 395.
with and without copper, effect on milk anemia, 427.
Ironing cotton fabrics, effect of variations in pressure and length of time of exposure, U.S.D.A. 573.

Irrigation—
and drainage in Western States, 702.
flood waters for, storage and use, Mont. 701.
methods, Mont. 701.
of subsoil, Ohio 340.
porous canvas hose, Mich. 701.
problems, practical, on which farmers need assistance, 702.
project, Sun River, status of agriculture on, Mont. 860.
projects, use of power on, 702.
pump, at North Platte Experimental Substation, Nebr. 852.
pumping, Nebr. 260.
pumping plants for farms, N.Mex. 551.
pumping problems in Great Plains area. 702.
resources of Montana, inventory and analysis, Mont. 550.
studies, Colo. 260.
water wheels and pumps for, Mont. 701.
Itonida pinifoliae, notes, 381.
Ixodoidea of Argentina, 85.
Japanese beetle—
attractiveness of various grades of geraniol, U.S.D.A. 84.
control, Conn.[New Haven] 374, 657; N.J. 817.
effect of desiccation on survival and metamorphosis, 816.
grubs, effect of low frequency alternating current, N.J. 658.
in soil, arsenates and arsenic trioxide for, relative effectiveness, 523.
lime and aluminum sulfate as repellent for, 523.
studies, Ind. 806.
traps and bait, improvements in, 523.
Japanese weevil in Connecticut, 232.
Jerusalem-artichokes—
culture and varieties, U.S.D.A. 620, 621.
sprouting of tubers, effect of planting date, 771.
Johne's disease—
in sheep, 695.
menace to cattle industry, 101.
Johnson grass, control, N.Mex. 37.
Jujubes, variety tests, Ga.Coastal Plain, 197.
Julus hortensis, injury to vegetables, Conn. [New Haven] 658.
June beetles on oaks, search for effective insecticide, Wis. 513.
Juniper webworm, control, 668.
Kale, tree, as green feed for poultry, Hawaii 388.
Kansas College, notes, 287.
Kansas Station, notes, 287.
Kelp, dehydrated, vitamin D in and hemoglobin building properties for chicks, 391.
Kentucky State Planning Board, report, 269.
Kentucky Station, notes, 142.
Keratin—
digestion by clothes moth larvae, 815.
relation to amino acids in human skin, Conn.[New Haven] 293.
wool, acid degradation, 584.
Kerosene—
use as contact insecticide, Minn. 668.
vapor, notes, Mass. 512.
Kidney, beef, nutritive value after heating and after alcohol extraction, 877.
Kidneys—
nutritional properties, Mo. 131.
of rats fed a diet poor in inorganic constituents, changes in, 881.
Knotweed, swamp, notes, 482.
Kolla n.sp., notes, 379.
Kudzu, fertilizer experiments, S.C. 37.
Labor—*see also* Agricultural labor.
income of owners and tenants, Mo. 119.
Lac host trees, insect pests, 808.
Laccifer lacca, bionomics, 809.
Lactalbumin v. casein in vitro, enzymic digestion, 722.
Lactation—
effect of hormones and lysats on, 325.
effects of short-time gestations, Mo. 98.
energy increment, Mo. 87.
inhibition in rabbits with large amounts of oestrin, 615.
low cost diet for, 421.
physiology of, 614; Mo. 35.
studies, 421.
Lactic acid—
aerobic dissimilation by propionic acid bacteria, 606.
concentrations in blood and liver of rabbits, 6.
formation in liver, 6.
Lactobacillus—
acidophilus and decay of teeth, 733.
lycopersici, dissimilation of pyruvic acid by, 582.
plantarum, studies, 606.
Lactoflavin—
and vitamin B_2, distribution, 283.
fluorometric estimation, 743.
Lactose—
formation study, intra-mammary duct injections in, 832.
in mammary glands of rabbits, Mo. 98.
in milk, decrease, following production of artificial hypoglucemia, 685.
in milk, factors that may change, 527.
in milk from cows injected with sugars, 832.
in milk, variations in, 246.
injections into cows, effect on blood sugar and lactose in milk, 832.
nutritive value for man, 567.
utilization, necessity for fat in, Wis. 535.
Ladybeetle—
convergent, as enemy of melon aphid, Tenn. 81.
convergent, control of rosy apple aphid with, Conn.[New Haven] 657.
predators for pea aphid, Idaho 658.
Ladybird beetle, adaptability to control of mealybugs in greenhouse, Mass. 512.
Laissez faire in theory and practice, 268.
Lake vegetation as source of forage, Minn. 678.

Lamb—
dysentery, studies, 253, 538.
faceless hereditary basis for, Minn, 609.
quality and palatability, effect of feeds, Mont. 823.
roasting, searing v. constant temperature methods, Mo. 131.
vitamin B_1 and vitamin G in, S.Dak. 728.
Lambs—
calcium, phosphorus, and vitamin D requirements, Ohio 389.
comparison of rations, Wash. 88.
early spring, on pasture, value of supplemental feeds, Tenn. 820.
early spring, production, breed performance in, S.C. 87.
effect of drench on gains and parasites, 400, 529.
ewe, effects of breeding, N.Dak. 91.
ewe, limited and full feeding, Mont. 676.
ewe, wintering, Mont. 677.
export, raising on subterranean clover pasture, 822.
fattening—
light v. heavy silage feeding for, Idaho 676.
methods of self-feeding and amounts of roughage, Mich. 676.
on beet pulp and molasses pulp, 679; Wyo. 822.
rations, Tex. 88.
rations, negative effects of phosphorus, Idaho 676.
self or hand-feeding for, 679.
feed lot losses among, N.Dak. 537.
feed utilization in, 528; Mass. 529.
feeding en route to market, frequency, Wash. 88.
feeding experiments, Ind. 819.
feeding in cornfields, Wyo. 89.
growth rate, relation to birth weight, Mass. 529.
losses caused by *Clostridium welchii* and *Eimeria faurei*, Colo. 252.
market classes and grades, U.S.D.A. 389.
marketing data of Canada, 276.
outlook charts, U.S.D.A. 120.
parasites, control, 400.
pastures for, Mo. 86.
pasturing on beet tops, Wyo. 89.
range, weaning weight, effect of age, 679.
shearing, Ind. 819.
spring, production, effect of cross-breeding, Calif. 92.
stiff, Wyo. 103.
summering on the forest, Mont. 676.
thin native, fattening, Md. 93.
western, fattening, Okla. 94.
Lamps, neon, mercury vapor, and Mazda, comparison for greenhouses, Ohio 44.
Land—
agricultural—
and grazing, assessed acreage in certain counties, N.Mex. 120.
Land—Continued.
agricultural—continued.
classification, Mont. 616.
use in Ohio, Ohio 411.
burned areas, measurement of debris transported from, 702.
classification, Ohio 353.
classification and soil survey, N.Dak. 444.
classification, bases, 445.
classification of Missouri, Mo. 15.
classification, system, 445.
credit, *see* Agricultural credit.
economic survey of Hubbard County, Minn. 121.
economics, rural, Calif. 709.
flooded, reclamation, 852.
forest, *see* Forest.
in Nebraska, most profitable use, 331.
of Missouri, acreages in different uses, Mo. 119.
ownership and tenure, Mont. 270, 861.
planning, principles, 269.
policies, western, and recent ownership trends, 555.
program, national, economic implications, 554.
public, and ranch stability in Nevada, Nev. 271.
reform, Czechoslovakian, results, 554.
regional surveys, methods employed by geographers in, 860.
relief, effect on agricultural value and utilization of soils, U.S.D.A. 749.
resettlement in England, history, 272.
rural, use in Kentucky, 270.
submarginal farm, in New York State, 271.
submarginal, objectives and types of development on, 268.
use and agriculture in Oregon, graphic summary, Oreg. 121.
use in Broome County, New York, [N.Y.]Cornell 860.
use in Chemung County, economic study, [N.Y.]Cornell 270.
use in Tennessee, inventory, 861.
use in Tioga County, New York, [N.Y.] Cornell 861.
use planning, 268; Iowa 852.
use planning, responsibility of animal husbandry in, 527.
use planning, utilization of soil surveys for, Conn.[New Haven] 306.
use program, adjustments—
in beef production from, 527.
in dairy production from, 527.
in pork production from, 527.
in sheep production from, 528.
use program for Cotton Belt. 473.
use program, three trends in, 331.
use programs, bases for, 269.
use, regional, symposium, 476.
Lard—
Cuban imports, Iowa 119.
effect of soybeans and soybean oil meal, Iowa 86.
hydrogenated, as culinary fat, Ind. 877.

Lard—Continued.
use in making cake, Nebr. 277; N.Dak. 564.
Lards, relative shortening values, Iowa 130.
Larvae, inflating, new apparatus and technic, U.S.D.A. 511.
Laryngotracheitis—
infectious, egg-propagated virus of, 546.
infectious, studies, 102, 259; Mass. 537.
infectious, vaccination, Mich. 691; N.J. 691.
of fowls, infectivity experiments, 402.
Laspeyresia nigricana, see Pea moth.
Lataniа scale on avocado, life history and control, 380.
Latrodectus mactans—
experimental studies, 387.
morphology, biology, etc., Ark. 387.
notes, Conn.[New Haven] 657.
rare in Michigan, Mich. 819.
Lausanne Viticultural Station, fiftieth anniversary, memorial treatise, 783.
Lawn pests and weeds, control, R.I. 767.
Lawns—
lime for, N.J. 53.
management, Mich. 476.
planting and maintenance, Colo. 52.
Lead—
arsenate—
deposit, effect of electrostatic charge, 224.
foliage burn by, spray tests for, Conn.[New Haven] 374.
soaps as spreaders, Wash, 79.
substitutes for, Conn.[New Haven] 374, 657; Mo. 77.
in canned foods, determination, 301.
in drinking water, compared with hazard from spray residue, 340.
in urine, minute amounts, determination, new method, 441.
on apples, accuracy of determination, 441.
residue removal—
effect of spray programs, 340.
from apples, wetting agents for, 345.
from fruit, Wash. 45.
results in, 808.
Leaf-footed bugs, notes, Fla. 658.
Leaf—
rollers, life history cages for, U.S.D.A. 76.
structure, modification by X-rays, 184.
tier of sweet rocket, Conn.[New Haven] 657.
Leafhoppers—*see also special hosts.*
food plant notes, 379.
large numbers, apparatus used in identifying, U.S.D.A. 77.
on mango inflorescence in Philippines, 375.
vectors of encephalitis, 668.
Leather, iron in, determination, 157.
Leaves—
absorption of radiation by, 181.
cooling and transpiration, 603.
Leaves—Continued.
freshly unfolded, water vapor loss from, 183.
of fruit species, absorption by water by, 486.
temperature and cooling by radiation, 455, 758.
transparent specimens, preparation, 321.
Lebistes reticulatus, effect of X-rays on sex gland and secondary sexual characters, 469.
Lecithin synthesis in hens, Fla. 717.
Legume—
cover crops, winter, effects on cotton, S.C. 37.
hay with and without high protein concentrates for dairy cows, Ind. 834.
inoculants, inspection, N.J. 339.
seedlings, effect of pythiaceous damping-off fungi, Iowa 55.
seeds, analyses and digestible nutrients, U.S.D.A. 821.
seeds, nitrogen fixation by, 187.
Legumes—*see also* Green manure *and* Alfalfa, Clover, *etc.*
adaptability for pastures, [Conn.]Storrs 194.
adaptation studies, Hawaii 330.
and corn, interplanting, S.C. 37.
and nonlegumes, inoculation, value of commercial cultures, Iowa 15.
as silage, preservation, S.C. 98.
damping-off, control by seed treatment, 494.
fertilizer experiments, N.H. 474.
for green manure, tests, Iowa 35.
for hay and pasture, tests, Iowa 35.
for renovating grub-injured pastures, possibilities, Wis. 475.
forage, composition, relation to growth and maturity, Fla. 615.
forage, insects affecting, biology and control, 807.
forage, variety tests, Alaska Col. 766.
hard-coated seeds, mechanical and acid treatment, Iowa 111.
in rotation, effect on corn yields, Ind. 767.
inoculation—*see also* Nodule bacteria.
studies, Tex. 38.
manure, and commercial fertilizers, 36.
nitrogen fixation in, relation to carbon assimilation, 760.
on neglected hay lands, N.H. 474.
production in Panhandle, [Okla.]Panhandle 195.
residual effects, [N.Y.]Cornell 450.
small-seeded, nurse crops for, Iowa 35.
species and varieties for pastures, [Conn.]Storrs 332.
v. nonlegumes, nitrogen fixation with, Mass. 444.
variety tests, Fla. 615; Idaho 616; S.C. 37; Tex. 38.
variety tests for soil improvement, Miss 331.

Legumes—Continued.
viability of hard seed remaining in soil, 625.
wild, root nodule bacteria, 320.
winter, with oats and rye for hay and pasture, S.C. 37.
Leguminosae, chromosome numbers in, 607.
Leis dimidiata var. *15-spilota*, introduction and propagation, Fla. 658.
Lemon—
cuttings in solution cultures, phosphorus relations, 631.
fruits, healing of wounds in, effect of potash fertilization, 368.
mal secco, search for strains resistant to, in British India, 368.
Perrine, bark disease, Fla. 802.
Lemons—
composition, nutritive value, and use, Hawaii 879.
Italian, known as Interdonato, probable origin, 191.
propagation, etiolation shoot method, 50.
Lemosa fruit, vitamin A in, 571.
Lentil seeds, germination, effect of sulfur waters, 317.
Leopard moth, studies, N.J. 658.
Lepidoderma albohirtum on sugarcane, 808.
Lepidoptera from State of Minas Geraes, list, 816.
Lepidopterology, Moroccan, 374.
Lepidosaphes—
beckii, *see* Purple scale.
morgani in southern California, 639.
Leptinotarsa decemlineata, *see* Potato beetle, Colorado.
Leptoglossus phyllopus, *see* Leaf-footed bug.
Leptomastix longipennis, identity, 385.
Lespedeza—
annual, cutting test, Tenn. 767.
cultural and utilization studies, Wis. 475.
culture experiments, Ga.Coastal Plain 194.
hay and alfalfa hay for dairy cows, comparison, N.C. 99.
in mixtures on grub-eaten hillside pastures, tests, Wis. 475.
Korean, in rotations, Mo. 42.
Korean, introduction into Missouri, Mo. 36.
reestablishing in sod, S.C. 37.
species in Louisiana, 473.
tests, Ind. 767.
variety tests, Fla. 615; Ga.Coastal Plain 194; S.C. 37; Tenn. 767; Tex. 38.
Lespedeza—
capitata, notes, Iowa 44.
sericea—
culture experiments, Tenn. 767.
cutting and grazing tests, S.C. 37.
experimental results, 472.
seed treatment tests, Tenn. 767.
stem blight, 788.
tests, Tex. 38.
Lettuce—
breeding, Hawaii 339.
culture, Me. 340.
drop, control, N.J. 638.
fertility, photoperiodism, and genetics, 30.
genetical studies, 190.
Iceberg, outer green and inner bleached leaves, vitamins in, 136.
industry of New York, effect of quality, [N.Y.]Cornell 865.
iodine in, Okla. 131.
seeds, storage, 46.
variety tests, Fla. 626; Ohio 340.
Leucocytes in blood, effect of hydrochloric acid injection, 255.
Leucoptera coffeella, notes, 808.
Leucosis—
fowl, and sarcomatosis produced by same virus, 547.
of fowls, Mo. 102.
Leukemia—
etiology, Fla. 547, 690
transmission studies, 259.
Leukopenia in monkeys due to vitamin-deficient diet, 426.
Levulinic acid, oxidation by hydrogen dioxide in presence of cupric salt, 5.
Libraries, public, in South Dakota, S.Dak. 875.
Library facilities in Missouri, survey, Mo. 560.
Lice—
infesting domestic animals, P.R. 840.
problem of municipal workhouses, Minn. 664.
Life, length of, relation to growth rate, 134.
Light—*see also* Sunlight.
and water, effect on stem elongation and expansion of leaves, 185.
artificial, intensity and wavelength, relation to photoperiodic responses of greenhouse annuals, 756.
artificial, use for flowering plants in greenhouse, Ohio 43.
colored, effect on reproductive growth of long-day and short-day plants, [N.Y.]-Cornell 26.
effect on carotenoid formation in tomatoes, [N.Y.]Cornell 629.
effect on *Lobelia* seed germination, 456.
effect on plant growth, 409.
effect on plants, physiology, 181.
effect on transpiration, 312.
intensity, effect on manganese in plants, 755.
neon type, applicable to general laboratory use, U.S.D.A. 76.
role in plant life, 456, 755.
trap, novel, 511.
visible, inactivation of lactoflavin and vitamin B_6 by, 284.
Lights v. no lights for egg production, Fla 675, 676.

Lignin—
in plants, analysis, 742.
role in nitrogen preservation in soils and composts, 600.
Lilies, Easter, imported, development of floral axis and new bud, 52.
Lilium henryi embryo sac, macrosporogenesis and development, 184.
Lily diseases, control, 652.
Lima beans, see Beans, lima.
Lime—*see also* Calcium *and* Liming.
agricultural, analysis, N.J. 24.
and aluminum sulfate as repellent spray for Japanese beetle, 523.
and soil improvement studies, N.J. 592.
application to lawns, N.J. 53.
growth response of crops to, S.C. 16.
movement in soils as determined by soil reaction, Mich. 752.
need and use in West Virginia, W.Va. 178.
potash absorption studies, Tenn. 747.
products, inspection, Mass. 178.
requirements of soils, *see* Soils.
status and requirement of soils, determination, 599.
Lime tree—
bark disease, Fla. 637.
looper, notes, Conn.[New Haven] 657.
Tahiti, bark disease, 788; Fla. 802.
Limes (fruit)—
Bearss, rootstocks for, 631.
composition, nutritive value, and use, Hawaii 879.
Persian, rootstocks for, Fla. 626.
propagation, etiolation shoot method, 50.
Limestone
amount and depth of application, effect, [Conn.]Storrs 194.
calcium and magnesium, bacteriological and chemical effects on acid soils, Iowa 453.
fine, use, Mo. 15.
for bacterial wilt control, 404.
purity, new method for determining, 8.
Lime-sulfur—
review of recent investigations, 499.
substitutes in summer sprays for orchards, Mass. 512.
Liming—
of soils, laboratory study, Tenn. 747.
response of soils to, Mo. 15.
Limonius, account of genus, Me. 817.
Linden, starch and fat reserves in, seasonal changes, 24.
Linkage—
creeper and single-comb, in fowls, 611.
experiment, three-factor, in mice, 468.
in rabbits, 467.
of genes for nonyellow and pink eye in mice, 610.
Linospora gleditsiae n.sp., description, 654.
Linseed—
cake, feeding value, Colo. 531.
meal, effect in fattening rations, N.Dak. 529.
meal, feeding value, Kans. 531.
Linseed—Continued.
meal, hydraulic and expeller, for pigs, Ohio 388.
meal, protein in, variations, N.Dak. 475.
meal v. cottonseed meal, palatability, Mich. 821.
meal v. safflower oil meal, feeding value, N.Dak. 529.
Liothrips urichi, notes, 811.
Lipids of rat tissue fed diets—
low in cholesterol, effect of underfeeding and of vitamin A deficiency, 885.
with added cholesterol, effect of underfeeding and of vitamin A deficiency, 885.
Liponyssus silviarum, life history, habits, and control, 403.
Litchi, composition, nutritive value, and use, Hawaii 879.
Littleville, a parasitic community during depression, 715.
Live oak disease at Austin, Tex. 57.
Liver—
attempt at isolation of growth factor, Wis. 564.
beef, nutritive value after heating and after alcohol extraction, 877.
cells, binuclear, production, 326.
extract, essential dietary factor in, distinct from vitamins B_1, B_2, and B_4, and flavines, 889.
lactic acid formation in, 6.
nutritional properties, Mo. 131.
of rabbits, concentration of lactic acid in, 6.
proteins, effect of heat and hot alcohol, 148.
vitamin D in, 426.
vitamin G in, separation of flavines from, Wis. 564.
Livers, hard yellow, in sheep and cattle, Tex. 103.
Livestock—*see also* Animals, Mammals, Cattle, Sheep, *etc.*
auctions in Ohio, Ohio 709.
diseases, *see* Animal diseases *and specific diseases.*
financing in United States, U.S.D.A. 126.
for small farms, management, U.S.D.A. 86.
inventory, U.S.D.A. 128.
market trends, 529.
Marketing Association, Illinois, organization and operation, 712.
on farms October 1934 and supplies of livestock feeds, Iowa 119.
outlook charts, U.S.D.A. 120.
output in provinces of Canada, 276.
place in Alabama agriculture, Ala.Tuskegee 389.
poisoning—*see also* Plants, poisonous, *and specific plants.*
by timber vetch, losses from, Colo. 252.
relation to fungus development on cornstalks and grain, Ind. 840.

Livestock—Continued.
production-consumption balance, Mich. 559.
range, economic changes in production, Mont. 271.
rations, need of adding minerals to, U.S.D.A. 820.
under AAA, 413.
Living, standards of, *see* Standards.
Lizards as aid in range insect control, 511.
Lobelia—
inflata seeds, germination, 455.
seed germination in, 456.
Locoweed poisoning, Tex. 103.
Locoweed, studies, Wyo. 103.
Locust (tree)—
black, germination, relation to permeability of seed coat, Iowa, 44.
black, seed germination, 625.
black, seedlings, growth, effect of seed inoculation, 206.
black, starch and fat reserves in, seasonal changes, 24.
honey, leaf spot disease, cause, 653.
shipmast, an undescribed variety, U.S.D.A. 53.
Locusta migratoria—
Algerian race, phase variation and rate of development, 377.
breeding grounds and migratory areas in China, 377.
manilensis, notes, 377.
migratorioides—
colored illustrations, 377.
growth changes and structure of egg, 377.
rate of growth, coloration, and abnormal six-instar life cycle, 377.
suspected middle Niger outbreak area of, 377.
outbreaks in China, 810.
solitary and migratory phases, comparison of rate of metabolic activity in, 81.
Locustana pardalina, colored illustrations, 377.
Locusts—
African migratory, growth changes and structure of egg, 377.
brown, colored illustrations, 377.
desert, notes, 377.
migratory, Algerian race, phase variation and rate of development, 377.
migratory, distribution and ecological study of breeding ground in China, 377.
oriental migratory, biology, 377.

Mites—
affecting peach in Colorado, control, Colo. 513.
control in Washington, 375.
handling, combination brush and needle for, U.S.D.A. 77.
harvest, seasonal occurrence on voles and mice, 388.
notes, 807.
of genus *Dermanyssus*, synopsis, 388.
parasitic, host list, P.R. 840.
tarsonemid, conducting life history studies, U.S.D.A. 77.
Mitogenetic ray phenomenon, phases, 458.
Mohair—
and wool, Texas, grades and shrinkages, Tex. 88.
fineness, relation to age of animal, Tex. 88.
production, effect of pregnancy and early lactation, 528.
Moisture equilibrium in soil, establishment, 594.
Molasses—
beet pulp and oats with alfalfa hay for wintering ewes, Mont. 240.
beet pulp fed to milking cows, effect on milk flavor, 835.
cane, and pineapple bran, feeding value, Hawaii, 395.
cane, and pineapple bran, maximum amounts in dairy ration, Hawaii 396, 534.
dehydrated, value in dairy ration, N.J. 684.
for preserving alfalfa silage, Wis. 535.
hay silage, 684.
mineral content, Miss. 879.
mixtures and pineapple bran for fattening swine, Hawaii 529.
Mold—
growth, effect of temperature, salt, and acidity, Minn. 689.
in butter, studies, 688.
proteins, growth of rats on, 566.
Moles as pests in bulb plantings, U.S.D.A. 72.
Molybdate and tungstate ions, action in water and sand culture experiments, 318.
Molybdenum—
role in growth and development of *Aspergillus niger*, 462.
specific catalytic role in nitrogen fixation and amide utilization by *Azotobacter*, 600.
Moniezia expansa in sheep, 696.
Monilia spp., isolation from black knots, 68.
Monilinia, North American species, 605.
Monkey infected with oesophagostoma intestinalis, anatomical view, 103.
Monkeys, spontaneous virus diseases in, 540.
Monocalcium phosphate v. bone meal for cattle, Mont. 530.
Monochaetia mali, relation to apple canker, 220.
Montana College, notes, 576.
Montana Station, notes, 576.

Montana Station, report, 735.
Moorlands, cultivation, soil science in, 169.
Mosaic disease, *see specific host plants.*
Mosquito larvae, toxicity of some optically active and inactive rotenone derivatives, 671.
Mosquitoes—
control, Conn.[New Haven] 374, 657; N.J. 658.
Culex, autogenous and anautogenous races, biology, 381.
transmission of equine encephalomyelitis by, 848.
vectors of encephalitis, 603.
Moth catcher for use in segregating individuals, U.S.D.A. 76.
Moths, trapping, use of lights in, Ind. 806
Motion pictures of United States Department of Agriculture, U.S.D.A. 277.
Motor truck tires, overloading, 265.
Motor trucks—
economical loading and operation, 265
relation to fruit and vegetable marketing, 554.
sedan delivery, convenient pockets for, U.S.D.A. 76.
Mountain-laurel, response to lime, Tenn. 779
Mouse—*see also* Mice *and* Rodents.
white-footed, nematode from, description, 804.
Mowers and binders, care and repair, U.S.D.A. 117.
Muck soils—
acid and alkaline, improvement, Ohio 306.
fertilizer experiments with onions. [N.Y.]Cornell 628.
fixation of potash by, 177.
management and crop production studies, Utah 310.
of Everglades, role of copper, manganese, and zinc in, Fla. 591.
pasture studies on, Fla. 616.
solubility of applied nutrients and composition and quality of crops from, Mich. 171.
treatment with sulfur and salt, Mich. 592.
Mulberry canker due to *Fusarium* sp., control, N.J. 638.
Mules, supply, 528.
Murgantia histrionica, see Harlequin bug.
Musca domestica, see Housefllies.
Muscle, bound water and phase equilibria in, 234.
Muscular exercise—
economy of, 569.
prolonged, effect on metabolism, 568.
Mushroom flies, nicotine fumigation for, N.J. 658.
Mushrooms, nutritive value, 718.
Muskmelon—
diseases and insect pests, spraying for control, N.J. 638.
Fusarium wilt, relation to soil temperature, 495.
leaf and fruit spot, Tex. 57.
Muskmelons—
as substitute crop for cabbage, Iowa 44.
of Iowa, quality and marketing, Iowa 44.
plant protectors and other factors affecting earliness, Ark. 199.
quality, factors affecting, Ind. 778.
Mustard—
greens, iodine in, Okla. 131.
tender leaves and tops, vitamin B_1 in, 571.
Mutation—
in *Trichothecium roseum,* 466.
involving coat character in mice, 610.
lethal, in Dark Cornish fowl, 468.
lethal, in rabbits, 762.
recent dominant, in Norway rat, 324.
seedcd, of Panariti grapes, 31.
Mutations—
hairless, in Norway rat, 610.
in corn, induced by irradiation and spontaneous, comparison, Mo. 36.
loss, in corn, Iowa 334.
Mycobacterium tuberculosis—
avium, notes, 110.
staining, new method, 105.
Mycosphaerella—
fragariae, mode of action of bordeaux on, 788.
rubina, ascopore discharge studies, N.J. 638.
Myiases of wounds and fruits, 816.
Myrothecium roridum, notes, 788; Tex. 57.
Mystrosporium on bulbous iris, control, 652.
Myxomatosis cuniculi virus, use in rabbit plague control, 539.
Myzocallis ulmifolii, notes, Conn.[New Haven] 657.
Myzus cerasi, see Cherry aphid, black.
Myzus persicae, see Peach aphid, green.
Nairobi disease, studies, 102.
Naphthalene—
as greenhouse fumigant, Mass. 225, 512.
poisoning in poultry, 849.
toxic effects on bean weevil and yellow mealworm, 660.
β-Naphthol bands for codling moth control, 376.
Napier grass—
cutting experiments, Hawaii 330.
effect of zinc sulfate, Fla. 210.
ensilability, Fla. 683.
fed whole v. cut as roughage, Hawaii 534.
fertilizer experiments, Fla. 615.
fertilizer, pasture, and silage tests, S.C. 37.
green, v. green Sudan grass as roughage, Hawaii 534.
Napomyza chrysanthemi, see Chrysanthemum leaf miner.
Narcissus—
bulbs, production, N.Mex. 45.
bulbs, speeding up flowering in, U.S.D.A. 350.
Fusarium bulb rot, 370.
paper white, forcing, 350.

Nasturtium, doubleness in flowers, inheritance, 31.
National Resources Board, recommendations, 702.
Naval stores yields, variations in, effect of weather and specific days between chippings, U.S.D.A. 635.
Nebraska Station, notes, 287.
Nebraska Station, report, 286.
Necrology, notes, 896.
Nectarine-peach cross, cytology, N.Y.State 191.
Nectria—
canker of trees, 223.
diseases in hardwoods of New England, 802.
galligena canker of pear, U.S.D.A. 207.
galligena, notes, 503.
sp., isolation from black knots, 68.
Negroes, educational facilities in rural communities, 130.
Nematode—
diseases of plants, U.S.D.A. 207.
meadow, notes, U.S.D.A. 207.
parasites of wheat wireworm, Me. 817.
Nematodes—*see also* Root knot nematodes.
calcium cyanamide for control, 654.
chemical control, Tenn. 789.
control, Tex. 78.
from Trinidad deer, 655.
in swine, early developmental stages U.S.D.A. 107.
leaf, plants attacked by, U.S.D.A. 635.
new hosts for, 208.
on begonias, control by pyrethrum preparation Hydra-Tox-Ultra, 370.
soil, in forest nurseries, 509.
Nephritis, chronic, in cattle and sheep, Tex. 103.
Nervous system, central action of *Trichomonas foetus* on, 540.
Neurolymphomatosis—
differentiation from lymph leucosis, Mass. 537.
pathological cell in, differentiation from lymphocytes of fowl blood, Mass. 537.
pearly eye in, Mass. 537.
New Hampshire Station, report, 575.
New Hampshire University, notes, 142.
New Jersey, planning surveys and planning studies, 270.
New Jersey Stations, report, 735.
New Mexico College, notes, 894.
New Mexico Station, notes, 287, 894.
New Mexico Station, report, 141.
New York Cornell Station, notes, 736.
New York State Station, notes, 576, 736.
Nezara viridula, *see* Stinkbug, southern green.
Nicotine-bentonite, toxicity on apples, persistence, 661.
Nicotine—
fixed, early work with, 512.
sprays, history, 656.
sulfate and white oil mixture for control of a fruitfly, 816.
Nitidulids, dispersion, methods and apparatus for study, U.S.D.A. 76.
Nitrate of soda, *see* Sodium nitrate.
Nitrates—
assimilation in soils, Iowa 15.
excessive soil, control, Colo. 168.
in meat and meat products, determination, 302.
seasonal production by different nitrogen carriers, Conn.[New Haven] 330.
Nitrification—
in soils, Nebr. 169.
process and plant nutrition, 174.
studies, Tex. 16.
Nitrogen—
accumulation or depletion in soils under different treatment, Mo. 15.
amide, and ammonia, determination in plant tissue, 158.
amino forms in sugarcane, effect of potassium, 437.
carriers, effect on potato yields, S.C. 37.
carriers for cotton, S.C. 37.
compounds with hydrogen and with oxygen, 581.
cycle of developing apple fruit, 314.
deficiency in plants, testing with diphenylamine, Mass. 497.
determination, combination of catalysts to reduce digestion time in, 157.
determination in plant tissues, micro-Kjeldahl method for, 742.
fixation—
by *Azotobacter*, specific intermediates in, 600.
by blue-green algae, conditions favoring, 599.
by *Rhizobium* spp. in pure culture, 456.
carbohydrate-nitrogen relation in, Wis. 21.
in soybeans, 471.
in soybeans, effect of exchangeable calcium, 599.
mechanism, relation to ammonia production by *Azotobacter*, 600.
with legumes v. nonlegumes, Mass. 444.
in cotton at various stages, 472.
in soils, effect of crops and cropping systems, 476.
in soils, effect of management, 311.
in soils from new areas in State, Idaho 592.
metabolic, of feces, relation to body weight and food intake, 424.
nitro and azo, semi-micro-Kjeldahl determination, 442.
nutrition of sugarcane, effect, 623.
preservation in soils and composts, function of cellulose and lignin in, 600.
responses from various sources, 472.
trichloride as fumigant, 655.
trichloride as fungicide for citrus fruits, Calif. 369.

Nitrogen—Continued.
utilization of round and liver and heart of beef, 565.
Nitrogenous—
fertilization, changes in status of soil after, Conn.[New Haven] 306.
fertilizers, availability, N.J. 592.
materials, utilization, Tenn. 747.
Nitrophenols as stomach poisons for insects, 513.
Nodule bacteria—*see also* Legumes, inoculation.
of legumes, studies, 463.
of wild leguminous plants, 320.
Nomadacris septemfasciata, life history, 377.
Nomenclature, botanical, discussions and actions at International Botanical Congress, 179.
Nonagria oblonga, notes, Conn.[New Haven] 657.
Nonlegumes v. legumes, nitrogen fixation with, Mass. 444.
North Dakota Station, report, 575.
Nucleus, bacterial, problem, 761.
Nummularia clypeus on soft maple, 789.
Nun moth—
hibernation, causes, 656.
temperature dependence, 656.
Nursery—
diseases, control, Iowa 55.
inspection, Conn.[New Haven] 657.
stock, distribution, Ohio 352.
Nutgrass eradication, sulfur bricks for, Tex. 57.
Nutrients, energy producing, utilization, effect of individual nutrient deficiencies, 722.
Nutrition—
and food, Hawaii 415.
and public health, 132.
human absorption by food plants of chemical elements important in, Mass. 444.
physiological bases, report, 133.
plant, *see* Plant nutrition.
relation to public health and to economic conditions, 133.
report of expert committee on, 134.
studies with rats, Conn.[New Haven] 424.
trace elements in, 724.
Nutritional—
response, regularity, relation to food, 135.
survey of Great Britain, 419.
Nuts, vitamin D in, 426.
Nuttalia, effect of splenectomy, 543.
Nysius ericae, *see* Chinch bug, false.
Oak—
flooring, commercial standard CS56-36, 855.
forests, effects of drought, Pa. 352.
leaves, composition, growth and seasonal changes in, 24, 206.
poisoning in range cattle and sheep, 842.
Oaks—
chlorosis control in, Ohio 340.
Diatrype stigma affecting, 789.
starch and fat reserves in, seasonal changes, 24.
Oat—
and pea silage, *see* Silage.
crown rust, effect on yield and chemical composition, 640.
crown rust, physiologic specialization and parasitism, Iowa 55.
hay, digestion experiments, N.H. 535.
hulls, hemicellulose from, 294.
root and stem disease, studies, 59.
seed, State certified, N.J. 339.
seeds, effect of organic mercury dusts, Iowa 55.
smut—*see also* Smuts *and* Cereal smuts.
fungi, inheritance of chlamydospore characteristics in, 499.
fungi, origin and production of strains by mutations and hybridization, 210.
laboratory detection, 625.
resistance or immunity, breeding for, Mo. 36.
smuts—
control, 499.
loose and covered, reaction of varieties to physiologic races, 211.
physiology, 60.
Oats—
added to basal ration, effect on growth rate and slipped tendon in chicks, 828.
and dried molasses beet pulp with alfalfa hay for wintering ewes, Mont. 240.
and vetch, cost of production, Alaska Col. 766.
as substitute for bran and middlings in broiler rations, Ind. 819.
breeding, Ga.Coastal Plain 194; Idaho 616; Iowa 35; Mich. 616; Mont. 616; S.Dak. 617; Tenn. 767; Tex. 38; Wash. 38.
breeding, yields and winter hardiness data, U.S.D.A. 621.
coleoptiles, polarized growth and cell studies, 318.
Columbia, breeding, Mo. 36.
combine investigations, Minn. 618.
composition, effect of crown rust, 640.
covered smut resistance, inheritance, 607.
culture, Mo. 42.
culture experiments, Ga.Coastal Plain 194; S.C. 37; Wyo. 39.
effect of zinc sulfate, Fla. 210.
fertilizer experiments, Fla. 615; Ga. Coastal Plain 194; La. 474; Tex. 38.
for chickens, 681.
frosted, problem, 626.
Fulghum, introduction into Missouri, Mo. 36.
Fulghum, occurrence and origin of fatuoids in, 189.

Oats—Continued.
hulled, effect on skeletal and muscular development in pigs, Ohio 388.
inheritance studies, Wash. 38.
Iowa No. 444, desirable for Upper Peninsula, Mich. 195.
outlook charts, U.S.D.A. 120.
pasture, value for fattening hogs, Tex. 88.
prepared v. whole, effect on colts, Iowa 824.
response to phosphorus, Mont. 616.
response to soil reaction, R.I. 767.
rotation experiments, U.S.D.A. 617.
seed-borne diseases, dust fungicides for, tests, Iowa 55.
seedlings, etiolated, effect of light, 318.
sowing on bluegrass and Bermuda sod, Tenn. 767.
sprouted, feeding value for pigs, Hawaii 388.
sprouted, vitamin C in, 571.
susceptibility to *Rhizoctonia solani*, 61.
treatment, effect on saccharogenic and dextrinogenic amylases during germination, 792.
value in rations for pullets, S.Dak. 677.
varieties, acre yields, Ind. 767.
varieties, introduction, testing, and distribution, Mont. 616.
variety tests, Alaska Col. 766; Fla. 615; Ga.Coastal Plain 194; Idaho 616; Iowa 35; La. 474; Mo. 36; N.Dak. 474; N.J. 616; N.Mex. 36; Nebr. 195; S.C. 37; Tex. 38; Utah 334; Wash. 3; Wyo. 39.
variety-cultural experiments, Iowa 35.
wild, germination, N.Dak. 475.
winter, leaf reddening in western Oregon, U.S.D.A. 207.
with weed seeds lodged on palea, unsuitable for seed, 777.
Octopus, Hawaiian, flesh and liver, vitamin A in, Hawaii 415.
Odonata, ordinal name for dragonfly, derivation and meaning of, Minn. 663.
Oesophagostomiasis in sheep, chemotherapy, 538.
Oesophagostomum—
apiostomum, studies, 103.
dentatum, early developmental stages, U.S.D.A. 107.
spp., notes, 400.
Oestodes sp., notes, Me. 817.
Oestrin—
action on mammary secretion, 470.
administration, effect on mammary development of normal and hydrophysectomized male guinea pigs, 328.
administration of large doses, effect on lactation, 615.
continued injection into young rats, effect, 615.
effect on ovaries and adrenals, 614.
extraction from urine, effect of different acids, 614.
Oestrin—Continued.
inhibition by progestin-containing extracts of corpus luteum, 470.
injections, reaction of anterior pituitaries of castrated female rats to, 471.
Oestrogenic—
dihydroxy compounds in urine of pregnant mares, 471.
hormone and mechanism of corpus luteum formation in rabbits, 327.
hormone, effect on development of mammary gland, Mo. 35.
substance, administration to male rabbits, development of female characteristics in, 327.
substance of male urine and bull testis, nature, 34.
substance, theelin, and theelol from male urine and bull testis, comparison, 34.
Oestrone injection in Brown Leghorn capons, variation in plumage response, 765.
Oestrous cycle—
in vitamin A-deficient animals, demonstration, 570.
of cows, effect of phosphorus deficiency, Minn. 684.
relation to endocrine glands, 614.
Oestrum
and menstrual cycle, comparative experimental endocrinology, 326
and ovulation in ewes, 528.
in sows, regulation by endocrine preparations, 325.
inducing in ovariectomized rats, 329.
Oestrus ovis, *see* Botfly, sheep.
Ohio Station, report, 431.
Oil-
dispersion into tank mixtures, injection method, 224.
emulsions and soap washes as summer sprays for peach, 514.
emulsions, home-made, results for orchard spraying, 514.
fuel, effects on plants, 188.
gage, precision, description, 585.
meal, *see* Linseed meal.
seeds, analyses and digestible nutrients, U.S.D.A. 821.
sprays, effect on apple trees, Wash. 46.
sprays, effects on shade trees, 514.
sprays, experiments, Conn.[New Haven] 374.
sprays for dormant applications, Mass. 512.
sprays, tank-mixture method of using, value, 514.
Oils—*see also* Fats *and specific oils*.
and excise taxes of 1934, U.S.D.A. 712.
less refined mineral, on leaf surfaces after spraying, 659.
petroleum, effect on plant respiration, 603.
tropical, sterol content, Hawaii 415.
Oklahoma College, notes, 895.
Oklahoma Station, notes, 895.

Okra—
iodine in, Okla. 131.
spineless, breeding, S.C. 45.
wilt, seeds as carriers, 788.
Olcsicampe sp., parasite of western hemlock sawfly, 819.
Olives, maturity, oil content as criterion, 302.
Onchocerca genus, validity of various species, catalog, and hosts, 841.
Onchocerciasis, Central American form of disease, 841.
Onion—
aphids, biology and control, Iowa 77.
leaf blight, notes, Tex. 57.
maggot eggs, ovicidal tests on, Ohio 374.
pink root, etiology, Tex. 57.
pink root, notes, Tex. 58.
pink root, varietal tolerance, Iowa 55.
seeds, storage, 46.
sets, production, Mass. 483.
thrips, biology and control, Iowa 77.
thrips, control, Mass. 512.
thrips, notes, Fla. 658; Ohio 374.
thrips, studies, 377; N.Mex. 78; S C 78; Tex. 78.
thrips, varietal resistance to, Idaho 658.
thrips, varietal susceptibility, 515.
Onions—
breeding, Mass. 483.
cost of production, Ind. 863; Mich 866; N.J. 711.
cull, utilization, Mass. 563.
culture and fertilization, Tex. 45.
fertilizer experiments, N.Mex. 45, 200
fertilizer experiments on muck soils, [N.Y.]Cornell 628.
irrigation studies, N.Mex. 45.
kerosene and petroleum oils in, distribution, 62.
magnesium requirements, Va.Truck 779
pungency, relation to variety and ecological factors, 342.
Sweet Spanish, breeding, Colo. 197.
Yellow Bermuda, fertilizer experiments. Tex. 341.
Oniscus asellus, injury to rhododendron seedlings, Conn.[New Haven] 657.
Oospora—
citriaurantii, effect of gases on, Calif. 369.
lactis, growth, effects of salt concentration, temperature, and acidity, Minn. 689.
lactis, relation to keeping quality of butter, Minn. 688.
scabies, see Potato scab.
types found in butter, 688.
Ootetrastichus spp., parasites of sugarcane leafhopper, Hawaii.Sugar Planters' 664.
Ophiobolus graminis—
nitrogen metabolism, 494.
on roots, crowns, and culms of wheat, 494.
Opihi, vitamin A in, Hawaii 415.
Opossum, susceptibility to virus of endemic typhus fever, 373.
Orange—
juice, California canned, manufacture and use, Calif. 711.
rust infections of *Rubus,* role of intracellular mycelium in, 221.
tortrix and *Platynota stultana,* relative abundance in southern California, effect, 230.
tortrix, control with cryolite, 230.
trees, Washington Navel, girdling test, 632.
Oranges—
California, physiological changes in rind during growth and storage, 632.
California, regulating shipments, Calif. 125.
cold storage studies, Fla. 626.
Hawaiian, composition, nutritive value, and use, Hawaii 879.
propagation, etiolation shoot method, 50.
refrigeration in transit from California, U.S.D.A. 51.
Trovita, new variety, description, Calif. 50.
Valencia, inherent unstable strain of, 348.
Washington Navel, Robertson strain, 51.
yield and quality, effect of copper sulfate, 627.
Orchard—
cover crops, 629; Wash. 45.
diseases in Delaware, 856.
insects, control by measures other than spraying, 224.
inspection, *see* Nursery inspection.
sanitation for disease control, 647.
sanitation through burning of floor cover, Ind. 806.
sites, selection in southern Michigan, Mich. 486.
Orchards—*see* also Fruits, Apples, Peaches, *etc.*
damage from apple fruit moth, 374.
fertilization, Wash. 45.
heating, 13.
irrigated, soil moisture relations, Wash. 46.
irrigation, Wash. 46.
soil improvement with hairy vetch, Mo. 44.
soil management, Ind. 778.
soil moisture studies, Nebr. 197.
spraying with home-made oil emulsions, results, 514.
Orchestes pallicornis, see Apple flea weevil.
Organic—
compounds, chlorine determination in, 589.
compounds, molecular structure and interfacial energy, Minn. 581.
matter—
accumulation in soil, factors affecting, 310.

Organic—Continued.
matter—continued.
decomposition, Colo. 168.
in Nebraska soils, restoration, Nebr. 168.
in plant material, destruction, 153.
in soil, determination, Walkley and Black method, practicability, 300.
in soils, decomposition, Iowa 15.
in Washington soils, maintenance, Wash. 15.
Oriental fruit moth, *see* Fruit moth, oriental
Oriental moth parasite, life history and habits, 526.
Orius insidiosus, important natural enemy of corn earworm, U.S.D.A. 81.
Ornamental plants, shrubs, and trees, *see* Plants, Shrubs, *and* Trees.
Ornithodoros—
megnini, see Ear tick.
papillipes, vector of relapsing fever in Palestine, 255.
parkeri n.sp. on rodents, 819.
talaje in Argentina, 85.
talaje in Arizona, host relations, 819.
Ornithology, development in Philippines, 375.
Orthoptera—
of North Dakota, N.Dak. 515.
rearing cage, U.S.D.A. 76.
studies, Iowa 77.
Oryctes rhinoceros, control by trap crops infected with green muscardine fungus, 208.
Osier, insects affecting, biology and control, 807.
Osteomyelitis wounds healing with blowfly maggots, 105.
Ostertagia circumcincta, experimental infections of lambs with, 697.
Ova in vivo and in vitro, comparative behavior, 193.
Ovarian—
extracts, residual, effect of injection, 34.
follicular hormone, crystalline, chemical nature, 470.
grafts and folliculin benzoate, action on comb and spurs of capons, comparison, 330.
hormone, pigmentary response in plumage, hereditary transmission, 468.
Ovariectomy—
changes in size and histology of uteri of rats following, 35.
during pregnancy, hormones in urine following, 765.
Ovaries—
of bovine, percent of fetuses in left and right cornu of uterus, 326.
of hypophysectomized rats treated with urinary hebin, histology, 765.
of immature rats, development, effect of gonad-stimulating hormones, 613.
of pig, prepuberal development, relation to stimulation with gonadotropic hormones, 327.
Ovens—
constant-temperature, inexpensive, U.S.D.A. 655.
used for domestic cooking, studies, Ind. 892.
Ovicides, studies, N.H. 512.
Oviduct—
of hen, secretory activity of different sections, 824.
perforation in domestic fowl, 469.
Ovulation—
and oestrum in ewes, 528.
in sows, regulation by endocrine preparations, 325.
time of and rate of sperm travel in sheep, 469.
Ox, 3-day fever of, 102.
Oxidations, biological, studies, 741.
Oxygen, evolution in process of photosynthesis, 181.
Oxyuris sp. from Trinidad deer, 655.
Oysters—
biology, N.J. 658.
story of, 277.
Oystershell, pulverized, feeding value, Tex.

Ozonium omnivorum root rot, distribution in shelterbelt zone of Texas, 495.
Packing houses, screening, Ind. 806.
Paint—
and paint materials, symposium on, 856.
coatings, durability, effect of extractive substances in wood, U.S.D.A. 114.
old coatings on fences, exposure test, 262.
Palm chestnut, culture, P.R. 778.
Palm, coconut, *see* Coconut.
Panscopus torpidus on strawberries, Oreg. 232.
Papaya fruitfly, effect of freeze of 1934, 663.
Papayas—
carotene content, Hawaii, 415.
composition, nutritive value, and use, Hawaii 879.
Paper
corrugated, apparatus for cutting, U.S.D.A. 76.
mulches and bagasse, effect, 19.
Paraffin—
failure to stimulate yeast growth relation to effect of heavy water, 456.
sections sliding together, prevention, 464.
Paralysis
breeding as factor in control, 529.
fowl, and lymphocytoma, comparison, 546.
fowl, breeding for high and low resistance to, Mass. 529.
fowl, etiology, Fla. 547, 690.
fowl, flock resistance to, Idaho 690.
fowl, relation to incubation environment, Ohio 397.
fowl, so-called Marek's, studies, 402.
fowl, studies, 259; [Conn.]Storrs 252; N.J. 691.

Paralysis—Continued.
infectious bulbar—
in cattle, Ohio 397.
in rhesus monkey, 105.
transmissible through external auditory canal, 840.
range, in poultry, etiology and mode of transmission, Iowa 102.
range, of fowls, 401.
Paranagrus spp., parasites of sugarcane leafhopper, Hawaii.Sugar Planters' 664.
Parasites—
and parasitic diseases of swine in Puerto Rico, P.R. 548.
associated with stem weevil of cotton in south India, 818.
breeding cage for, U.S.D.A. 76.
breeding, underground room for, 511.
insect, transportation, thermally insulated unit for, U.S.D.A. 511.
intestinal, of animals, 805.
of cattle under Everglades conditions, Fla. 690.
of domesticated animals and man in Hawaii, U.S.D.A. 103.
rearing by Forest Protection Experiment Station in Prague, 656.
rearing tray for special requirements, U.S.D.A. 511.
seed-borne, detection and identification, 625.
work for 1935, Conn.[New Haven] 657.
Parasitism and disease, lectures on, 252.
Parasitology, veterinary, in Philippines, 253.
Paratetranychus—
citri, *see* Citrus red mite.
pilosus, *see* Red mite, European.
Paratrioza cockerelli, control, Wyo. 811.
Paratuberculosis, *see* Johne's disease.
Paratyphoid—
in turkeys, 700.
in turkeys, transmission through eggs Idaho 690.
infection of pigeons, N.J. 691.
organisms, differentiation, 850.
Paresis in rats, due to chronic avitaminosis, 285.
Pareumenes quadrispinosus, biology and parasites, 85.
Paris green, homologs, 514.
Parthenogenesis, aposporic, in triploid apple, 323.
Partridges, gray and stone, coccidian affecting, 403.
Passion fruit—
composition, nutritive value, and use, Hawaii 879.
culture, Hawaii 339.
Pasteurella—
genus, antigenic studies, 841.
infection in guinea pig stock, 693.
inoculated eggs, hatchability, 260.
isolation from equine cerebral tissue, effect of culture media, 692.
Pasteurization, *see* Milk.
Pasture—
contour furrowing machine, description, 408.
crops on rice stubble, Tex. 38.
forage, harvesting samples, method, 99.
grasses, *see* Grasses.
herbage, artificially dried, comparative digestibility by sheep and rabbits, 678.
mixtures and fertilization, N.J. 616.
mixtures, tests for dairy cattle, S.Dak. 684.
plants, new, introductions for Southeast, 472.
plants, root development and deterioration, Fla. 615.
research, fundamentals, 473.
research literature in United States and Canada, digest, U.S.D.A. 195.
species, response to plant nutrients, [Conn.]Storrs 194.
Pastures—*see also* Grasses, Grassland, *and* Meadows.
bluegrass, improvement, Mo. 36.
comparison for dairy cattle, S.Dak. 684.
crops and seeds mixtures, tests, Tex. 38.
cumulative effect of weather conditions, Ohio 331.
differently fertilized, seasonal variations in, [Conn.]Storrs 39.
economical, for horses, 528.
experiments, Mich. 616.
experiments with beef cattle, Ga.Coastal Plain 238.
fertilizer experiments, 472; Mass. 474.
grazing systems and fertilizer tests, Mo. 36.
grazing value, effect of fertilizers, 472.
improvment, Iowa 35; Wis. 475.
improvement and management, Tex. 38.
improvement by fertilization, Me. 330.
improvement in the South, treatise, 619.
increasing productivity, Mo. 15.
irrigated, manured, Mont. 616.
irrigation, use of electricity for, 265.
Longleaf grazing test, 768.
management, Kans. 39; La. 39.
methods for producing, Ala.Tuskegee 389.
monthly clipping, results, 474.
native and improved, comparison, 473.
permanent, for east central Texas, Tex. 38.
permanent, management, Nebr. 195.
permanent, supplementing with summer annuals, 472.
potash requirements and use in Vermont, Vt. 619.
production, effects of fertilizer treatments, [Conn.]Storrs 194.
response to clipping, Ohio 331.
response to fertilizers and cultivation, Hawaii 330.
response to manure, lime, and fertilizers, Ind. 767.
response to phosphate, relation to time of liming, N.J. 617.

Pastures—Continued.
rotational grazing, Wis. 475.
soil conditions and plant growth, factors affecting, Iowa 14.
studies, [Conn.]Storrs 332, 618; Fla 616; Ga.Coastal Plain 194; La. 534; Tenn. 767; Wyo. 39.
studies, technic, [Conn.]Storrs 194.
temporary, seeding and carrying capacity, Nebr. 239.
temporary, studies, Ga.Coastal Plain 238.
types and composition in Delaware Co., [N.Y.]Cornell 40.
use in economic production of milk in Delaware, 268.
vegetation, relation to exchangeable bases, Mo. 15.
white clover in, factors causing fluctuations, Ohio 331.
Pea—
aphid control, U.S.D.A. 655.
aphid, control, derris experiments for, 379, 664; U.S.D.A. 77.
aphid, ladybeetle predators, for, Idaho 658.
aphids, isolating on parts of a plant, cage for, U.S.D.A. 76.
diseases in Colorado, U.S.D.A. 207.
diseases, virus, Wash. 58.
mildew, downy and powdery, Wash. 58
mosaic, Idaho 637.
mosaic, relation to other legume viruses, 496.
moth, studies, Wash. 79, 815.
root rot, control, N.J. 638.
root rots, Idaho 637.
root tips, effect of centrifugal force, 604.
root tips, excised fragments, growth, 605.
seed, dusted, sowing, use of graphite to prevent clogging of drills, N.Y.State 266.
seeds, counting, apparatus for, U.S.D.A. 75.
streak caused by alfalfa mosaic, 496.
vine silage as feed for dairy cattle, Mont. 536.
virus diseases, 494.
viruses, identification, 62.
weevil control, plow attachments for, Idaho 701.
weevil, control, suggestions for, U.S.D.A. 511.
weevil, favorable hibernation important to, Idaho 658.
Peach—
aphid, green, and *Aphis abbreviata*, comparison as vectors of potato diseases, Me. 357.
borer, control, Ohio 202.
borer, lesser, notes, Ohio 374.
buds, resistance to injury at low temperatures, 490.
canker, infection studies, 366.
canker, prevention in Ontario, 220.
Peach—Continued.
disease, fungus, control, 366.
disease, new, Ohio 357.
disease, phony, control, U.S.D.A. 55, 356.
diseases, control in Tennessee, Tenn. 220.
fruit buds, Elberta, hardiness, relation to fertilizer treatment, 347.
insects in Colorado, control, Colo. 513.
leaf curl, control with creosote oil, 787
mosaic in Colorado, 207; Colo. 221.
mosaic in Kentucky, U.S.D.A. 636.
mosaic, studies, Colo. 207; Tex. 57.
nectarine cross, cytology, N.Y.State 191.
plats, uniformity trials, 627.
roots, growth, anatomy, and metabolism, effect of temperature, N.J. 627.
seed, non-afterripened, germination test, 783.
seeds, viability studies, 489.
sprays, zinc sulfate in, studies, Ill. 801.
trees, arsenical burn on, Conn.[New Haven] 657.
trees, longevity in some sections of Georgia, 627.
twig borer in California, 227.
virus diseases, U.S.D.A. 496.
X disease, Conn.[New Haven] 356.
yellows and little peach studies, 367, 495.
yellows, rosette, and little peach, immunological studies, 800.
Peaches—
breeding, N.J. 49, 627.
canned, prices received by canners, Calif. 712.
copper fungicides for, tests, 788.
cost of production, N.J. 711.
effects of copper compounds on, 495.
Elberta, effect of fertilizers, 627.
fall fertilization, 627.
fertilizer experiments, S.C. 45.
fruit thinning, Ohio 340.
hardiness, improvement in, Iowa 44.
harvesting, packing, and storage, Wash. 45.
maturity at harvest, relation to flesh firmness, keeping quality, and edible texture, N.J. 783.
outlook charts, U.S.D.A. 120.
pollination, 49.
propagation, N.J. 627.
rootstocks for, N.J. 627.
spray schedules for, Ohio 201.
storage, relation to break-down, 347.
variety tests, Ga.Coastal Plain 197; La. 483; S.C. 45.
winter injury, N.J. 627.
winter injury in Kentucky, U.S.D.A. 356.
Peanut—
butter, making and using, U.S.D.A. 278.
hay, feeding value, Fla. 675.
oil meal, feeding value, Kans. 531.
wilt due to *Sclerotium rolfsii*, 207.

Peanuts—
botany of, 187.
breeding, 473; Fla. 615; Ga.Coastal Plain 194; Tex. 38.
breeding for disease resistance, 788.
culture experiments, Ga.Coastal Plain 194.
fertilizer experiments, Ga.Coastal Plain 194; Tex. 38.
for laying hens, supplementary value, 529.
outlook charts, U.S.D.A. 120.
rotating with crotalaria and with native cover crops, Fla. 616.
Spanish, feeding for pork production, Fla. 675.
variety tests, Ga.Coastal Plain 194; Hawaii 330; Tex. 38.
yields, effect of zinc sulfate, Fla. 210.
Pear—
bitter pit and related diseases, Wash. 58.
blossoms, abscission, cause, 495.
crown girdle, freezing injury and fungi in relation to, 495.
diseases in western New York, 365.
diseases, notes, 799.
fire blight resistance, selection for, Tenn. 789.
leaves, absorption of water by, 486.
rots, studies, Wash. 58.
seedlings, growing, new method, 781.
thrips on plums, control, 887.
trees on quince rootstocks, notes, N.Y.State 48.
trees, soil management systems, Ohio 340.
trees, wilting in heavy clay soil, relation to soil moisture, 170, 346.
Pears—
Bosc, distribution of sugars in, 346.
breeding, Iowa 44.
canned Bartlett, prices received by canners on Pacific coast, Calif. 869.
fungi causing decay in Washington, 494.
metabolic gases other than carbon dioxide in, Oreg. 203.
Old Home, as pollinizer for standard varieties, Mich. 782.
pollination experiments, 488, 489.
root system, 48.
spray residue removal from, Wash. 46.
spray schedules for, Ohio 201.
variety tests, Ga.Coastal Plain 197.
Peas—
Austrian winter, diseases, U.S.D.A. 789.
Austrian winter, rotation studies, Fla. 616.
breeding, Alaska Col. 778; Idaho 616; Tenn. 767; Wash. 38; Wis. 483.
calcium deficiency effects on, 25.
canned, determination of quality in, 47; N.Y.State 11.
cannery, making more profitable, N.Y. State 201.
Peas—Continued.
canning, culture in Washington, Wash. 780.
canning, fertilizer experiments, Wis. 445.
canning, increased yields by control of aphids, Wis. 513.
canning, virus diseases of, Wis. 497.
cost of production, Alaska Col. 760.
culture experiments, Idaho 616.
effect of phosphatic fertilizers, Mont. 453.
English, diseases rare in early plantings, U.S.D.A. 496.
fertilizer placement for, N.Y.State 200.
field, as summer-seeded green manure, Mich. 893.
magnesium requirements, Va.Truck 779.
market, soil and cultural requirements, [N.Y.]Cornell 46.
onion thrips affecting, Tex. 78.
response to alfalfa in rotation, Idaho 616.
seed treatment, Wyo. 58.
susceptibility to *Rhizoctonia solani*, 61.
variety tests, Alaska Col 778; Idaho 616; N.Y.State 198; Ohio 340; Wash. 38.
viroses of, 496
vitamin C in, N.Y.State 728.
Peat—
classification system, 446.
deposits, genesis and composition, [N. Y.]Cornell 749.
electrodialysis, complex ions in relation to, 451.
Everglades, effect of green manuring of crops on, 451.
Everglades, nitrogen availability to crops, 451.
soils, capillary conductivity measurements in, 749.
soils of Everglades, role of copper, manganese, and zinc in, Fla. 501.
soils, pasture studies on, Fla. 616.
value in potting soil mixture, 197.
Pecan—
clusters, effect of bagging on drop, 492.
diseases, notes, U.S.D.A. 55.
leaves, moisture relations, 348, 369.
nut casebearer, notes, Fla. 658; Tex. 78.
orchard, effect of thinning trees, 633.
orchards, Florida, cover crop program for, Fla. 634.
rosette disease, relation to zinc and other mineral constituents, 507.
Pecans—
American, Europe as market for, U.S.D.A. 871.
cover crops for, Fla. 626.
culture experiments, La. 483.
fertilizers for, Fla. 626.
filling and maturity, 491.
food storage and growth, relation to nitrogen absorption, Fla. 626.
fruit development, 627, 787.

Pecans—Continued.
growth and yield, effect of thinning stand and other orchard practices, 491.
growth, effect of nitrogen fertilizers, 633.
nut thinning, effect on size, degree of filling, and yields, 492.
pollen viability and periods of receptivity, 627.
rootstocks for, Tex. 45.
variety tests, Fla. 626; Ga.Coastal Plain 197; La. 483; N.Mex. 45.
yield, effect of fertilizers, 633.
zinc requirements, Fla. 626.
Pectin in plants, analysis, 742.
Pectinophora gossypiella, see Bollworm, pink.
Pediculoides ventricosus, see Straw itch mite.
Pediculus, *see* Lice.
Peganum harmala, toxicity tests, N.Mex. 691.
Pegomyia hyoscyami, see Spinach leaf miner.
Pelamia repanda, notes, Tex. 78.
Pellagra-like symptoms due to egg white, new curative factor, effect on types of animals, 889.
Pemphores affinis—
identity, 385.
in south India, 818.
Penicillium—
digitatum on *Citrus aurantium,* 357,
roqueforti used in Iowa Blue cheese, protein and fat metabolism, Iowa 97.
spp., effect of gases on, Calif. 369.
Pennisetum purpureum, seedling strains, Hawaii 330.
Pennsylvania College, notes, 287, 895.
Pennsylvania Station, notes, 287, 895.
Pentachlorethane for eradication of root rot, tests, Tex. 57.
Peonies, varieties, Iowa 44.
Peony, *Septoria* leaf spot, U.S.D.A. 207.
Pepper seeds, germination, 780.
Pepper seeds, storage, 46.
Peppermint, breeding, Mich. 616.
Peppers—
breeding, Conn.[New Haven] 339.
Diaporthe phascolorum on, 214.
home-canned, botulism due to, 428.
variety tests, N.J. 627.
Peptides, multivalent, studies, 5.
Peridermium strobi, see White pine blister rust.
Peridesmia, feeding habits and condition of ovarian follicles, correlation, 386.
Perkinsiella saccharicida, see Sugarcane leafhopper.
Peromyscus, flexed-tailed, cause, 324.
Peronospora—
schachtii, new in New South Wales, 360.
sp. on *Chenopodium* and spinach, cross inoculation and morphological studies, 494.
tabacina, notes, U.S.D.A. 636.
Perosis and inorganic phosphorus, correlation, 828.
Pestalozzia funerea on conifers, Tex. 57.
Petroleum—
ceresin added to embedding wax, 321.
furfural combinations, effectiveness against noxious weeds, 777.
oil, impregnated with chemical compounds as codling moth larvicide, 521.
oils, effect on plant respiration, 603.
oils in water, cresoap emulsions, structures and formation, 740.
Petunia, powdery mildew affecting, U.S.D.A. 356.
Pezoporus sp, parasite of western hemlock sawfly, 819.
Phaeogenes spp., parasite of western hemlock sawfly, 819.
Phaeolus, new combination, 354.
Pheasants, ring-necked, nesting habits in northwest Iowa, 73.
Phenacoccus gossypii, notes, 655
Phenolase activity, measurement, 151.
Phenothiazine for codling moth control, tests, 670; U.S.D.A. 655.
Phidippus insolens, color markings, Ark. 387.
Phlox, perennial, resistant to powdery mildew, 495.
Phlyctaenia rubigalis, see Greenhouse leaf tier.
Phoma—
destructiva, notes, Fla. 637.
medicaginis, notes, Idaho 637.
sp., isolation from black knots, 68.
species affecting sugarcane, Iowa 55.
Phomopsis—
bark disease of lime and lemon, 802.
canker and gall disease of gardenia, 652.
canker of gardenia in Nebraska, U.S.D.A. 356.
citri, notes, 788.
on dewberry, N.J. 638.
sp. as secondary invader of cankers induced by winter injury, N.J. 638.
Phorbia brassicae, control, 656.
Phormia regina, vector of encephalitis, 663.
Phosphatase values of plasma bones and teeth, effect of fluorine, 730.
Phosphate—
carriers, relative availability, R.I. 752.
concentrations in nutrient medium, effect on plants, 172.
deficiency in calcareous soils, ascertaining, N.Dak. 445.
requirements of alfalfa, N.Mex. 619.
requirements of lemon cuttings, 631.
rock, v. superphosphate in southern Idaho, Idaho 592.
Phosphates—
basicity of, R.I. 747.
comparison, Ind. 747.
effect on plants, Mont. 453.
mono-, di-, and tricalcium, preparation and properties, 436.
retention by clay, 598,
selenium in, 176.
Phosphoric—
acid, selenium in, 176.
anhydride, citrate-insoluble, determination, modified technic, 297.

Phosphoric—Continued.
anhydride, removal by washing, comparison of filtration by gravity and by suction in, 298.
Phosphorus—
analysis, digesting biological materials for, 156.
and sulfur in plants grown on same soil, comparison, 317.
assimilation by *Aspergillus niger* and *Cunninghamella* sp., 173.
availability in calcareous soils, factors affecting, 175.
available, estimating by extracting soils with potassium carbonate solution, 298.
available, in Hawaiian soils, biological effect, 23.
available, in Iowa soils, Iowa 15.
available, in soil, *Cunninghamella* test, 23, 452.
deficiency, effect on oestrous cycle of cows, Minn. 684.
deficiency, tests to determine, Mont. 453.
deficient soils, studies, Mont. 452.
determination in soils, Colo. 540.
diet, low, of young pigs, effect, 241.
for animals, Mont. 530.
in alfalfa, Mich. 592.
in blood serum, colorimetric determination, Colo. 540.
in cheese, error in data reported, 277.
in cotton at various stages, 472.
in grasses and herbage, Colo. 540.
in New Jersey soils and availability, N.J. 592.
inorganic, and perosis, correlation, 828.
inorganic, forms in soils, 7.
milk forms as source, relative economy, 717.
of blood, studies, 423.
relation to soybean growth, nodulation, and composition, Mo. 773.
requirements of agricultural soils, 177.
requirements of chickens, 390.
requirements of cows, Vt. 834.
requirements of growing pigs, 528.
requirements of lambs, Ohio 389.
requirements of preschool children, 882.
requirements of soils, 586.
requirements of sugarcane and various grasses on Everglades soils, Fla. 591
soil deficiency disease of corn, U.S.D.A. 789.
solubility, studies, 472.
source test, S.C. 37.
studies on alkaline soils, Nebr. 169.
supplement for sugar beet byproduct rations, value, Utah 90.
supplements in steer fattening, negative effect, Idaho 676.
transport in cotton plant, 459.
utilization of round, liver, and heart of beef, 565.
water-soluble, varying amounts on soil types, response of cultivated crops to, 452.
Photographing objects from above, stand used in, U.S D.A. 76.
Photometer, variable layer photoelectric comparison, description, 295.
Photomorphus genus, female sex of, Minn. 674.
Photoperiodism—*see also* Day length.
in perennial plants, 313.
in sesamum, 313.
Photosynthesis—
in *Grimmia montana*, 181.
in Tropics, effect of season, 180.
limits of, Vt. 457.
studies, 181.
Phototropism, summary, 182.
Phthia picta, rare in the State, Tex. 78.
Phthorimaea heliopa, notes, 808.
Phycomyces, growth factors, conditions of action, 462.
Phyllachora maohaericola, notes, 208.
Phyllocoptes oleivorus, *see* Citrus rust mite.
Phyllophaga—
fusca, injury to seedling apple and pear trees, Conn.[New Haven] 657.
hirticula, control in lawns, Ohio 374.
Phyllosticta apicalis on golden willow, 789
Phymatotrichum omnivorum—
growth on normal roots and on roots decayed by root rot, 496.
immunity of monocotyledonous plants to, 494.
in Nevada, U.S.D.A. 789.
insects possible distributing agents, 373, 643.
notes, 788.
on winter and spring weeds of Texas, 643.
persistent strands in Texas, 787.
reversible vegetative dissociation of strains, 787.
sclerotia longevity in moist laboratory soil, 643.
sclerotia, separating, apparatus and procedure, 214.
soil relations, Tex. 65.
studies, Tex. 56, 57.
Phymatotrichum root rot—
immunity of monocotyledonous plants to, toxic principles determining, 788.
sulfur bricks for, Tex. 57.
Physocephalus—
sexalatus, early developmental stages, U.S.D.A. 107.
sp., notes, 400.
Physoderma zeae-maydis, notes, Fla. 636.
Physosteganta pustulata, notes, Conn.[New Haven] 657.
Phytomonas—
angulata, *Physalis subglabrata* as natural host, 646.
fascians, n.sp., notes, Ohio 357.
flava begoniae n.sp., description, 223.
glycinea, notes, 364.
insidiosa, effect on alfalfa, Wyo. 501.
phaseoli, notes, 364.
rhizogenes, development, environmental factors in, 648.

Phytomonas—Continued.
sojae, notes, 364.
solanacearum, notes, 207; Fla. 636.
spp., notes, Fla. 637.
stewarti infected corn, histological changes in resistant and susceptible strains, 496.
stewarti, notes, 360, 494; Iowa 321, 360; Mich. 642.
syringae, relation to blossom abscission of pears and apples, 495.
tabaci, notes, 219.
tumefaciens—
gall production in tomato by, 495.
notes, 495.
pathogenicity and viscosity in cultures, correlation, 187, 494.
studies, electrical potentials found in, 495.
Phytopathologists of Brazil, first meeting, 357.
Phytophaga destructor, *see* Hessian fly.
Phytophthora—
cactorum, effect of chloropicrin as soil fumigant, 638.
cactorum, notes, Ind. 789.
cactorum, sexual reproduction in, control, 754.
cambivora causing root disease in conifers and hardwoods, U.S.D.A. 780.
cinnamomi, notes, N.J. 638.
citrophthora, effect of gases on, Calif. 369.
disease of strawberry, 801.
drechsleri, description on sugar beets, 217.
faberi, notes, 207.
genus, morphology and physiology, Mo. 56.
infestans—*see also* Potato blight, late, on tomato, Conn.[New Haven] 356.
species causing heart rot of pineapples, pathogenicity and variation in, 506.
Pichia alcoholophila and *Saccharomyces acoris-sacchari*, dissociation, 606.
Pigeonpea—
seed meal, sulfur in, Hawaii 415.
wilt, effect of temperature and maturity, 804.
Pigeonpeas—
breeding, Hawaii 330.
mixed globulins of, sulfur in, Hawaii 415.
Pigmentation—
cold, of albino iris, retina, and hair, 469.
in skin and milk of Guernsey dairy cattle, N.J. 684.
Pigments—
carotenoid, of wheat, determination of concentration of small samples, Minn. 583.
of dilute alcohol or acetone extract of whole wheat meal, Minn. 583.
of gasoline extract of wheat, nature, Minn. 583.
Pigs—*see also* Sows *and* Swine.
daily gains and feed requirements, Tex. 88.
effect of low phosphorus rations, 241.
embryonic eye development, effect of rations deficient in vitamin A, Tex. 88.
fall, fattening for spring market on runner peanuts and sweetpotatoes, Fla. 675.
fattened on garbage, hyperinsulinization, 325.
fattening, Tex. 88.
fattening, corn distillers' dried grains for, Ohio 388.
fattening, economical rations for, Wyo. 89.
fattening experiments, S.C. 87.
fattening on native feeds, Hawaii 529.
fattening rations, Nebr. 239; S.Dak. 677.
fattening, Sudan grass pasture for, [Okla.]Panhandle 241.
fattening, winter forages for, comparison, 528; S.C. 823.
feeding experiments, Hawaii 388; N.Dak. 530; Nebr. 239.
gains made on different feeds, Fla. 675.
grinding corn for, degrees of fineness, Pa. 824.
growing and fattening, allowance of skim milk for, Mich. 676.
growthiness in, comparison under various treatments, 528.
hemolytic streptococci in tonsils, 841.
inbred and outbred, feed consumption, effect of individuality, 528.
inbreeding, eight generation experiment, Minn. 609.
lameness and death due to vitamin A deficiency, N.C. 531.
local and terminal market price differentials, Ind. 819.
management on small farms, U.S.D.A. 86.
marketing data of Canada, 276.
newborn, death loss in, Ind. 840.
number on South Carolina farms 1910–34, S.C. 120.
nutrition, N.H. 529.
on pasture, corn and barley for, Mich. 676.
on restricted level of feeding, effect of protein in ration, 528.
one-day and three-day weights, relative accuracy, 528.
outlook charts, U.S.D.A. 120.
parasites in slaughterhouses in Canton, 400.
pastures for, S.Dak. 677.
production and marketing in South Carolina, S.C. 556.
selling by local livestock cooperatives, effectiveness, Iowa 126.
shipping, rail and truck costs, Wis. 555.
spring and fall litters, feeding and management, Ga.Coastal Plain 238.

Pigs—Continued.
susceptibility to rabbit pox virus, 398.
trade in United States, trends in, Iowa 871.
trembling in, 697.
vitamin A in nutrition, 528.
warm dressing yield, effect of feeding at market, Ind. 819.
weanling, rations for, Mo. 86.
weights, fluctuation, 528.
with grain rations balanced with cottonseed meal, calcium requirements, Tex. 88.
worming, chenopodium experiment, S.Dak. 691.
Pimpla behrensiella, parasite of oriental fruit moth, 815.
Pine—*see also* White pine.
beetle, mountain, important parasite of, biology, 386.
blister rust, *see* White pine blister rust.
cankers induced by winter injury, secondary invaders, N.J. 638.
damage from red squirrel, 786.
growth rate in Arkansas, 786.
Japanese red, starch and fat reserves in, seasonal changes, 24.
Jeffrey, parasitism of *Arceuthobium campylopodum*, 508.
loblolly, penetration of *Trichoderma lignorum* into sapwood, 508.
pitch, root development, 53.
ponderosa, cut-over stands, Scribner volume tables for, 786.
ponderosa, timber growing and logging practice in, U.S.D.A. 786.
root and stem rot, etiology and control, N.J. 638.
Scotch, different strains, Ohio 852.
seedlings, reaction to shade, 785
shoot moth, European, control, Conn. [New Haven] 374.
shoot moth, European, studies, 230, 380; U.S.D.A. 77.
shortleaf, amount and distribution of moisture in, 352.
slash, chemistry of, 4.
slash, culture experiments, Tex 45.
southern shortleaf, status in northwestern Ozark region, 206.
sphingid, development, effect of temperature and humidity, 656.
tip moth, Nantucket, control, U.S.D.A. 511.
tip moths of southern Ohio, 669.
tip moths, preventing distribution, U.S.D.A. 77.
tree honeycomb rot problem, 508.
wood staining due to *Sphaeropsis ellisii cromogena* n.v., 372.
Pineapple—
bran and cane molasses, feeding value, Hawaii 395.
bran and cane molasses, maximum amounts, Hawaii 396, 534.
bran and molasses mixtures for fattening swine, Hawaii 529.
Pineapple—Continued.
bran as feed for mules, Hawaii 529.
bran, feeding value, Hawaii 395.
bran v. beet pulp as supplements to grain rations for dairy cows, Hawaii 534.
diseases in British Guiana, 357.
heart rot, studies, 506.
juice, canned, vitamins in, 726.
trash, decomposition, chemical changes during, 601.
Pineapples—
composition, nutritive value, and use, Hawaii 879.
general discussion, 491.
Pingue, cause of heavy losses of range sheep, N.Mex. 846.
Pinipestis zimmermanni, notes, 669.
Pipes, prestressed reinforced concrete, stresses in, 264.
Piroplasma, effect of splenectomy, 543.
Piroplasmosis—
equine, clinical observations, hematology, and therapeutics, 109.
of dogs, brown dog tick as vector, P.R. 840.
Pistol casebearer, outbreak, 667.
Pituitaries, extracting hormones from, methods, Mo. 35.
Pituitary—*see also* Hypophysis.
anterior—
extracts, action, augmentation by blood, 328.
gland of immature female rat, reaction to pregnancy urine, 33.
hormones, augmentation of ovary-stimulating action, 328.
reaction to injections of oestrin, 471.
relation to corpus luteum of pregnancy, 33.
extracts and pregnancy urine, effect on male genital system, differences, 765
gland, effect on ovaries and oviducts of hens, 325.
grafts, persistence in testis of mice, 470.
growth hormone, physiological effects, 723.
hormones, effect on lactation in cows, 325.
like hormone, milk as possible excretory source, 33.
synergist, augmenting ovarian response to, 328.
Pityogenes hopkinsii as secondary invader of cankers induced by winter injury, N.J. 638.
Placenta extracts, effect on ovaries and oviducts of hens, 325.
Planetree, oriental, new disease of, 371.
Plant—
anatomy in agricultural research, 43.
bugs, injury to fruit, Conn. [New Haven] 657.
bugs, larger, Fla. 658.

Plant—Continued.
cells—*see also* Cells.
multiplication, atypical and pathological, 208, 209.
photic excitation and phototropism in, 181.
photosynthetic system, quantitative photochemical study, 181.
salt absorption by, mechanism, 316.
tannin in, physiology, 316.
chromosomes, *see* Chromosomes.
containers, Mass. 483.
cover, relation to erosion control, Iowa 111.
disease immunity, hereditary factors, 465.
diseases—*see also* Fungi *and different host plants.*
and pests, injuries due to, 207.
bacterial, 353.
control, Mont. 637.
in Ceylon, 208.
in Delaware, 356, 357.
in New South Wales, 58, 358.
in New Zealand, 58.
in Tennessee, relation to weather, U.S.D.A. 55.
in United States, U.S.D.A. 54.
new or unusual, in Mississippi in recent years, 788.
new or unsual in Missouri, Mo. 56
new to Texas, Tex. 57.
relation to insects, 637.
survey, Conn.[New Haven] 356; N.J. 638; S.C. 56; Wash. 58.
virus, ring symptom, Ky. 790.
ecology, studies published in unexpected places, 180.
explorers of Kansas, lives and works, 179.
growth—
and transpiration, effect of wind velocities, 182.
effect of follicular and other hormones, 185.
effect of light, 409.
effect of vitamin C, 25.
hormone and cell division, 185.
hormone theory, significance, 185.
hormones, 402.
hormones, chemical nature, 185.
relation to minerals in soil, S.C. 16.
response to calcium in calcium sulfate and dolomitic limestone, S.C. 37.
inspection, *see* Nursery inspection.
juices, expressing, cylinder and piston for, U.S.D.A. 76.
life, role of light in, 456.
material, ashing, standardized method, 455.
material, destruction of organic matter in, 153.
material, imported for testing, U.S.D.A. 607.
Plant—Continued.
material, transparent specimens, preparation, 321.
metabolism, absorption of supplementary elements required in, N.J. 601.
nutrients, availability, relation to soil reaction, chart for teaching, 473.
nutrients in United States, inventory and balance sheet, N.J. 752.
nutrients, mobilization in soil, 171.
nutrition, active chemical factors in, simultaneous estimation, 587.
nutrition and nitrification process, 174
nutrition, minor elements essential for, 761.
nutrition, relation to mildew resistance, 791.
pathogens, seed-borne, detection, laboratory technics for, Iowa 55.
pathology, aspects of, 353.
pigments, *see* Pigments.
protectors, types for transplanted muskmelons, Ark. 199.
quality, electrometric determination, 459.
stem elongation and expansion of leaves, effect of water and light, 185.
substance, assimilation of inert matter by, 318.
tissues—
ammonia and amide nitrogen determination in, 158.
cytological study, nuclear crushing method, 754.
iron determination in, modifications of bipyridine method, 743.
living, killed, and injured, determination, 753.
nitrogen determination in, micro-Kjeldahl method for, 742.
spermatophyte, cultures of, 456.
unfreezable and freezable water equilibrium in during subzero temperatures, 184.
troubles, diagnosis with diphenylamine, 639.
tumors and oestrus hormone, 62.
virus inoculations, carborundum as an abrasive in, 790.
virus problem, 208.
viruses affecting legumes, identification, 62.
viruses, factors affecting, Mo. 56.
viruses, production of primary lesions by, effect of environment, 354.
viruses, serological studies, 354.
viruses, treatise, 790.
Plantain diseases in British Guiana, 357.
Plants—*see also* Flora *and* Vegetation.
action of fluorine and silicon-fluorine preparations, 761.
action of heat, light, and radiations, 181.
adaptation to low temperature, physiology, Minn. 785.
antibodies in, 463.

Plants—Continued.
catalase activity, effect of certain chemicals, Minn. 603.
change in membrane materials, physiological investigations, 742.
composition, effect of climate and soil type, Wash. 15.
cyanophoric, as animal intoxicants, 255.
effect of fuel oil on, 188.
effect of subjecting to light and dark prior to treatment with growth substances, 456.
effect of sulfureous mineral waters, 317.
electrical phenomena in, cause, 456.
fasciation and etiology, Tex. 57.
flowering, incidence of and losses by curly top, Idaho 637.
flowering, value of cloth houses for, Ohio 340.
freezing resistance, effect of radioactivity, 314.
freezing resistance, factors affecting, 313.
germinating, flavine enzyme systems in, 25.
green, assimilatory mechanism, effect of intense light, 181.
greenhouse, artificial light and reduction of day length for, Ohio 43.
greenhouse, effect of light, Ohio 340.
greenhouse, photoperiod and light intensity requirements, Ind. 778.
grown on same soil, phosphorus and sulfur in, comparison, 317.
hair development, effect of nutrition factors on, 461.
immunity to viruses, acquisition, Wis. 497.
improvement activities, S.Dak. 629.
in southern Florida, epiphytotic of algal spot on, U.S.D.A. 789.
in water culture, iron supply of, 317.
incoming and outgoing, inspection and entomological and pathological interceptions, 208.
iodine content, S C. 15.
long-day and short-day, reproductive growth, effect of colored lights, [N.Y.]Cornell 26.
magnesium requirements, Mass. 444.
manganese in, effect of light intensity, 755.
Minnesota wild and cultivated, edible fruits from, Minn. 735.
monocotyledonous, immunity to root rot, 494.
nitrogen deficiency, testing with diphenylamine, Mass. 497.
nutrient deficiency symptoms in, 472, Ohio 340.
ornamental—
crown rot in New Jersey, U.S.D.A. 636.
diseases caused by soil-infesting fungi, Mass. 496.
Plants—Continued.
ornamental—continued.
hardiness tests, Fla. 626.
in New Jersey, new or unusual disease outbreaks, U.S.D.A. 55.
insects affecting, Ohio 374.
insects affecting, biology and control, 807.
introduced, winter injury, Fla. 626.
propagation, Ohio 340.
susceptibility to root knot, Fla. 223.
tests, Alaska Col. 778; Tenn. 779.
varieties, Tex. 45.
variety tests, Fla. 626.
winter forcing, R.I. 779.
perennial, photoperiodism and frost resistance, 313.
phosphate concentration of solution cultures, effect, 172.
photosynthesis, *see* Photosynthesis.
physiological responses, use for determining absorption and transport of synthetic growth substances, 456.
poisonous—*see also* Livestock poisoning *and specific plants.*
studies, Mont. 637; Tex. 103.
to livestock in Florida, Fla. 690.
to livestock in Western Australia, 255.
potash deficiency symptoms in, Ind. 789.
potassium absorption by, 598.
prairie, osmotic pressure and water content, 29.
propagation, N.Y.State 48.
propagation by seedage, cuttage, layerage, and separation, Mo. 197.
propagation for possible erosion control value, Iowa 53.
propagation from cuttings, use of auxins, 318.
radiation phenomena in, 458.
reactions to ultraviolet light, 27.
resistance to parasites, effect of boron, 356.
respiration, *see* Respiration.
response to day length and temperature, 755.
response to localized applications of chemical agents, 456, 461.
synthesis of carotene from carotenoids in, Wis. 564.
transpiration, *see* Transpiration.
tropical horticultural, notes, Hawaii 339.
useful to waterfowl, distribution and ecology, Iowa 24.
water relations, 459.
woody, *see* Woody plants.
Plasmodiophora brassicae, notes, 496.
Plastids, amylogenic capacity and organic mass, 319.
Platynota stultana—
and orange tortrix, relative abundance in southern California, effect, 230.
control with cryolite, 230.
life history on greenhouse roses, 519.

Pleospora rehmiana, notes, Idaho 637.
Plesiocoris rugicollis, notes, 807.
Pleuropneumonia—
bovine, causal agent, 695.
bovine, treatment, 543.
infectious, of goats, 102.
infectious, of goats, behavior of virus, 847.
Plinthodes taeniatus on strawberries, Oreg. 232.
Plodia interpunctella, *see* Indian meal moth
Plow attachments for pea weevil control, Idaho 701.
Plow, terracing, use for soil conservation, 706.
Plow trash shield, Purdue, description, Ind. 856.
Plowing, good, factors in, Ill. 408.
Plows—
mechanism of, 472.
moldboard operation and basic factors involved in shapes, 407.
national program, 471.
Plum—
aphid, rusty, transmission of sugarcane mosaic by, 811.
black knot, studies, 68.
brown rot resistance, R.I. 779.
curculio, bionomics and control, Iowa 77.
curculio in apples, Mass. 512.
curculio, partial second brood in Virginia, 672.
curculio, studies, S.C. 78.
sawfly, control, 387.
Plumage—
character of fowls, effect of folliculin benzoate administration, 329.
response in Brown Leghorn capons to oestrone injection, variation, 765.
Plums—
breeding, Iowa 44.
classification of varieties, flower characters for, 490.
culture in Missouri, Mo.Fruit 490.
Ember, characteristics, 48.
Methley, value, Tenn. 779.
root system, 48.
spray schedules for, Ohio 201.
varieties, Ind. 778.
variety tests, Ga.Coastal Plain 197; Ind. 778; Wyo. 46.
Plutella—
maculipennis, *see* Diamondback moth.
porrectella of sweet rocket, Conn.[New Haven] 657.
Pneumonia—*see also* Pleuropneumonia.
chronic progressive, of sheep, etiology and transmission, 695.
Pnyxia scabiei, injury to carrots, 512.
Poa compressa, seed germination, effect of soil in relation to nitrate solution, 455.
Podosesia fraxini, *see* Ash borer.
Poha, composition, nutritive value, and use, Hawaii 879.
Poinsettia—
chlorosis in Washington State, U.S.D.A. 55.
crown and root rot, Tex. 57.
Poinsettias, sand culture, N.J. 627.
Poisonous plants, *see* Livestock poisoning, Plants, poisonous, *and specific plants*.
Poisons, effect on insects, physiological studies, Idaho 658.
Poll evil in horses due to *Brucella abortus*, 258.
Pollen—
analysis, methods and significance, 635.
germination on stigma, method of studying, 344.
grains, evolution, 459.
grains of tomato, effect of carbohydrate and of nitrogen deficiency, 464.
Pollination, *see specific plants*.
Polychrosis viteana, *see* Grape berry moth.
Polydactyly in swine, 32.
Polyploidy and susceptibility to frost, 322.
Polyporaceae, European, agricultural relations, 354.
Polyporus hispidus on walnuts, 369.
Polyspora lini, notes, 494.
Pomace fly—*see also Drosophila*.
persistence of *Erwinia amylovora* in, 639.
response to hydrocyanic acid gas, comparison of criteria of susceptibility, 226.
Pomphopoea sayi, *see* Blister beetle, Say's.
Pondweed as forage crop, Wyo. 89.
Pontia rapae, *see* Cabbage worm, imported.
Popcorn—
breeding, Iowa 35.
variety tests, Iowa 35.
Popillia japonica, *see* Japanese beetle.
Poplar—
cambial activity in the polarity phenomena, 319.
insects affecting, biology and control, 807.
leaves, development of intumescences on, role of auxin, 456.
seeds, storage, germination, and respiration, 634.
starch and fat reserves in, seasonal changes, 24.
Poppy weevil in Hungary, life history, 385.
Population—
back-to-the-land movement in southern Indiana, Ind. 871.
mobility, 715.
of a selected cut-over area, La. 128.
of counties in Michigan, changes in, Mich. 872.
resources and prospects, Mont. 270.
rural, in Ohio, origin, Ohio 269.
Poria incrassata, rotting of floor timbers by, 789.
Pork—
curing and storing, Tex. 88.
curing, salt absorption in, rate and amount, 528.

Pork—Continued.
fat, effect of soybeans and soybean oil meal, Iowa 86.
muscle protein in experimental diets, response of rats to, Iowa 130.
production, adjustment to land planning program, 527.
quality, effect of feeding paradichlorobenzene treated corn, 528.
quality, effect of soybeans and products, Ind. 819.
roasting, searing v. constant temperature methods, Mo. 131.
trade in United States, trends in, Iowa 871.
Porthetria dispar, *see* Gypsy moth.
Posts of native woods, treatment, Conn.[New Haven] 405.
Potash—
availability, testing with *Aspergillus niger*, 300.
available in fertilizer residues extracted by Official method, 300.
available in mixed fertilizers, determination, 298; Ind. 747.
available in mixed fertilizers, loss in extraction by Official method, 299.
deficiency symptoms in growing plants, Ind. 789.
fixation by muck soils, 177.
for cotton wilt and rust control, 644.
for orchard trees, Ohio 340.
growth response of crops to, S.C. 16.
in apple trees, Thornton test for, 345.
in soils from new areas in State, Idaho 592.
outgo, effects of 12-year residues of lime and magnesia, 177.
requirements of soils, 586.
requirements of Vermont pasture soils, Vt. 619.
residual effects on cotton, S.C. 37.
source test, S.C. 37.
sources for citrus, Fla. 626.
water-soluble, loss in fertilizer mixtures, 155.
Potassium—
absorption by plants, 598.
bromate, standard solutions, preparation, 296.
carriers, effect on potato yields, S.C. 37.
chloride, rates of applying for side dressing on cotton, S.C. 37.
detection, zinc cobaltinitrite for, 155.
determination, 154.
dichromate, standardization, 7.
effect on sugarcane, 437.
fertilizers, time and rate of applying to cotton, S.C. 37.
fixation by soil, relation to estimating available nutrients, 598.
in soil, effect of fertilizers and cropping, Del. 750.
liberation in soils, effects of liming, Iowa 454.
replaceable, in Oklahoma soils and field response to potash fertilization, 471.
Potassium—Continued.
requirements of agricultural soils, 177.
transport in cotton plants, 459.
Potato—
Alternaria disease, 216.
bacterial wilt, control, 494.
bacterial wilt, notes, 66.
beetle, Colorado—
history in Belgium, 384.
variations in seasonal history, 384.
vegetable dusts in combating, 807.
beetles, effect of Alorco, Tenn. 84.
black scurf, control, Iowa 55.
blight, late, notes, 66.
brown rot, control, Fla. 636.
brown stem or *Rhizoctonia*, effect of soil moisture and seed disinfection, N.J. 638.
disease records from certification inspections in Nebraska, U.S.D.A. 207.
diseases—
control, Fla. 636; S.C. 56.
in Malaya, 65.
virus, decrease in susceptibility of some races, 216.
virus, seed transmission, 794.
virus, studies, Idaho 637; Me. 357; Mont. 637; N.Dak. 497; Wash. 58.
early blight, control, N.Mex. 56.
farms, costs for labor, fertilizers, and taxes, Me. 411.
farms in Aroostook County, cash expenses, monthly distribution, Me. 411.
flea beetle, control, Conn.[New Haven] 374; Me. 374; Nebr. 224.
flea beetle, feeding and utilization of sucrose solutions by, 659.
flea beetle on tobacco, control, U.S.D.A. 655.
leaf disease, notes, 66.
leaf, diurnal changes of carbohydrates, effect of potassium chloride, 316.
leaf roll, effect of place on, N.H. 497.
leafhopper—
control, Ind. 800; Wis. 513.
injury to alfalfa and red clover, 517; Ky. 518.
notes, Fla. 658.
on cotton, S.C. 78.
on dahlia, control, 511.
population, effect of variety, Ohio 374.
losses due to seed piece decay and blackleg, Me. 357.
mosaic, composite infections, reaction of seedling to, 495.
mosaic, effect of place on, N.H. 497.
mosaic, effect on growth, composition, and efficiency of plant, 216.
mosaic in Green Mountain seed plats, Me. 357.
mosaic, latent, acquired resistance to, 495.
plants from basal and apical sets, relative vigor and productivity, N.Y.State 195.

Potato—Continued.
plants in water and in sand cultures, physiological experiments, 215.
powdery scab in Australia, 364.
psyllid, control, Nebr. 224; Wyo. 811.
psyllid, spraying experiments, N.Mex. 77.
psyllid yellows, histology, biochemistry, and control, N.Mex. 56.
scab, *Actinomyces* isolation from, 644.
scab and soil actinomyces, Vt. 644.
scab, control, 787; Iowa 55; Wis. 497.
scab control, effect of aluminum sulfate and sulfur, N.H. 474.
scab, development, effect of fertilizers, N.J. 638.
scab, effect of soil application of sulfur, Tex. 57.
scab gnat, injury to carrots, 512.
scab, seasonal occurrence, 662.
scab, susceptible varieties, 216.
scab, types, relation to *Actinomyces* of, 216.
seedling tests, Fla. 637.
soft rot during harvesting and storage, 65.
species, frost resistance, 337.
tuber diseases, 207.
tuber diseases, effectiveness of treatment, Fla. 616.
tuber rot, 495.
tuber worm on tobacco, 808.
tubers, seasonal occurrence of injuries to, 662.
tubers, sprouting, effect of temporary anaerobiosis on, 310.
tubers, wounded, corking-over processes, factors in, 207.
vines, killing with sulfuric acid to hasten maturity, Me. 330.
viruses, European and American, comparison, 794.
viruses, list, 363.
wilt in middle Asia, toxins of, 363.
yellow dwarf, effect of high temperatures, Wis. 497.
yellow dwarf virus, insect and host relations, 494.
Potatoes—
abnormalities in certain varieties, Colo. 362.
bordeaux mixture v. copper sulfate with Wyo-Jel for, Mass. 497.
breeding, Iowa 35; Mich. 616; Wash. 38.
Cephalobus elongatus on, U.S.D.A. 207.
cooked, blackening in, associated with potash deficiency, Wis. 497.
cooking quality, Me. 330.
cooking quality, palatability, and carbohydrate in, effect of storage temperature, U.S.D.A. 565.
cost of production, Mich. 735.
cost of production in northern Indiana, Ind. 863.
culinary quality, 718; Colo. 278; Wyo. 131.
cull, feeding value, Colo. 531.
culture and storage research, 771.
Potatoes—Continued.
culture experiments, Fla. 616; Ga. Coastal Plain 194; Tenn. 767; Tex. 38.
culture in Florida, Fla. 478.
demand for in Twin Cities, Minn 559.
effects of vernalization, 185.
fertilizer experiments, 473; Alaska Col. 766; Conn.[New Haven] 330; [Conn.]Storrs 194; Fla. 615; Idaho 616; La. 337; Me. 330; N.Mex. 36; R.I. 767; Wash. 38.
fertilizer formulas, S.C. 37.
for fattening lambs, Wash. 88.
Green Mountain, tuber cracking in, Me. 330.
growth inhibition in, caused by gas emanating from apples, 463.
improvement program, contribution from plant pathologist, 364.
improvement program in North Carolina, 474.
in rotation, Alaska Col. 766.
iodine in, 567; Okla. 131.
irrigation and planting tests, Mich. 616.
Katahdin, tests in Michigan, Mich. 772.
kerosene and petroleum oils in, distribution, 62.
magnesium requirements, Va.Truck 779.
maturity and type, effect of fertilizers, 771.
Netted Gem, vitamin G in, Idaho 726.
new rotation for, Ohio 331.
new Warba, Ohio 331.
nonlegumes as green manures for, 771.
nutrition and soil fertility studies, 771.
on muck soil, Ohio 772.
outlook charts, U.S.D.A. 120.
periderm and cortex color inheritance in, 190.
phosphorus content, Mont. 453.
production in Michigan, economic study, Mich. 273.
production in Nebraska, papers on, 337.
production of alcohol from, Idaho 701.
research on, Ohio 621.
respiration, effect of handling, 29.
response to phosphorus, Mont. 616.
rotation experiments, N.H. 474; U.S.D.A. 617.
Sclerotinia rot of, 788.
seed, cut and uncut, corrosive sublimate treatments, Mo. 36.
seed of Irish Cobbler, production, Ohio 331.
seed pieces, effect of size on food reserves in, 474.
seed, relative vigor of apical and basal pieces, 478.
seed treatment for *Rhizoctonia* control, 644; Idaho 637; Wyo. 58.
seed-piece decay, Fla. 637.
spraying and dusting, Me. 330.
spraying experiments, Fla. 637; Mass. 512; N.J. 638; Ohio 357.
spraying with bordeaux, yield increases from, Conn.[New Haven] 356.

Potatoes—Continued.
storage, Nebr. 195.
Triumph, disease-free seedstocks, production, Hawaii 330.
tuberization, nutritional conditions affecting, Nebr. 195.
varieties, new seedling distribution, Me. 330.
varieties resistant to infection by veinbanding virus, 496.
variety resistant to blight, drought, and tipburn, Conn.[New Haven] 356.
variety tests, Alaska Col. 766; Colo. 104; Fla. 615, 626; Hawaii 330; Idaho 616; Mass. 474; N.Mex. 36; R.I. 767; S.C. 37; Tenn. 767; Wyo. 39.
vitamin C in, effect of storage, Wyo. 138.
washed, storage tests, Wash. 38.
yields and market quality, effect of soil reaction, 771.
yields at different dates following different treatment, Me. 330.
yields, effect of fertilizers, S.C. 37.
yields, effect of injured leaf surfaces by insects and diseases, 227.
yields, relation to manganese and other elements, Fla. 615.
Poultry—*see also* Chickens, Chicks, Ducks, Fowls, Hens, *etc.*
alfalfa and mixed pasture for, Mich. 616.
and eggs, Okla. 269.
artificial insemination, 326; U.S.D.A. 825.
autopsies, skin vaccination for, N.H. 546.
body weight, production, and egg weight, interrelation, 611.
breeding, Iowa 86.
breeding as factor in control of blindness and paralysis, 402.
breeding for lower adult mortality and high longevity and production, Wis. 466.
breeding stock, selection, N.J. 680.
brooders, electric, energy consumption, Ind. 118.
brooders, electric, insulated in uninsulated houses, Nebr. 260.
bumblefoot, acid-fast organisms found in, 101.
calcium combinations available to, Wis. 530.
capons and cockerels, comparison of growth rates and feed costs, Wis. 530.
carbon monoxide poisoning in, 827.
clubs, 4-H, manual for, Ill. 716.
confined v. range rearing, Idaho 676.
Congress, World's, notes, 288.
cost of production, N.J. 711.
costs in Michigan, Mich, 268.
crosses, sex-linked, 763.
crosses, variation and heredity of characters in, 763.
Poultry—Continued.
diseases—*see also specific diseases.*
and parasites in California, 546.

Proventriculitis, infectious, of turkeys, N. Dak. 537.
Provitamin D of plant and animal sources, 730; Ohio 389.
Prune—
cans, corrosion, effect of sulfur sprays, 585.
die-back, studies, 650.
russet, control, 800.
Prunes—
carbon dioxide treatment, effects, 347.
fertilization, Idaho 626.
fresh, cold stored, and frozen, vitamin C in, Idaho 726.
Sugar, fruit-bud differentiation in, 347.
vitamins in, 282.
Prussic acid poisoning by grain- and sweet-sorghum and Sudan grass, N.Dak. 537.
Psallus seriatus, see Cotton flea hopper.
Pseudaonidia duplex, see Camphor scale.
Pseudococcus—
brevipes, see Mealybug, pineapple.
comstocki, notes, 665.
inamabilis n.sp., description, 812.
lilacinus, notes, 808.
sociabilis, n.sp., description, 812.
spp. of economic importance in Brazil, 812.
tibouchinae n.sp., description, 812.
Pseudodiscosia avenae n.sp., description, 641.
Pseudogonatopus hospes, parasite of sugarcane leafhopper, Hawaii.Sugar Planters' 664.
Pseudomonas—
citri, see Citrus canker.
fragi causing rancidity in butter, Iowa 97.
phaseoli, notes, 364.
radicicola, see Nodule bacteria.
tumefaciens, secondary tumor formation induced by, 61.
Pseudoperonospora humuli on hops, 496.
Pseudopythium phytophthoron, notes, 506.
Pseudorabies, *see* Paralysis, infectious bulbar.
Public Works, programing, 270.
Puccinia—see also Rusts *and host plants.*
glumarum in Canada, 500.
glumarum on *Triticum* sp., 357.
helianthi, coalescing haploid pustules in, 217.
liberta, telia of, 209.
parksiana n.sp. on *Smilax vitiensis,* 209.
Pucciniastrum ericae n.comb., notes, 209.
Puerto Rico Station, report, 893.
Puerto Rico University, notes, 432.
Pulecephora sp., parasite of cotton leaf worm, 230.
Pullets—*see also* Fowls *and* Poultry.
effect of varying amounts of animal proteins, 681.
growth, effect of protein levels, N.C. 532.
Pullets—Continued.
growth rate, Mo. 86.
laying, effect of chronic coccidiosis, Mich. 691.
laying, presence of parasite causing coccidiosis in young chickens, Mich. 259.
management tests, 829; Ohio 389.
mortality, 259.
reared under confinement v. range conditions, egg production and mortality, Fla. 676.
Rhode Island Red, time interval between eggs, 533.
Pullorum disease—*see also Bacterium pullorum and Salmonella pullorum.*
acute and chronic form, and carriers, N.C. 109.
control, Idaho 690.
control in Mississippi, 401.
eradication in Massachusetts, 849; Mass. 537.
in chicks, effect of feeding colon organisms and dried whey, Fla. 690.
in turkeys, 101.
septicemic, in flock of adult fowls, 403.
studies, 259, 698; N.H. 546.
Pulping processes, alkaline, studies, 589.
Pumilus medullae n.sp., description, 222.
Pump irrigation at North Platte Experimental Substation, Nebr. 852.
Pumpkin—
and squash hybrids, studies, N.Y.State 608.
rot due to *Sclerotinia sclerotiorum,* 501.
seed, toxicity, 538.
Pumpkins—
canning qualities, factors affecting, Ind. 778.
varieties, Ind. 778.
Pumps and water wheels for irrigation, Mont. 701.
Purple scale—
control with lime-sulfur, 663; Fla. 658.
effect of freeze of 1934, 662.
Pyometra—
in cattle in Netherlands, 695.
role of *Trichomonas* in, 543.
Pyrausta nubilalis, see Corn borer, European.
Pyrethrin II, isolation, 661.
Pyrethrum—
and pyrethrum-nicotine sprays, new for white apple leafhopper, Mass. 512.
extract, notes, Mass. 512.
flowers, constituents, 100, 661.
flowers, fresh, pyrethrin in, 661.
flowers from various sources, pyrethrin in, 661.
fluid insecticide for combating infestation of imported stored products in warehouses, 660.
improvement, Colo. 197; Tenn. 779.
new strains, tests, Tenn. 779.
powder, absorption by roaches, mechanism, 514.

Pyrethrum—Continued.
preparation for control of nematodes, 370.
production, Ind. 778.
sprays, effect on housefly, 671.
Pyruvic acid, dissimilation by *Lactobacillus lycopersici*, 582.
Pythiaceous parasites at different soil levels, relation to fallowing practices, 494.
Pythium—
graminicolum on ginger, control, 208.
root rot, notes, Hawaii.Sugar Planters' 795.
rot of transplants, incidence, Conn.[New Haven] 356.
species affecting sugarcane, Iowa 55.
ultimum on potatoes, effect, 65.
Quackgrass control, Mich. 778.
Quail—
baby, *Salmonella* isolated from, 549.
bobwhite, northern, winter territory, Iowa 804.
bobwhite, wintering in Wisconsin and Iowa 373.
breeding, manual, 805.
Gambel, life history in Arizona, 373.
studies, Ind. 806.
Quince—
diseases in western New York, 305.
diseases, notes, 799.
rootstocks for pears, notes, N.Y.State 48.
rust, new on apples, 366.
seedlings, growing, new method, 781.
Rabbit—
papillomatosis, transmission by rabbit tick, 398.
plague, use of highly specific virus for control, 539.
pox, etiology and species susceptibility to virus, 398.
tick, transmission of rabbit papillomatosis by, 398.
Rabbitbrush in western North America, *Capitophorus* aphids infesting, 812.
Rabbits—
adult male, development of female characteristics in, 327.
American, effectiveness of Shope papilloma virus, 398.
birth weight, relation to litter size, and duration of gestation period, 612.
blood group inheritance in, 609.
eye defects in, production and inheritance, 609.
gestation period, 326.
inoculation with *Elsinoe ampelina*, 505.
management on small farms, U.S.D.A. 86.
nutritional requirements, Mo. 131.
wild, and field hare, differentiation, 467.
Rabies—
in South Africa, mammals concerned in, 397.
studies, 102.
Rachitis of chicks, factors affecting, Iowa 86.
Radiation—*see also* Solar radiation.
biological effects and mechanism and measurement, treatise, 757.
cooling of leaves by, 758.
phenomena in plants, 458.
Radio waves for insect control, 224.
Radioactive mud, effect on seed germination and growth, 25.
Radioactivity, effect on resistance to freezing in plants, 314.
Radish—
Fusarium disease, vascular, 495.
scarlet globe, shape, effect of planting depth, 627.
Radishes—
iodine in, Okla. 131.
magnesium requirements, Va.Truck 779.
Railletina—
cesticillus in poultry, Mich. 260.
echinobothrida of poultry, ant as intermediate host, 403.
Rain gauge support, U.S.D.A. 76.
Rainfall—*see also* Precipitation.
conservation in New Mexico, N.Mex. 403.
conservation through soil and crop management, 331.
distribution in Puerto Rico and Virgin Islands, 443.
forecasting, relation to tobacco planting in Java, 746.
in South Africa, 853.
relation to flood run-off, 12.
Rains, spring, effect on agriculture in Italy, 12.
Rainwater, solubility of calcic and magnesic materials in, Tenn. 747.
Raisin moth larvae, large numbers, rapid method for estimation, U.S.D.A. 511.
Raisins, vitamins in, 281.
Ram, short-tailed Hampshire, breeding record, Nebr. 239.
Ramie, production tests, Fla. 615; Miss. 331.
Rams—
development of testicle and tunica dartos muscle, Mass. 612.
foul sheath in, cure with copper sulfate, Idaho 690.
Ranch and range balance, Nev. 271.
Range—
cattle problems of Florida, 527.
character, relation to grazing practices, N.Dak. 520.
Experiment Station, Dominion, in British Columbia, 143.
grasses, *see* Grasses.
improvement, Colo. 194.
plants, poisonous, *see* Plants, poisonous, Livestock poisoning, *and specific plants*.
Raspberries—
akala, hybridization, Hawaii 339.
black, breeding for anthracnose resistance, Iowa 44.
black, leaf bud cuttings, propagation, Iowa 44.
black, mosaic, Wash. 58.
black, straw mulch for, Ohio 340.

Raspberries—Continued.
breeding, Tenn. 779; Wash. 46.
chromosome behavior in, Tex. 45.
Columbian purple, carries mosaic virus, N.Y.State 650.
culture, N.J. 627; Tenn. 779.
culture experiments, Alaska Col. 778.
fertilizer requirements, 630; R.I. 779.
fertilizers for, effects, 630.
frozen and thawed, vitamin C in, Wash. 136.
Taylor, characteristics, N.Y.State 50.
varieties, Me. 340.
variety tests, Mont. 626; Wis. 483.
winter injury in, detecting, N.Y.State 204.
Raspberry—
and blackberry hybrids, chromosome behavior in, 465.
beetle, control, 807.
gall tissue cells, effects of cane gall bacteria, 367.
green mottle mosaic, proposed name, 504.
insects, problems of, 808.
leaves, absorption of water by, 486.
mosaic and related diseases, Wash. 69.
mosaic, control, 801.
mosaic, English, in Oregon, U.S.D.A. 356.
mosaic, sources of infection and control, 368.
mosaic types, identity, 504.
spur blight, studies, N.J. 638.
virus disease control, Ohio 222.
Rat flea, oriental, role in typhus transmission, 694.
Rat poison in antiplague work, choice, 804.
Rations, balancing in respect to proteins, 528.
Rats—*see also* Rodents.
and guinea pigs, development of gonadotropic response, similarity, 766.
fasting, metabolism of, 279.
hypophysectomized female, gonadotropic effects of implants of pituitaries from castrated males, 327.
lactation in, studies, 421.
on vitamin G-deficient diet, pathological skin changes in tail, 888.
sexual development, effect of retarded growth, 677.
spontaneous virus diseases in, 540.
Real estate—*see also* Farm real estate.
prices and transfers, Ind. 863.
Reclamation, place in national agricultural program, 702.
Recreation, rural emergency, and future rural social planning, 713.
Recreational—
and scenic resources of Utah, survey, 716.
facilities, development, Ohio 353.
Red gum fire scars, protective zone in, 508.
Red mite, citrus, control in California, 234.
Red mite, European—
control, 662.
on prunes in western New York, 674.
summer control on apple, 674.
Red scale—
California—
effect of oil spray at various stages, Calif. 666.
fumigation, substitutes for hydrocyanic acid in, 666.
methyl thiocyanate v. hydrocyanic acid as fumigant, 518.
resistant and nonresistant to hydrocyanic acid gas, 228.
Florida, effect of freeze of 1934, 662.
in Palestine, control, 813.
Red spider—
control, 662.
control in orchards, Wash. 79.
control with naphthalene, Mass. 225.
development and control, effect of temperature, Mass. 512.
notes, Ohio 374.
Red squill—
extracts as raticides, effectiveness, Mass. 510.
properties, toxicity, and palatability to rats, 509.
Redwater, Rhodesian, *see* African coast fever.
Redwood from gefle and archangel, strength tests, 262.
Reed canary grass—
as pasture crop, Mont. 684.
consumption by grazing steers, 527.
culture experiments, Iowa 35.
seed, harvesting and threshing tests, Wis. 475.
Reforestation—
activities, Ohio 352.
natural, in absence of fire and grazing, S.C. 53.
Refrigeration—
electric, and air conditioning, 734.
farm, methods, N.Dak. 575.
Refrigerators, kerosene-burning mechanical, N.Dak. 549.
Relapsing fever—
tick transmitter, host relations, 810.
transmission by ticks in Palestine, 255.
Relief—
families in rural Tennessee, mobility, 873.
in coal mining community, Grundy County, Tennessee, 875.
rural, and rehabilitation possibilities in Tennessee, 873.
rural, concentration in certain localities in North Carolina, 715.
Rennet for detection of mastitis, 845.
Reproduction—
hormones involved in, 326.
in sheep and swine, physiology, Mo. 33.
in sheep, physiology, 469.
Reproductive—
organs, female, endocrinology of, 469.

Reproductive—Continued.
organs of rabbit during pregnancy, changes in, 469.
phenomena, control, hormonal mechanisms in, 469.
Reptiles of Costa Rica, 805.
Research—*see also* Agricultural research.
laboratories, regional, under Bankhead-Jones Act, editorial, 1.
Reservoirs, capacities, formula for, 405.
Resettlement—
Administration, aims and objectives, 268.
rural, needed standards of living for, 714.
Resin—
content of leafy trees, effect of climatic conditions, 180.
total neutral and unsaponifiable matter in, 304.
Respiration—
and carbon fixation of plants, apparatus for measuring, 182.
of cows, effect of temperature, 99.
of plants, 312.
of plants, effect of petroleum oils, 603.
of plants, effect of ultraviolet light, 27.
rate of cherry laurel and mechanical stimulation, 28, 29.
studies, 456.
Respiratory diseases of poultry, [Conn.] Storrs 252.
Reticulitermes flavipes—
damage from, Conn.[New Haven] 657.
injury to buildings in Connecticut, 227.
Reticuloendothelial proliferations in domestic animals, 540.
Rhabdepyris zeae, parasite of *Tribolium*, U.S.D.A. 524.
Rhabditis spp. in forest nurseries, nematodes affecting, 509.
Rhabdoconemis obscura, *see* Sugarcane weevil, New Guinea.
Rhagoletis—
cingulata, *see* Cherry fruitfly.
pomonella, *see* Apple maggot.
Rhinitis, infectious, of swine, 397.
Rhipicephalus—
bursa, vector of new Rickettsia of sheep, 400.
sanguineus, *see* Dog tick, brown.
Rhizobium—
growth and longevity on agar containing various energy sources, 187.
growth rate, 186.
growth stimulants for, 187.
physiological studies, Iowa 15.
spp., effectiveness, relation to host plant, 320.
spp. in pure culture, nitrogen fixation by, 456.
spp., response to natural humic acid, 600.
Rhizoctonia—
batatícola, notes, 362.
control on seed potatoes, 644; Me. 357.
Rhizoctonia—Continued.
infection of potatoes, Fla. 636.
solani—
damping-off of citrus seedlings due to, Calif. 70.
effect of chloropicrin as soil fumigant, 638.
grass hosts other than rice, 207.
in pure culture, production of sclerotia by, 363.
in turf, control by fanning, 495.
on *Matthiola* in Victoria, 369.
physiology, 61.
species affecting sugarcane, Iowa 55.
Rhizopus nigricans, toxicity of dyes to, 606.
Rhode Island Station, report, 893.
Rhododendron—
wilt and root rot due to *Phytophthora cambivora*, U.S.D.A. 789.
wilt, control, N.J. 638.
Rhododendrons, winter forcing, R.I. 779.
Rhodoneura locusalis, life history, 816.
Rhodophyceae, life history, 320.
Rhopalosiphum pseudobrassicae, *see* Turnip aphid.
Rhopobota naevana, *see* Fireworm, blackheaded.
Rhubarb—
beverages from, 718.
raw, cooked, and canned, vitamin C in, Mass. 563.
roots, effect of fungicidal treatments, N.J. 638.
tests, Alaska Col. 778.
use for jelly, N.Dak. 564.
vitamin C in, N.Y.State 728.
Rhyacionia—
buoliana, *see* Pine shoot moth, European.
frustrana bushnelli, studies, U.S.D.A. 77.
frustrana, control, U.S.D.A. 511.
neomexicana, studies, U.S.D.A. 77.
spp., notes, 669.
Rhynchocoris serratus, biology and control, 228.
Rice—
and rice byproducts for fattening swine, Tex. 88.
border effect on field and nursery plats, Tex. 38.
borer, Asiatic, population density, 231.
bran, added to basal ration, effect on growth rate and slipped tendon in chicks, 828.
bran extracts and growth of micro-organisms, 754.
bran for cattle fattening, Tex. 88.
bran paste, analyses, Hawaii 415.
breeding, Tex. 38.
bunt, 207.
chlorosis induced by iron deficiency, 496.
culture and changes in oxidation-reduction equilibrium in soils, La. 308.
culture experiments, Tex. 38.
diseases in British Guiana, 357.

Rice—Continued.
fertilizer experiments, Hawaii 330; Tex. 38.
inheritance studies, Tex. 38.
natural crossing in, Tex. 38.
new or little-known *Fusarium* disease, 207.
on flooded soils, toxicity from arsenic compounds, 772.
outlook charts, U.S.D.A. 120.
seed, effect of continuous submergence, Tex. 38.
seedling blight disease, control, 787.
stubble, pasture crops on, Tex. 38.
under submerged condition, phosphatic fertilization, 471.
weevil on corn, S.C. 78.
weevil, oviposition, effect of temperature and humidity, 385.
Rickets—
blood buffer capacity in, 567.
development through overdosage of iron, Wis. 564.
in dairy calves, histological changes in, Mich. 536.
prevention with cod-liver oil concentrate in milk, 430.
Rickettsia of sheep, new form, description, 400.
Rickettsioses and etiological agents, criteria for accurate classification, 603.
Rift Valley fever, studies, 102.
Rinderpest—
biological products used against, 538.
changes in composition of organs during, 103.
pathological anatomy of spleen in, 104.
properties of blood in, 103.
studies, 102.
vaccine, studies on glycerinized spleen pulp, 695.
virus in goats, experimental study, 697.
virus, permeability of placenta of goats to, 104.
River stages, daily, at gage stations, U.S.D.A. 111.
Road—
surfaces, oil-gravel mixtures for, Colo. 200.
tars, studies, U.S.D.A. 854.
Roads—
construction costs, indexes, U.S.D.A. 552.
stabilized soil, U.S.D.A. 552.
Rock phosphate, *see* Phosphate.
Rocket, garden, a new flax weed, 482.
Rocky Mountain spotted fever in Maryland, 540.
Rodents—*see also* Mice *and* Rats.
as pests in bulb plantings, U.S.D.A. 72.
control, Ohio 202.
mouse-like, fluctuations in numbers, causes, 72.
new tick collected from in Wyoming and Washington, 819.
of North Carolina, parasites, 804.
Rodents—Continued.
prevalence and control under field and village conditions, Fla. 658.
Roentgen rays, *see* X-rays.
Root—
formation on stem cuttings, relation to hormones, 186.
hairs, production, relation to development of piliferous layer, 319.
knot nematode—
galls, development, 509.
new hosts for, U.S.D.A. 207.
notes, Fla. 637.
resistant variety of cowpea, 495.
starving out, Fla. 636.
knot, susceptibility of ornamentals to, Fla. 223.
maggot control with calomel, N.Y.State 228.
nodules, of *Alnus* and of *Elaeagnus* and *Hippophae*, cause, 187.
rots of strawberry and tobacco, microscopical study, 355.
tips, excised, growth studies, 456, 605.
Roots—
analyses and digestible nutrients, U.S.D.A. 821.
excretion of organic acids by, 186.
secondary, initiation and growth induced by growth substances, 456.
Rootstocks, mazzard and mahaleb, comparison, Tenn. 779.
Rope, wire, use, 264.
Rosa and closely related genera, morphology of flowers, 320.
Rose—
beetle, Fuller's ovipository for, U.S.D.A. 77.
black spot, control, 494, 652, 653; N.J. 638.
black spot, red copper oxide spray for, 653.
brown canker, control, N.J. 638.
die-back, control, 494.
diseases, Tex. 57.
diseases in Florida, control, Fla. 637.
plants, defoliation, effect of certain chemicals, 494.
powdery mildew, control, 652, 653.
sawfly, bionomics, 386.
seeds afterripening and germination, 351.
Roses—
greenhouse, control of black spot on, 653.
sand culture, N.J. 627.
spray experiments for control of black spot and powdery mildew, 652.
summary, Ind. 634.
thornless, production by South Dakota Experiment Station, 493.
Rotation of crops, Alaska Col. 766; Idaho 616; La. 474; Mo. 15; Nebr. 195; R.I. 767; Tenn. 767; Tex. 38; Wash. 38; Wyo. 39.
Rotation of crops on dry land and under irrigation, Mont. 616.

Rotation of crops under irrigation, U.S.D.A. 617.
Roughages—
carbonaceous, feeding value, Colo. 531.
dehydrated, value in dairy ration, N.J. 684.
effect on vitamin D in milk, S.Dak. 684
high quality, value for economical milk and butterfat production, Mont. 684.
in fattening ration for steer calves, 527.
Swedish, ash constituents, 236.
Roup—
in chickens, Wyo. 103.
prevention with home-made virus, 401.
vaccination, Mich. 691.
Rubber moldy rot, control, 372.
Rubbertree diseases and pests, 208, 507.
Rudbeckia bicolor, response to day length and temperature, 755.
Rue, African, toxicity tests, N.Mex. 691.
Run-off—
and erosion experiments in mountain and cultivated areas, 702.
conservation, value of terracing, contour farming, and strip farming, 331.
from small experimental plats, 702.
in South Africa, 853.
losses, relation to crop production and soil erosion, Tex. 111.
Rural
areas, localization of dependency in, 715
community in United States as an elementary group, 714.
credit, *see* Agricultural credit.
discussion groups, organization and conducting, manual, Ill. 277.
indebtedness situation in Puerto Rico, P.R.Col. 710.
labor, *see* Agricultural labor.
life and agriculture, arithmetic in, treatise, 277.
organization, participation of farm people in, Ill. 501.
public welfare and national policy, 713.
rehabilitation program, 208.
schools, *see* Schools, rural.
social organizations and national policies, 713.
standards of living, *see* Standards.
youth, activities, interests, and problems of young married people, [N.Y.] Cornell 501.
Rush, horned, smut on, Tex. 57.
Rust mites—
control with lime-sulfur solution, 668.
effect of freeze of 1934, 662.
Rusts—*see also* Cereal rusts *and specific hosts.*
miscellaneous notes, 209.
Rutabagas, *see* Swedes.
Rye—
and wheat amphidiploid, chromosome differences in, 190.
as feed for dairy cattle, Mont. 684.
as poultry feed, 389.
breeding, N.J. 616.
culture experiments, Tenn. 767.
in laying rations of hens, Wyo. 89.
interspecific hybrids, Wash. 38.
nitrogen fertilization on sandy soils and peat soils, Wis. 445.
outlook charts, U.S.D.A. 120.
seed, State certified, N.J. 330.
sowing on bluegrass and Bermuda sod, Tenn. 767.
varieties, acre yields, Ind. 767.
varieties, introduction, testing, and distribution, Mont. 616.
variety tests, Ga.Coastal Plain 194; S.C. 37; Tenn. 767; Wash. 38.
winter, effect of late frosts, 337.
yields, Ind. 767.
Ryegrass, susceptibility to *Rhizoctonia solani*, 61.
Saccharomyces aceris-sacchari and *Pichia alcoholophila*, dissociation, 606.
Safflower oil meal v. linseed meal, feeding value, N.Dak. 529.
Sage cheese, manufacture, N.Y.State 101.
Sage chickens as carriers of coccidiosis, Wyo. 103.
Salmon—
byproducts, utilization by poultry, Wash. 88.
canned, vitamins A and D in, 884.
oil, feeding to cows, effect on composition of blood and milk, 685.
Salmonella—
aertrycke type of organism in turkeys, 700.
aertrycke, typhoidlike disease in laboratory animals due to, Iowa 102.
enteritidis, varieties, 540.
inoculated eggs, hatchability, 260.
isolated from baby quail, 549.
pullorum—*see also Bacterium pullorum and* Pullorum disease.
carriers, detection, comparison of tests for, Miss. 548.
cause of arthritis, 699.
in eggs from infected hens, 698.
resistance to action of disinfectants, 699.
variation in, 699.
suipestifer, spontaneous infection of swine, 401.
suipestifer strains, phages for, variations in, 105.
Salmonellosis of webfooted fowl, 850.
Salsify, transition region, anatomy and histology, 629; Ohio 340.
Salt, coarse, toxic effect on potatoes, 215.
Salt, effect on silk, 139.
Salt requirements of poultry, 825.
Salts—
absorbed by seeds, leachability, 316.
and amino acids, interaction, 294.
inorganic, in nutrition, 881.
Saluyot—
tender leaves and tops, vitamin B_1 in, 571.
vitamin A in, 571.

San Jose scale—
control with creosote oil, 373, 787.
dinitro-o-cyclohexylphenol in petroleum oil for, tests, 225.
toxicity of substances to, method of comparing, 518.
Sand culture—
apparatus, 179.
of seedlings for damping-off control, Conn.[New Haven] 43.
Sandal spike disease, entomological studies, 79, 813.
Sanitation, rural, 267.
Santol fruit, vitamin B_1 in, 571.
Saperda—
candida, *see* Apple tree borer, roundheaded.
tridentata, *see* Elm borer.
Sarcomatosis and fowl leucosis produced by same virus, 547.
Sarcophaga lambens, parasite of cotton leaf worm, 230.
Sauer rüben, production, U.S.D.A. 745.
Sawflies, natural history, 656.
Sawfly—
biologies, 819.
black wheat-stem, Ohio 374.
European, on mountain ash in United States, 512.
fauna, British, alien element in, 387.
Sawmills—
financing and operation, U.S.D.A. 704.
small, improvement, U.S.D.A. 113.
Scab gnat injuries to potato tubers, 662.
Scale—
insect, new to Connecticut, Conn.[New Haven] 374, 657.
insects on citrus, control, Tex. 78.
insects, spray for, Wash. 79.
Schistocerca gregaria—
on Red Sea coast of Sudan, outbreak centers, 377.
notes, 377.
Schleichera trijuga, insect pests of, 809.
Schools—
high, health service of Idaho, Idaho 716.
rural, consolidation, savings resulting from, Iowa 119.
rural elementary in Iowa, reorganization, Iowa 875.
Science in modern life, 134.
Sciodopitys verticillata, fertilizers for, R.I. 779.
Sciopithes obscurus on strawberries, Oreg. 232.
Scirpophaga nivella in Punjab, 79.
Scirtothrips—
citri, *see* Citrus thrips.
dorsalis, biology and control, 81.
dorsalis, cause of chili leaf curl, 79.
Scleroderma immigrans, parasite of *Tribolium*, U.S.D.A. 524.
Sclerophoma blight of Texas bluebells, control, Tex. 57.
Sclerotinia—
fructicola
conidia, absorption of copper of bordeaux mixture residues, 499.
germination, relation of temperature to effect of pH, Ohio 498.
infection studies, 495.
spore germination and growth, effect of temperature and pH, Ohio 357.
minor causing collar rot of *Primula malacoides*, 370.
minor, notes, N.J. 638.
rot of potatoes in Florida, 788.
sclerotiorum, notes, Fla. 636; U.S.D.A. 356.
sclerotiorum rot of squash and pumpkin, 501.
spp., apothecia of, 221.
trifoliorum, new host species, 212.
Sclerotium—
bataticola as seed-borne organism, Tex. 57.
delphinii, notes, 370; U.S.D.A. 636.
rolfsii, effect of chloropicrin as soil fumigant, 638.
rolfsii in Florida, host relations and pathogenicity, Fla. 637.
rolfsii, notes, 207.
rolfsii on strawberries and effect of chemicals on *Sclerotia*, 788.
rolfsii, pathogenicity for young apple trees, 496.
Scolytus—
multistriatus—
associated with spread of Dutch elm disease, 231.
trap-log studies, 524.
vector of Dutch elm disease, 371.
sulcatus on apple and elm bark beetles in New York State, 224.
Screwworm fly, primary, biology, U.S.D.A. 82.
Screwworms—
comparison, U.S.D.A. 82.
emergency studies, Iowa 77.
Scrotum of rams and bulls, development, Mass. 466, 612.
Scutigera forceps, *see* Centipede, house.
Seed—
analyst, young, training, ideas, and future, 626.
label, uniform, 626.
law enforcement, 625.
stocks, poor, detection by testing and control fields, N.Y.State 141
Testing Congress, International, notes, 288.
treatment with fungicidal dusts, studies, 787.
Seedbed, preparation, studies, Wyo. 39.
Seed-corn maggot—
studies, Tex. 78.
vector of Stewart's disease, Mich 642.
Seedlings, culture in sand to prevent damping-off, 639.

Seeds—
aged and injured, germination studies, 196.
analysis for purity and germination, technic, Iowa 35.
dehulled, viability, N.Dak. 475.
dusted, drilling problem and value of graphite, 494.
effect of nitrate poisoning, 317.
flower, quality on sale in New York, N.Y.State 205.
germinated, transfer from blotters to field soil, 626.
germination and growth of seedlings, effects of radioactive mud, 25.
germination, effect of moist substratum, 625.
germination, effect of sulfureous mineral waters, 317.
hard, viability, testing, 625.
inspection, Ind. 43; Mass. 197; Me. 197; N.J. 339.
leachability of salts absorbed by, 316.
misbranded, and seedling identification, 625.
oil, *see* Oil seeds.
packet, studies, Mass. 483.
purity and germination tolerances same problem, 626.
ripening, effect of date of maturity and temperature on organs of seeds and on seedlings, 182.
sand cultures for damping-off control, Conn.[New Haven] 43.
State certified, definition, N.J. 339.
statistics, U.S.D.A. 197.
testing for purity and germination, Mont. 616.
testing, papers on, 625.
vegetable, on sale in New York, quality, N.Y.State 198.
vitality, soil work for testing, 625.
weed, *see* Weed seeds.
Segadilla pods, vitamin A in, 571.
Selenium—
as catalyst in determination of protein in wheat, 9.
in Colorado River and tributaries, 581.
in dormant sprays, 512.
in natural phosphates, superphosphates, and phosphoric acid, 176.
in organic matter, determination, 440.
in plants and soils, Wyo. 103.
in proteins from toxic foodstuffs, effect of acid hydrolysis, 237.
in proteins from toxic foodstuffs, nature, 90.
in soil, effect of sulfur on toxicity of wheat from such soil, 842.
in sulfur, determination, 441.
intoxication, alkali disease due to, S.Dak. 691.
poisoning, mechanics, relation to enzyme systems, Wis. 538.
Senecio spp., morphology, 458.
Septicemia, hemorrhagic—
biological products used against, 538.
in cattle and swine, Fla. 690.
progress in, S.Dak. 691.
Septobasidium, new species on cedar elm, Tex. 57.
Septoria—
cucutana n.sp. on leaves of *Tecoma pentaphyllae,* 208.
leaf spot of chrysanthemums, control, 652.
leaf spot of peony in Oregon, U.S.D.A. 207.
unedonis on *Arbutus unedo,* U.S.D.A. 496.
Serica sericea, life history, 383.
Serum, pregnant mare's, effect on immature fowl, 329.
Serums, normal, cercaricidal action, 694.
Sesamum, photoperiodism in, 313.
Sesbania, root rot on, Tex. 58.
Setaria bidentata from Trinidad deer, 654.
Sewage—
chlorination studies, N.J. 409.
sedimentation and soil purification in tropics, 267.
studies, N.J. 702.
Sex—
characters in chicks, effect of hebin injections, 469.
differentiation in day-old ducklings, 683.
glands, relation to sex differentiation in feathering of fowls, 469.
hormone, female, vitamins in, 469.
hormone, male, bill of sparrow as indicator for, 328.
hormone, male, standardization, 325.
hormones—
assay, 469.
in pregnant mares' urine and serum, 325.
origin in urine of pregnant sows, 325.
physiological reaction in, 469.
so-called, extracted from urine, 469.
standardization, 33.
Sexual—
life in fowls, endocrine factors, 326.
maturity in fowls, effect of pregnant mare's serum, 329.
system, female, and thyroid gland, mutual relation, 469.
Shark oil, feeding to cows, effect on composition of blood and milk, 685.
Sheep—*see also* Ewes *and* Lambs.
border pining, 695.
botfly, *see* Botfly, sheep.
breeding, N.H. 529.
breeding for taillessness and quality of fleece, S.Dak. 609.
breeds most suitable for Tennessee, Tenn. 820.
Columbia, adaptability to Florida conditions, Fla. 675.
Corriedale, adaptation to southwest Texas conditions, Tex. 88.

Sheep—Continued.
death losses on areas infested with pingue, prevention, N.Mex. 846.
digestibility experiments, Wash. 98.
diseases—*see also specific diseases.*
caused by anaerobic bacteria, 252.
feeding experiments, N.Dak. 530.
fertility in, artificial production of seminal ejaculation and characters of spermatozoa, 822.
fly-struck, glycerin-boric acid dressings for, 400.
foot rot, control, Mont. 691.
gastrointestinal parasites, treatment with copper sulfate and salt, W.Va. 847.
genetic studies, Tex. 32.
genetics, summary, 467.
growth of skin area, 528.
hemolytic streptococci in tonsils, 841.
improvement by crossbreeding, Wyo. 89.
intersex, studies, 193.
judging age from teeth, Mont. 678.
Karakul, gray hair color of, 467.
losses in the feed lot, Tex. 103.
market classes and grades, U.S.D.A. 389.
marketing data of Canada, 276.
Merino, wool fat and suint in, distribution, 240.
mountain, crossing with domesticated type, Alaska Col. 819.
outlook charts, U.S.D.A. 120.
parasitoses of economic importance, [Conn.]Storrs 252.
physiology of reproduction in, 469.
poisoning, *see* Livestock poisoning, Plants, poisonous, *and specific plants.*
pox, biological products used against, 538.
pox, studies, 102.
pregnancy disease of, N.Dak. 537.
production changes from planned utilization of land, 528.
Rambouillet, fleece weight, relation to skin folds, Tex. 88.
range, oak poisoning in, 842.
reproduction in, physiology, Mo. 33.
tick-borne fever of, 397.
Toushi, biological importance of fat tail, 192.
variations in rib number and asymmetry of thorax, 192.
wool characters in crosses, 762.
wool characters in, inheritance, 762.
Shelterbelts—*see also* Trees, shelterbelt.
types, windbreaking effects, 784.
Sherbet, storage studies, 252.
Shrew, short-tailed, biology, 72.
Shrimp—
arsenic compared with arsenic trioxide metabolism in rats, 884.
meal for milk production, 527.
Shrubs—
evergreen, of Colorado, leaf anatomy, 187.
grown on prairie soils, root systems, 180.
Shrubs—Continued.
introduced, winter injury, Fla. 626.
propagating, comparisons of soil materials, Wis. 483.
propagation for possible erosion control value, Iowa 53.
variety tests, Mont. 626.
winter-injured, frost ring formation, 313.
Silage—
alfalfa-timothy hay, analyses, N.J. 684.
analyses and digestible nutrients, U.S.D.A. 821.
corn and sorgo combination, tests, Tenn. 767.
corn, cost of production, N.J. 711.
corn, vitamin D in, Mich. 683.
corn, vitamin D in various portions of plant used for, Mich. 236.
crops, 331.
crops, comparative production, Fla. 616.
feeding, light v. heavy, for fattening steers, Idaho 676.
from cull apples and cull apples and alfalfa, feeding value, Wash. 98.
from legumes and mixed grasses, preparation with molasses, 684.
from mature v. immature corn, N.Dak. 520.
grainless, feeding value, Nebr. 239.
grass, as means of growing more feed units, N.J. 684.
grass, value in dairy ration, N.J. 684.
mung bean, digestibility and composition, silica-ratio procedure for studying, 820.
oat and pea, green stacked, feeding value, Wash. 98.
pea vine, as feed for dairy cattle, Mont. 536.
potato, feeding value, Colo. 531.
rations, nutritive value, Wash. 98.
rations, supplements for beef cattle, Nebr. 239.
sorghum, feeding value, Fla. 675.
soybean, feeding value, Colo. 531.
soybean v. corn with soybeans, S.C. 37.
sunflower, feeding value, Colo. 531.
Silk—
effect of salt, 139.
production, Mich. 268.
weighting, Minn. 734.
Silks, weighted, deterioration by solutions, Iowa 139.
Silos—
capacity, Mo. 111
temporary, N.Dak. 549.
temporary crib, Ind. 851.
trench, efficiency, Fla. 675.
trench, value, La. 534.
Sires—*see also* Bulls.
progeny test for dairy cattle, 608.
proved, continuous use for maintaining high production, Idaho 683.
proved for production by Dairy Herd Improvement Association, U.S.D.A. 686.

Sirups—
mineral content, Miss. 879.
table, manufacture from sugarcane, P.R. 745.
Sitophilus—
granaria, see Granary weevil.
oryza, see Rice weevil.
Skim milk—
Babcock testing and other methods of analyzing, Nebr. 697.
dried, added to pigs ration, Ohio 388.
dried, vitamin G in, effect of process of manufacture, 251.
need of large quantities for gilts, Wis 530.
powders, nutritive value, 235
testing by Babcock test, Mo. 246.
Sky, brightness, apparatus for measuring, 161.
Slash pine, establishing on poorly drained soils, S C. 53.
Slug, black European, as tobacco pest, U.S.D.A. 655.
Smilax leaf spot and canker due to *Fusarium* sp., N.J. 638.
Smoke column, visibility, effect of direction of illumination, 54.
Snails—
hosts of causative agent of dermatitis, 805.
Lymnaea, as first intermediate hosts of trematodes, 103.
Snapdragon—
black crown rot, 788; Tex. 57.
rust in western Germany, 507.
Verticillium affecting, U.S.D.A. 356.
Snapdragons—
breeding for varietal improvement and disease resistance, Mass. 483.
soil reaction for, Ohio 340.
Snow—
barriers, permanent, use of evergreens for, Wis. 483.
cover in wintering of crops, 305.
surveys in Great Plains area, methods and results, 702.
Soap washes and oil emulsions as summer sprays for peach, 514.
Soaps as spreaders of lead arsenate, Wash. 79.
Social—
organizations, rural, and national policies, 713.
planning, rural, and recreational programs, 713.
planning, yardsticks for, 714.
standards for southern farmers, 714.
Society of American Bacteriologists—
meeting, abstracts of papers, 320.
North Central Branch, proceedings, 187.
Sociological implications of agricultural adjustment program, 713.
Sociology, rural—
research by Michigan Station, Mich. 713.
studies, Ohio 415; Wis. 560.
treatise, 713.
Sodium—
bicarbonate, injurious effect on chicks, 828.
chlorate, use in weed control, problems connected with, 482.
chloride—*see also* Salt.
activity of coefficient, effect of amino acids, 294.
fluoride as food poison for firebrat, 525.
nitrate, boron and manganese in, adequacy to support plant growth in sand culture, N.J. 462.
nitrate, brands, tests, S.C. 37.
nitrate, effect on micro-organisms, Colo. 168.
nitrate, effect on nodule numbers and growth in alfalfa, 451.
nitrate, rates of applying for side dressing on cotton, S.C. 37.
replaceable, effect on index of friability of soil, 175.
small amounts, rapid centrifugal estimation, 7.
Soil—
acidity—*see also* Lime, Limestone, Liming, *and* Soils, acid.
effect of crops, R.I. 747.
increase with depth of tropical soils, 168.
analysis, aggregate, direct method, 592.
analysis, mechanical, development, 163.
analysis, mechanical, two methods, 592.
bacteria, activity, effects of soil treatments, Mo. 15.
bacteria and higher plants, symbiotic relations, 173.
bacteria, lytical action on parasitic fungi, 498.
bacteria, reproduction in soils stored at 25° and 7° C., Mich. 592.
blowing, control in Colorado, Colo. 112.
changes resulting from nitrogenous fertilization, Conn.[New Haven] 751.
colloids, *see* Colloids.
Conservations and Domestic Allotment Act, Okla. 412.
conservation—
area, Spencer, social and economic survey, W.Va. 414.
in an improved agriculture, Mo. 404.
in New Mexico, N.Mex. 403.
research in, Iowa 852.
use of terracing plow for, 408.
control, cropping methods for, 471.
crusts, 404.
crusts, strength, and method of overcoming injury to cotton stand, 472.
deficiencies and their correction, 473.
Erosion and Moisture Conservation Experiment Station, Pacific Northwest, Wash. 112.
erosion—
and run-off experiments from cultivated and mountain areas, 702.
control, 702; Ind. 851.

Soil—Continued.
erosion—continued.
control, a basic reconstruction problem, P.R. 853.
control, cropping systems in relation to, Mo. 853.
control in United States, 170.
control on mountain roads, U.S.D.A. 405.
control on southwestern ranges, vine-mesquite for, U.S.D.A. 113.
control, proposed system, 471.
control with S. E. R. A., 261.
experiments, 474.
in Iowa, survey, Iowa 852.
in South Africa, 853.
index variants, 471.
losses from soil fertility plats, Ohio 306.
losses, physical nature, 592.
problem, facing, 473.

Sows, brood—
rations for, Mo. 86.
self-feeding, Tex.
value of soybeans for, Ind. 819.
Soybean—
diseases and pests, 364.
flour as milk substitute for calves, 686.
hay cut in different stages of maturity, effect on vitamin A in butter, 245; Ind. 831.
hay, feeding value, Ind. 834.
hay from different varieties, protein in, Ohio 331.
laboratory under Bankhead-Jones Act, 2.
mosaic virus, identification, 62.
oil meal—
effect of method of preparing on value as protein supplement for pigs, Wis. 530.
expeller processed, and other protein supplements, comparison, 528.
feeding value, Hawaii 388; Kans. 531.
in broiler rations, Ind. 820.
properly prepared, value for poultry, Wis. 530.
projects of State agricultural experiment stations, U.S.D.A. 195.
seed and oil characteristics, effect of variety, maturity, and soundness, 473.
seed, State certified, N.J. 339.
seed, viability, effect of storage conditions, 625.
Soybeans—
and soybean products for table use, U.S.D.A. 566.
breeding, Iowa 35; Mo. 36; Tex. 38; Wash. 38; Wis. 475.
culture experiments, Ga.Coastal Plain 194.
development, effect of length of day, Mo. 756.
edible, variety tests, S.C. 37.

Soybeans—Continued.
effect of applying fertilizers directly, Ohio 331.
effect of vernalization, 185.
effect on pork quality, Ind. 819.
efficiency of free and combined nitrogen for, Wis. 445.
fed with corn to avoid soft pork, S.Dak. 677.
for grain and hay, acre yields, Ind. 767.
ground, as protein supplement for laying hens, Del. 532.
growth, nodulation, and composition, factors affecting, Mo. 42, 773.
interplanted with corn and variously spaced, La. 474.
introduction into Missouri, Mo. 36.
Kingwa and Pekwa, W.Va. 773.
nitrogen fixation by, 471.
nitrogen fixation by, effect of exchangeable calcium, 599.
nodulation, effect of length of day and soil temperature, 157.
nutritive value and mineral deficiencies, Ind. 819.
outlook charts, U.S.D.A. 120.
photoperiodism, relation to composition and enzyme activity, Mo. 45.
selection and response to fertilization, S.C. 37.
utilization, Ind. 745.
varieties, response to day length and temperature, 755.
variety tests, Fla. 615; Ga.Coastal Plain 104; Hawaii 330; Iowa 35; La. 474; Mo. 36; N.Mex. 36; Nebr. 195; R.I. 767; S.C. 37; Tex. 38; Wis. 475.
variety tests for grain and hay, N.J. 616.
whole, value for fattening calves, Iowa 86.
Spanish-moss examination for cotton insects, S.C. 78.
Sparrows, pigmentation of bill as indicator for male sex hormone, 328.
Sperm, avian, preparation of smears for microscopy, 765.
Spermatozoa—
abnormal, in semen of boars, Mass. 466.
obtaining from male birds and technic of artificial insemination, U.S.D.A. 825.
of horse, preserving motility, 326.
rate of travel in ewes, 469.
speed of travel in vitro and in uteri of ewes, Mass. 466.
Sphaceloma—
fawcettii, generic status, 505.
fawcettii scabiosa in Australia, 506.
sp. on a remote citrus relative from India, 368.
Sphaceloma and *Sorosporium reilianum*, hybridization between, 496.
Sphaeronema sp., isolation from black knots, 68.
Sphaerophthalma myrmicoides, notes, Minn. 674.
Sphaeropsis—
ellisii cromogena n.v., cause of timber stain in pine, 372.
malorum on *Abies concolor*, U.S.D.A. 55.
Sphinx—
gordius, studies, Mass. 512.
pinastri, development, effect of temperature and humidity, 656.
Spider, black widow—
experimental studies, 387.
morphology, biology, etc., Ark. 387.
notes, Conn.[New Haven] 657.
rare in Michigan, Mich. 819.
Spider, jumping, color markings, Ark. 387.
Spider mite, *see* Red spider.
Spinach—
culture and varieties, Tex. 45.
iodine in, 567; Okla. 131.
leaf miner, life history and control, 53.
lime test as control for damping off, Miss. 340.
magnesium requirements, Va.Truck, 779.
varieties for spring and fall, N.Y.State 201.
vitamin C in, N.Y.State 728.
wilt, role of *Verticillium* in, 494.
Spintherus, feeding habits and condition of ovarian follicles, correlation, 386.
Spirochaeta—
anserina of geese, 849.
gallinarum of fowls, 849.
Spirochetosis of fowls, 849.
Splenectomy, effect on anaplasmosis of sheep, 543.
Sporotrichum—
sp., isolation from black knots, 68.
spp., notes, 505.
Spotted fever group of diseases, criteria for accurate classification, 693.
Spray—
fungicides for potatoes, comparison, Me. 330.
injury, N.J. 638.
injury and practices to avoid it, 355.
injury to growing plants, fog chamber for determining, 511.
injury to peach and apple, relation to zinc sulfate, 494.
injury to rose leaves, 658.
management studies, N.H. 483.
materials, Ind. 778.
materials, need for more careful supervision, N.Y.State 141.
nozzle equipment, design for low-growing crops and herbicides, 409.
program, choosing, 810.
residue, arsenical, removal from fruit, 808; Wash. 45.
residue, effect of spray schedules and washing treatments, Ind. 778, 789.
residue information for orchardist and fruit packer, Oreg. 202.
residue problem, Conn.[New Haven] 657; Mass. 512; Ohio 202.

Spray—Continued.
residue problem, hazard from sea foods and drinking waters compared with, 340.
residue removal—
from apples, 346; Ind. 778; Va. 488.
from fruits, Conn.[New Haven] 374.
methods, 375.
new method, continued efficiency, Wis. 513.
new washing method, N J. 627.
notes, Ind. 778.
residue situation and new experiments, 808.
schedules for fruits, Ohio 201.
schedules for Illinois, 648.
Sprayers, stationary v. portable, Ind. 778.
Spraying—
data, Ohio 202.
of stone fruits, proper timing, 650.
stationary and portable, comparative costs, Ind. 778.
Sprays—*see also* Fungicides, Insecticides, *and specific forms.*
arsenical, effect of fatty acids on, Wash. 79.
copper, *see* Copper.
damage from, 807.
deposit, factors concerned in, 224.
home preparation and compatibility of materials, Ohio 201.
insecticide, spreading capacity, 807.
oil, *see* Oil sprays.
quantity regulation, device for, U.S.D.A. 76.
summer oil, new developments in, 814.
tar-oil and lubricating-oil, relation to rosy aphid control, 665.
timing, Ind. 806.
Spring, beginning, determination, 163.
Spruce
beetle, eastern, larval instars, 806.
black bark beetle, studies, 657.
damage from red squirrel, 786.
gall aphid, control, Conn.[New Haven] 374.
gall aphid, hibernating female, relation to survival of spring generation, Conn.[New Haven] 657.
nest worms, notes, 656.
sawfly, European—
in Connecticut, Conn.[New Haven] 374, 657.
outbreak in 1935 in Quebec, 387.
studies, U.S.D.A. 655.
Spumula—
new genus of rusts, 209.
quadrifida n.g. and sp., description, 209.
Spurge, leafy—
annual spread and control, Iowa 85.
growth, reproduction, and control, N.Dak. 475.
studies, Iowa 777.
Squabs, management on small farms, U.S.D.A. 86.
Squash—
and pumpkin hybrids, studies, N.Y.State 608.
bug in Connecticut, Conn.[New Haven] 657.
Buttercup, vitamin G in, N.Dak. 564.
plants, exudation in, 604.
plants grown by sheet-culture technic, effect of variation in rate of water flow, 456.
tender leaves and tops, vitamin B_1 in, 571.
vine borer, studies, Mass. 512; Wis. 513.
Squashes—
breeding, Conn.[New Haven] 339.
shrivelling, 628.
use for sirup, N.Dak. 504.
vitamin A in, 571.
winter, decay in storage, causes and control, Mass. 496.
Squirrel, red, damage to pine and spruce plantations, 786.
Staining with safranine and fast green FCF, 464.
Stallion—
semen, preservation, 326.
shows, Indiana Spring, 528.
Standards of living—
in Connecticut farm houses, factors affecting, [Conn.]Storrs 286.
in rural Montana, Mont. 734.
needed for rural resettlement, 714.
rural, in Tennessee, regional comparison, 714.
Staphylococci—
from animals, toxin production, 693.
inoculated eggs, hatchability, 260.
Staphylococcus infections in birds, 850.
Starch—
and starch products, alkali-labile value, 159.
determination, 159.
determination, improved technic, 303.
determination in fruits, 878.
hydrolysis and deuterium, 295.
of wheat, diastatic activity, 739.
reserves in woody plants, seasonal changes, 24.
Starling, rose-colored, in middle Asia, 75.
Statice, German, leaf spot, Tex. 57.
Stearine of cod-liver oil byproducts, antirachitic value, Nebr. 239.
Steel beams, types, fire resistance capacity of, 854.
Steel, zinc and cadmium coatings, corrosion-protective value, 115.
Steers—*see also* Cattle, beef.
beef, fattening on native feeds, Hawaii 529.
fattening, Nebr. 239.
fattening, beet pulp for, Wyo. 89.
fattening, mineral supplements for, Colo. 90.
fattening on locally produced feed mixtures, Hawaii 388.

Steers—Continued.
fattening, rations for, Tex. 88.
fattening, value of dicalcium phosphate in ration, Tenn. 820.
feeding experiments, Idaho 676; N.Dak. 529; Tex. 88.
finishing, Mich. 676.
finished on grass, amount of grain for, Tenn. 820.
marketing by truck and rail, factors affecting, Colo. 531.
yearling, corn-on-cob meal v. shelled corn for, Ohio 388.
Stephanoderes hampei—
notes, 808.
parasite, biology, 818.
Stephanurus dentatus, early developmental stages, U.S.D.A. 107.
Stereum durisculum, first report for North America, 790.
Sterility—
in cattle, causes, 194.
in cows, role of Trichomonas in, 543.
in cows, treatment, Mich. 257.
phenomena of irradiated mice, 470.
Sterols—
electrophoresis of, Minn. 582.
in avocados, Hawaii 415.
separation from vitamin D-containing materials, 11.
Stichorchis giganteus, adaptation to domestic pig, redescription, 848.
Stilbum cinnabarinum on fig in Louisiana, 788.
Stilesia vittata in ovines in India, 104.
Stinkbug, southern green, notes, Fla. 658.
Stirrer for solvent extraction, 6.
Stock, *see* Livestock.
Stock foods, *see* Feeding stuffs.
Stocks—
bud differentiation and flowering, temperature as factor in, 351.
damping-off of seedlings due to *Rhizoctonia solani*, 369.
Stockyards fever, *see* Septicemia, hemorrhagic.
Stomach—
human, emptying time, variations in, 568.
of ruminants, passage of fluids through, 390.
preparations, improvement of method, 427.
worms in lambs, control, 400.
worms in sheep and goats, Tex. 103.
Stomata—
and transpiration of oaks, 183.
behavior, effect of nutrient deficiencies, 456.
Stover, analyses and digestibile nutrients, U.S.D.A. 821.
Stoves, gas types, performance of surface burners and ovens, Nebr. 286.
Straw itch mite, parasite of *Tribolium*, U.S.D.A. 524.
Straw mulch for black raspberries, Ohio 340.
Strawberries—
breeding, Conn[New Haven] 339; Me. 340; N.J. 627; Tenn. 779; Tex. 45; Wash. 46.
culture, Ill. 630; Tex. 45.
damage from winter injury and dwarf, U.S.D.A. 636.
effect of nitrogen fertilizers, 630.
effect of soil reaction, N.J. 627.
fertilizer experiments, Iowa 44.
fertilizers for, N.H. 483.
Hawaiian, composition, nutritive value, and use, Hawaii 879.
in France, injuries from *Cnephasia virgaureana*, 374.
marketing, Ind. 778.
root injury, mulches for prevention, Wis. 483.
varieties, Iowa 44; Me. 340; N.H. 483; Tex. 45.
variety tests, Mont. 626; Tenn. 779.
Strawberry—
anthracnose, studies, 788.
blossom blight and pollination, effect of thrips on, 663.
bud rot due to *Rhizoctonia*, 788.
chlorosis, effect of soil application of sulfur, Tex. 57.
crinkle and yellows, simultaneous infections, U.S.D.A. 789.
degeneration, survey of research on, 222.
diseases, important in Florida, Fla. 636.
diseases in western New York, 365.
diseases, notes, 799.
Furasium root rot, 207.
gray mold, control, Conn.[New Haven] 356.
insects, problems of, 808.
leaf spot, effect of soil application of sulfur, Tex. 57.
Phytophthora disease, 801.
plants, warm water treatment, 807.
root rot due to *Diplodia*, 788.
root weevil control, Oreg. 525.
root weevils in Oregon, Oreg. 232.
rootworm, control, N.J. 658.
seedlings, root infection by soil microorganisms, microscopical study, 355.
seedlings, technic of handling, 627.
seeds, germination, 627.
sirup, making, Tenn. 879.
soils, fertilizer and soil reaction, 472.
tarsonemid mite, notes, 807.
weevil, damage, Conn.[New Haven] 657.
wilt or crown rot, notes, Fla. 637.
wilt, studies, 788.
yellows, control, Mont. 626.
Stream—
bank planting, Ohio 53.
run-off and tree growth, relation, Nev. 205.
Streams, pollution by raw sewage, Mass. 549.

Streptococci—
beta hemolytic, from milk, fibrinolytic activity, 841.
from human gastro-intestinal ulcerations and from bovine mastitis, comparison, 254.
hemolytic, classification, methods, 540.
hemolytic, from tonsils of domestic animals, 841.
hemolytic, in pasteurized milk, N.H. 535.
inoculated eggs, hatchability, 260.
resistance to pasteurization, 254.
Streptococcic infection of udder, effect on milk, 99.
Streptococcus—
citrovorus, products formed from citric acid and from lactic acid by, Iowa 97.
lactis, habitat, 688.
lactis, use in butter cultures, Iowa 97.
paracitrovorus, products formed from citric acid and from lactic acid by, Iowa 97.
Stripe rust in Canada, 500.
Strongyle larvae of horses, vertical migration in soils of different types, 545.
Strongyloides—
papillosus, notes, 401.
ransomi, early developmental stages, U.S.D.A. 107.
Struck, studies, 253.
Structural theory and design, treatise, 113.
Stumpage and log prices for 1934, U.S.D.A. 206.
Stylops melittae as bee enemy, 385.
Subsoils, unproductiveness, Mich. 592.
Sucrose—
determination in fruits, 878.
fat formation from, 422.
in leaf blades of sugarcane and other plants, fluctuations, Hawii.Sugar Planters' 26.
water solutions saturated to, solubility-freezing point relations, 252.
Sudan grass—
and Russian thistles as roughages for baby beef production, S.Dak. 677.
composition, N.Dak. 475.
culture experiments, Tex. 38.
grazing v. Sudan grass grazing and cottonseed cake for cattle, Tex. 88.
green, v. green alfalfa, feeding value, Hawaii 395.
green, v. green Napier grass or green alfalfa as soiling crops for dairy cows, Hawaii 395.
pasture for pigs, Nebr. 239; [Okla.] Panhandle 241.
pastures, tests for dairy cattle, S.Dak. 684.
search for line low in prussic acid, Wis. 475.
toxicity, 255.
v. alfalfa pasture for dairy cow, Ohio 395.
Sugar—*see also* Sugars.
bacteria in, Idaho 720.
corn, utilization in production of lactic acid, Iowa 4.
in blood, *see* Blood sugar.
Sugar beet—*see also* Beet.
byproducts for fattening lambs, Wyo. 822.
Cercospora leaf spot resistant strains, breeding, Iowa 55.
crop of Iowa, important characteristics, Iowa 119.
curly top, breeding for resistance, N. Mex. 36.
curly top resistant varieties, new, U.S. D.A. 478.
diseases, Iowa 55.
diseases in Louisiana, La. 502.
diseases of seedlings, control, 501.
diseases, virus, Mont. 638.
insects in Ontario, 662.
leaf spot epidemiology, relation to infested soil, 495.
leaf spot, host response and control, Iowa 55.
machinery, Colo. 260.
nematode, host plants, U.S.D.A. 55.
rot due to *Phytophthora drechsleri*, 217.
seed, annual production, N.Mex. 36.
tops, effect on milk flavor, Mich. 683.
yellowing disease, cause, 502.
yellows mosaic, studies, 794.
Sugar beets—
breeding, Idaho 616.
Cassida beetles affecting, 374.
copper deficiency in, 502.
cost of production and marketing, Mich. 866.
culture experiments, Iowa 35.
damage by flat wireworm in Canada, 817.
effect of carbon dioxide on pH and nitrogen fractions, 4.
effect of phosphatic fertilizers, Mont. 453.
effect of preceding crops and seedbed preparation, Mich. 616.
fertilizer experiments, Wyo. 39.
manure tests for, Nebr. 195.
response to phosphorus, Mont. 616.
rotation experiments, U.S.D.A. 617.
sucrose or purity coefficient, errors of routine analysis for, 442.
varieties, response to day length and temperature, 755.
variety tests, Idaho 616; N.Mex. 36; Wash. 38.
Sugarcane—
artificially inducing bud variations in, Fla. 615.
borer, effect of cold water treatment of cane, 519.
borer, prevalence and control in south Florida, Fla. 658.
breeding, Fla. 615.
composition, relation to growth and maturity, Fla. 615.

Sugarcane—Continued.
cut, for range cattle, Fla. 675.
diseases, Fla. 637.
diseases in British Guiana, 357.
diseases in Hawaii, relation to soil fertility and plant nutrition, 795.
diseases in Puerto Rico, U.S.D.A. 636.
effect of frost of January 1934 in India, 12.
effect of nitrogen nutrition, 623.
effect of zinc sulfate, Fla. 210.
ensilability, Fla. 683.
fertilization test, balanced block arrangement of treatments, Hawaii. Sugar Planters' 766.
growth, dominating effect of climate, Hawaii.Sugar Planters' 774.
insects affecting, 806.
insects in Queensland, 808.
internal water economy, Hawaii.Sugar Planters' 602.
juice, composition from cane injured by borer or red rot disease, 150.
leafhopper in Hawaii, biological control, Hawaii.Sugar Planters' 664.
mosaic, transmission by rusty plum aphid, 811.
mosaic virus, physical properties, 796.
moth borer, 806.
moth borer attacking in Guatemala, Hawaii.Sugar Planters' 82.
phosphorus requirements on Everglades soils, Fla. 591.
plants, effect of varying quantities of potassium, 437.
production, use of manure and cattle feed production in rotations for, 529.
roots, segregated, absorption of essential elements by, Hawaii.Sugar Planters' 795.
sirup and sugarcane-citrus sirup blends, Fla. 717.
sugars in leaf blades, fluctuations, Hawaii.Sugar Planters' 26.
surplus, stack silo experiments with, Fla. 616.
table sirups from, manufacture, P.R. 745.
top borer in Punjab, 70.
varieties, disease resistance tests and seedling selections, 645.
variety tests, La. 474, 774; Miss. 331; U.S.D.A. 622.
weevil, New Guinea, notes, 808.
yield and composition, effect of nitrogen fertilization, Hawaii.Sugar Planters' 623.
Sugars—*see also* Glucose, Lactose, Sucrose, *etc.*
in sugarcane, effect of potassium, 437.
rates of absorption and glycogenesis from, 422.
soft, mineral content, Miss. 879.
tarsal chemoreceptor response of housefly to, 382.
Suint, distribution over fleece of Merino sheep, 240.
Sulfate of ammonia, *see* Ammonium sulfate.
Sulfates, conservation, Tenn. 747.
Sulfur—
and phosphorus in plants grown on same soil, comparison, 317.
as fungicide, Tex. 57.
as insecticide, Tex. 78.
dioxide fumigation in greenhouses, effect on zinc-galvanized pipes and wires, 791.
effect on potato scab, N.H. 474.
effect on toxicity to rats of wheat from selenized soil, 842.
for bacterial wilt control, 494.
forms for apple scab control, Mich. 220.
fungicidal properties, 496.
in organic compounds, determination, 301.
in proteins, unrecognized forms, 294.
in tobacco, S.C. 37.
metabolism, absorption and excretion of flowers of sulfur, 820.
oxidation in Arizona soils, effect, Ariz. 22.
requirements of *Azotobacter chroococcum*, 174.
selenium in, determination, 441.
spraying of prunes, effect on corrosion of cans, 585.
waters, effect on seed germination and plant growth, 317.
Sumac fodder and silage, feeding value, Tex. 87.
Sun, effect on wildlife population cycles, Wis. 509.
Sun spots, effect on human affairs, 746.
Sunflower silage, *see* Silage.
Sunflowers—
elongation and expansion in, studies, 184.
pyralid moth affecting in Manitoba, 815.
susceptibility to *Rhizoctonia solani*, 61.
tissue function and organic solute movement in, 758.
Sunlight—*see also* Light.
effect on milk, S.Dak. 684.
Sunn-hemp wilt, effect of temperature and maturity, 364.
Superphosphate—
ammoniated, availability, R.I. 752.
effect of limestone and dolomite, Tenn. 747.
efficiency for cotton, 473.
v. rock phosphate in southern Idaho, Idaho 592.
Superphosphates—
composition and properties, 155.
selenium in, 176.
Surinam-cherry, composition, nutritive value, and use, Hawaii 879.
Surra studies, 254.
Sweat, bloody, of horse, pathogenesis, 103.
Swede brown heart, control, 364.

borax requirements, Me. 340.
table stock, culture, Mich. 780.
Sweet corn—*see also* Corn.
bacterial wilt resistant strains and varieties, N.J. 638.
breeding, Conn.[New Haven] 339; Fla. 615; Hawaii 330; Iowa 44; Me. 340; P.R. 778.
carbohydrate fractions, Fla. 615.
Golden Bantam, inbred lines, combining ability, 464.
hybrids, new early, tests, Ohio 331.
index of quality, alcohol-insoluble residue as, 200.
seed treatment, Wyo. 58.
Stewart's disease, monograph, Mich. 642.
transportation to New York City, P.R. 778.
variety tests, Idaho 616; N.J. 627; N.Y.State 198; S.C. 45; Tenn. 779; Tex. 38.
Sweet peas—
anatomy, metabolism, and bud abscission, effect of nutrient concentration, 759.
fasciation, bacteria in relation to, 496.
fasciation in, Ohio 357.
metabolism and bud abscission, N.J. 627.
sand culture, N.J. 627.
Sweetclover—
alfalfa, and red clover, relative value as soil-building crops, Iowa 14.
and alfalfa as companion crops, competition, Wash. 38.
as green manure for beans, Mich. 616.
biennial, eradication, Iowa 35.
biennial white, winter hardiness in, Iowa 35.
breeding, Idaho 616; Wash. 38.
coumarin-free, breeding, 478.
culture experiments, Tex. 38.
disease of cattle, N.Dak. 537.
effect of phosphatic fertilizers, Mont. 453.
flowers, emasculating, field aspirator for, 775.
insects as pollination agents of, S.Dak 659.
pastures, tests for dairy cattle, S.Dak. 684.
residual effects, [N.Y.]Cornell 450.
response to phosphorus, Mont. 616.
seed samples, analysis, time required for, 625.
variety tests, Fla. 615; Iowa 35; N.Dak. 474; Tex. 38; Wash. 38.
Sweetpotato—
black rot, treatment, 787.
growers, practices in Jones County, Mississippi, 474.
root rots, N.Mex. 56.
scurf, control, N.J. 638.
seed stock, disease-free, propagation, Iowa 55.
stem rot, control, 788.
Sweetpotatoes—
cost of production, N.J. 711; U.S.D.A. 711.
culture experiments, Ga.Coastal Plain 104; N.Mex. 36.
feeding value for pigs, Fla. 675.
fertilizer experiments, Conn.[New Haven] 330; Ga.Coastal Plain 104.
for fattening swine, Hawaii 520.
grazing trial and effect on yields, La. 474.
iodine in, Okla. 131.
Nancy Hall, sprout production, effect of seed size, 474.
propagation, effect of temperature and character of bedded roots, 473.
raw, feeding value for pigs, Hawaii 388.
regular slip pulling v. ordinary slip pulling in, 474.
slip seeding for disease control, Conn. [New Haven] 356.
storage, Ind. 851.
storage quality, Iowa 35.
tender leaves and tops, vitamin B_1 in, 571.
varieties and cultural practices, Miss. 775.
variety tests, Hawaii 330; La. 474; Tenn. 767.
vitamin A in, 571.
Swellhead in sheep and goats, Tex. 103.
Swimming-pool waters, quality, bacterial studies, Mich. 735.
Swine—*see also* Pigs *and* Sows.
blood chemistry, 241.
breeding studies, Iowa 86.
disease, anaplasmosis-like, in Formosan swine, 544.
diseases, parasitic, and parasites in Puerto Rico, P.R. 543.
diseases, spread, community sales as factor, 101.
dysentery in Iowa, 101.
erysipelas—
agglutination test, preparation and use of antigen for, 848.
bacillus in fishes, 103.
infection in turkeys, 260; N.J. 691.
serological diagnosis, 101.
vaccine, living, studies, 104.
foot development, bone inequalities in, Idaho 676.
influenza virus, immunization experiments, 847.
intestinal distomatosis, new fluke as cause, 401.
inverted nipples, inheritance, Idaho 676.
organs, effect of gonad stimulants, 325.
polydactyly in, 32.
pox in Chosen, 103.
pox, studies, 102.
pregnancy in, hormonal method for detection, 325.
Swiss chard, iodine in, Okla. 131.
Sylepta derogata in Punjab, 79.
Symptomatic anthrax, *see* Blackleg.

Syngamus spp. in nasal fossae of sheep in Brazil, 847.
Syntomaspis eurytomae n.sp., studies, 657.
Syntomosphyrum esurus, parasite of cotton leaf worm, 230.
Syphacia peromysci n sp, description, 804.
Tabanidae in Dutch East Indies and economic importance, 656.
Tabanus—
atratus, *see* Horsefly, black.
fusciocostatus, attempted transmission of anaplasmosis by, 840.
Tachinidae, biology, 79
Tachypterellus quadrigibbus, *see* Apple curculio.
Taeniothrips gladioli, *see* Gladiolus thrips
Taeniothrips inconsequens, *see* Pear thrips.
Takuwan, commercial, analyses, Hawaii 415.
Tamarind, composition, nutritive value, and use, Hawaii 879.
Tanaemyrmex compressus, economic status, 79.
Tankage—
effect on flavor in milk, S.Dak. 684.
efficient utilization by pigs in dry lot, Nebr. 239.
feeding value, Kans. 531.
need of large quantities for gilts, Wis. 530.
types, for pigs without pasture, Ohio 389.
v. cottonseed meal for dairy cows, N.Dak. 535.
Tanks, temperature stresses in, 266.
Tannin—
estimation of amino nitrogen in presence of, 584.
in plant cells, physiology, 316.
Tapeworm, European broad fish, notes, 709.
Tapeworms—
in crows, 851.
in poultry, ant as intermediate host for, 403.
in poultry, control and pathology of intestines of hosts, Mich. 259.
in sheep, 696; Wyo. 103.
infestation, Mich. 601.
Taphrina deformans, life history and parasitism, 67, 68.
Tar distillate emulsions for apple aphid control, 375.
Tar oil and lubricating oil sprays, tests, 665.
Tariff barriers, Cuban, Iowa 119.
Tarnished plant bug, control, Ind. 806; Mich. 658.
Tarsonemus—
fragariae, notes, 807.
pallidus, *see* Cyclamen mite.
Tartaric acid in food products, 5.
Tax delinquency—
and mortgage foreclosures of Montana, Mont. 860.
farm, marked increase from 1928 to 1932, Okla. 412.
in Maryland, Md. 122.
on farm real estate, S.C. 120.
Tax delinquency—Continued.
on rural real estate in New Mexico, N.Mex. 272.
rural, Mass. 554; N H. 556
Tax levies for school support in a low property value county, Wis 555.
Tax sales, redemption, etc, Mass. 554.
Taxation—
farm, R I. 863.
rural, and public revenue in Ohio, Ohio 272.
trends, relation to agriculture, 272.
Taxes—
farm real estate, changes in for period 1913–32, Tex. 120.
State income and classified property, constitutionality, Colo. 123.
Taxus die-back due to *Phomopsis* sp., N J. 638.
Tea—
bush diseases, 369.
diseases, 208.
red rust, control, 223.
Teeth—
decay, relation to aciduric bacteria and food elements, 733.
defective, relation to diet, 890.
development, relation to fluorine, 733.
judging age of sheep by, Mont. 678.
mottled enamel in rural districts of Arizona, relation to fluorine in water supply, 731; Ariz. 732.
mottled, experimental and histologic analysis, 731.
temporary, mottled enamel on, 731.
Temperature—*see also* Climate *and* Soil temperature.
distribution, blood flow, and heat storage in body, 279.
in a growth of conifers, effect of clouds and wind, 12.
of New England, geographical study, 162.
soil, of greenhouse crops, effect, 349.
terrestrial, dependence on variations of sun's radiation, 443.
variation, effect on precipitation and weather in Denmark, 591.
vital optimum, relation to speed of development in insects, 656.
warm waves, origin, 591.
Tenebrio molitor, *see* Meal worm, yellow.
Tenebrioides mauritanicus, *see* Cadelle.
Tengkawang fruits, insect damage to, 376.
Tennessee Station, report, 893.
Tennessee University, notes, 895.
Tensiometers for measuring capillary tension of soil water, 594.
Tent caterpillar—
eastern, abundance, Conn.[New Haven] 657.
eastern, revision of bulletin, Conn.[New Haven] 82.
forest, notes, Conn.[New Haven] 657.
Tenuipalpus irritans, effect of freeze of 1934, 663.
Termites, control, Mo. 77.

Termites, control in buildings, Conn.[New Haven] 376.
Termites, damage from, 227; Conn.[New Haven] 657.
Terraces, construction methods and costs, Iowa 111.
Terracing—
machine, new type, Iowa 111.
plow, use for soil conservation, 706.
studies, N.J. 702.
Testes of rams and bulls, development, Mass. 466, 612.
Testicular hormone, inability to masculinize plumage and eye-color of female blackbird, 329.
Testicularia cuperi, notes, Tex. 57.
Testing equipment, dimensions, affect Hubbard-Field stability values, U.S.D.A. 552.
Tetanus in tropics, immunization of horses against, 104.
Tetrachlorethane for eradication of root rot, tests, Tex. 57.
Tetrahydronaphthalene and ethylene dichloride-carbon tetrachloride as moth fumigants, comparison, 655.
Tetralopha robustella in Connecticut, Conn. [New Haven] 657.
Tetramorium caespitum, intermediate host for *Raillietina echinobothrida*, 403.
Tetranychus—
citri, effect of freeze of 1934, 663.
telarius, *see* Red spider.
Tetrastichus brevistigma n.sp., description, 818.
Texas Station, report, 141.
Textile chemistry, studies in, Iowa 139.
Thallium sulfate, toxicity for cattle, Colo. 252.
Thallous chloride, activity of coefficient, effect of amino acids, 294.
Theelin—
effect on atrophic uteri of castrated rats, 34.
effect on development of mammary gland, Mo. 35.
injection, effect, 34.
preparation from human and mare urine, 765.
prolonged administration to rats, effect on reproduction, 34.
theelol, and oestrogenic substance from male urine and bull testis, comparison, 34.
Theelol—
effect on development of mammary gland, Mo. 35.
prolonged administration to rats, effect on reproduction, 34.
theelin, and oestrogenic substance from male urine and bull testis, comparison, 34.
Theileria spp., effect of splenectomy, 543.
Thermobia domestica, *see* Firebrat.
Thermometers, round-form distance, field support for, U.S.D.A. 76.
Thielaviopsis paradoxa on coconuts, 208.
Thiocyanates, aliphatic, insecticidal activity, 662.
Thiodiphenylamine as food poison for firebrat, 525.
Thiol compounds, determination, 0.
Thiourea, effect on apical dominance of tree branch, 461.
Thistle—
Canada, control, Wyo. 30.
Russian, and Sudan grass as roughages for baby beef production, S.Dak. 677.
Russian, as forage crop, Wyo. 89.
Russian, hay, digestibility and feeding value, 834.
Thiuram sulfides, repellents to leaf-feeding insects, 512.
Thorne, C. E., contribution to agricultural research, Ohio 893.
Thornheaded worm of swine, 543.
Thresher adapted to individual heads of sorghum, 409, 553.
Thricolepis inornata on strawberries, Oreg. 232.
Thridopteryx ephemeraeformis, control, N.J. 380.
Thrips—
attacking man, 810.
cause of chili leaf curl, 70.
Thrips imaginis—
immature stages, rate of development, effect of temperature, 377.
in South Australia, life history and control, 810.
life history and control, 378.
Thrips tabaci, *see* Onion thrips.
Thymus, effect on growth relation to phosphorus, calcium, and lipin metabolism, Fla. 717.
Thyreoidin, superfluous, mechanism of sterilizing effect on pregnancy in rats, 469.
Thyrididae, Indian, life histories, 815.
Thyridopteryx ephemeraeformis, *see* Bagworm(s).
Thyroglobulin, normal and goitrous human, thyroxine and iodine in, 148.
Thyroid—
colloids, secretion and resorption, histological processes in, 469.
gland and female sexual system, mutual relation, 469.
gland and vitamin B deficiency, 469.
gland of rat, effects of deficiency of iodine and vitamin A on, 420.
material, thyroxine determination in, 297.
weight of newly hatched chicks, relation to sex, 242.
Thyroidectomy of pregnant rabbits, effect on duration of gestation period, 612.
Thyroidin and thyroxin, comparative activity, 326.
Thyroxin—
and thyroidin, comparative activity, 326.
in thyroid substance, determination, 297.
toxicity, protective action of vitamin B_1, 425.

Thysanoptera of California, list, 377.
Tibicen pruinosa, nerve lesions after paralysis by killer wasp, 379.
Tibicina septendecim, *see* Cicada, periodical.
Tick—
fever, Rhodesian, *see* African coast fever.
Pacific coast, vector of anaplasmosis in California, 254.
winter, vector of anaplasmosis in California, 254.
Tick-borne fever of sheep, 397.
Ticks—
in Argentina, 85.
new, collected from rodents in Wyoming and Washington, 819.
of Madagascar and diseases transmitted by them, 540.
transmitting relapsing fever, host relations, 819.
Tillage—
implements, cutting edges, studies, 407.
machinery, use in soil-drifting areas, 116.
Tilletia tritici—*see also host plants.*
physiologic forms, differentiating characteristics, 211.
Timber—*see also* Lumber *and* Wood.
Australian, strength of notched beams, tests, 704.
for basket stock, marketing, Ind. 787.
growing and logging practice in ponderosa pine, U.S.D.A. 786.
longitudinal variation during seasoning, 261.
parasitic staining in Italy, 372.
preservation against *Lyctus* powder post borer, 384.
resources and marketing practices in Dubois County, Ind. 784.
seasoning stacks, flow of air through, measurement, 704.
Timbers—
structural, strength tests, 262.
testing at Forest Products Research Laboratory, 262.
Timothy—
and alfalfa mixtures v. nitrogen-treated timothy, Ohio 331.
breeding, N.J. 616.
breeding for rust resistance, importance, 217.
hay, feeding experiments with lambs, Ohio 389.
meadows, improvement by fertilization, Me. 330.
nitrogen fertilization at heading for increasing protein in, N.J. 616.
open-pollinated, selection, 623.
response to soil reaction, R.I. 767.
seed production, U.S.D.A. 338.
sod treated with calcium cyanamide, yield for ensiling, N.J. 684.
sowing in thin alfalfa stands, Ohio 623.
susceptibility to *Rhizoctonia solani*, 61.
variety tests, Alaska Col. 766.
Tineola biselliella, *see* Clothes moth, webbing.
Tip borer on mango inflorescence in Philippines, 375.
Tissue grafts in rats, organismal differentials by means of, 762.
Tissues, magnesium determination in, closed titration flask for, 301.
Titanium, determination of manganese in presence of, 430.
Titanous chloride, effect on chlorophyll formation in corn, 25.
Tithonia rotundifolia, mosaic disease of, 494.
Toad, giant, introduction into Australia, 808.
Tobacco—
black root rot resistant strains, Mass. 496.
cigar-wrapper, resistant to blackshank, Fla. 637.
culture experiments, Ga.Coastal Plain 194.
damage by flat wireworm in Canada, 817.
disease resistance in, 494.
diseases, 208; Conn.[New Haven] 356; Ga.Coastal Plain 218; Ky. 796.
diseases, field and laboratory studies, Fla. 637.
diseases in North Carolina, U.S.D.A. 207.
diseases in western Kentucky, U.S.D.A. 636.
downy mildew—
control, Ga.Coastal Plain 218.
effect of nutrients on susceptibility to, 494.
in Kentucky, U.S.D.A. 636.
in North Carolina, U.S.D.A. 356.
notes, 788, 796; S.C. 56.
promising fungicides for, 494.
experiment, Kansas, 36.
experiments, Mass. 474.
fertilizer experiments, Ga.Coastal Plain 194; S.C. 37.
flea beetle, control, U.S.D.A. 655.
flea beetle under cage conditions, 224.
Florida cigar-wrapper, germination of seeds, 474.
frenching, 218.
growers, seed and soil testing service for, Conn.[New Haven] 330.
hybrid for virus studies, 645.
insects, control, U.S.D.A. 655.
insects, injuries and control, Conn.[New Haven] 80.
insects, notes, Tenn. 806.
leaf miner in north Queensland, 808.
leaves, healthy and mosaic infected, metabolism, 456.
Maryland, production, marketing, and consumption, Md. 125.
mosaic and ring spot, effects of aldehydes, 456.
mosaic, burning and nonburning strains, Ky. 797.
mosaic, evidence of virus mutation, 66.

Tobacco—Continued.
mosaic from plants one to fifty-two years old, Ky. 798.
mosaic, localization and resistance to, Ky. 797.
mosaic, mild, on plants, susceptibility to other strains, Ky. 796.
mosaic, mild strains, effect on susceptibility to other strains, 494.
mosaic, strains causing mosaic-burning, 788.
mosaic virus—
behavior in soil, 218.
formation of local lesions by, 798.
overwintering in soil, Wis. 497.
possible chemical nature, 645.
protein, crystalline, isolation from diseased tomato plants, 798.
protein, crystalline, preparation, 495.
purification, Mo. 502.
strains, method for describing, 496.
yellow strains, origin, 796.
mosaic viruses, localization, effect of necrotic lesions, 788.
moth, life history and control in warehouses, 660.
outlook charts, U.S.D.A. 120.
plant bed diseases in Georgia, U.S.D.A. 496.
prices, S.C. 120.
ring spot, protection of one strain against a more injurious strain, Ky. 798.
root rot resistance, inheritance, 646.
rotations, Ohio 331.
seed, germination studies, Conn.[New Haven] 330.
seed, storage and germination studies, Fla. 616.
seedbed diseases in Maryland and Florida, U.S.D.A. 635.
seedbed soil disinfection 788.
seedbed survey in Wisconsin, U.S.D.A. 636.
seedlings, root infection by soil microorganisms, microscopical study, 355.
shade, better strain of, Conn.[New Haven] 330.
stem borer in north Queensland, 808.
stored during fumigation experiments, apparatus for placing test lots of insects within, U.S.D.A. 655.
streak, a virus disease, 646.
streak disease, cause, Wis. 497.
thrips, studies, S.C. 78.
toxicity of aluminum salts, 66.
under AAA, 413.
variety tests, Tenn. 767.
wildfire, relation to water soaking of leaves, 219.
wilt due to *Phytomonas solanacearum*, 207.
worms, effect of Alorco, Tenn. 84.
wrapper, green spot disease, 207.
Tolylpyrrolidine, dextro- and levo-alpha-para, toxicity to *Aphis rumicis*, 224.
Tomato—
bacterial canker, N.J. 638.
bacterial wilt, control, 404.
black spot, control, Fla. 637.
crosses with *Lycopersicum peruvianum*, 191.
curly top in Utah, U.S.D.A. 789.
damping-off, seed treatment, Tex. 57.
diseases—
greenhouse, control, Mass. 496.
in British Guiana, 357.
in Mississippi, U.S.D.A. 789.
in Utah, U.S.D.A. 207.
new virus, 66, 364.
studies, Ind. 789; Tex. 57.
survey distribution, Wis. 497.
virus, Mont. 638.
fruitworm, studies, S.C. 78.
Fusarium wilt resistant strains, Tex. 57.
juice, home canning to preserve vitamin C content, Wis. 564.
late blight, notes, Conn.[New Haven] 356.
leaf and fruit spot, control, Tex. 57.
leaf mold, nature and control, 787.
leaf mold resistance, 646.
leaf mold resistant variety, development, 493; Ohio 357.
leaf mottle, control, Tex. 57.
leaf spot resistant varieties, breeding and selection, Tenn. 789.
leaves, spray injury, R.I. 789.
mite, 819.
nailhead spot, studies, 787.
pin worm, status in Pennsylvania, 519.
plant, composition, effect of ammonium and nitrate nitrogen, 342, 602.
plant irradiation, change in mineral composition, 455.
plants, mosaicked, crystalline protein isolated from, 798.
plants, stem growth, effect of ethylene, 456.
psyllid, control, Colo. 224.
seed and seedling decays, comparison of seed treatments, 494.
seed treatment with copper dusts, N.J. 638.
seedbed, damping-off in, control, Tex. 57.
seedling diseases, control, 788.
seedlings, damping-off, Mo. 56.
seeds, storage, 46.
spotted wilt, unusual occurrence in Utah, U.S.D.A. 496.
suck fly, control, Tex. 78.
wilt, control, Fla. 636.
wilt-resistant varieties, new for field and greenhouse, 647; Ill. 201.
Tomatoes—
Arkansas Marglobe, constituents, 710.
as fall crop in greenhouse, Ohio 485.
breeding, Conn.[New Haven] 339; N.J. 627; Tex. 45; Wash. 46.

Tomatoes—Continued.
canned, quality, factors affecting, 719.
carotenoid formation in, effect of light, [N.Y.]Cornell 629.
cost of production in northern Indiana, Ind. 863.
culture, Ill. 343; Mont. 626; Tex. 45.
culture, diseases, and pests, Ga. 48.
culture experiments, Ga.Coastal Plain 197.
effect of drought on nutrient levels in, 47.
fertilizer experiments, Fla. 626; Ga. Coastal Plain 197; S.C. 45.
Glovel, description, U.S.D.A. 201.
greenhouse, affected by blotchy ripening, histological study of tissues, 219.
greenhouse, growth and yield, effect of soil moisture, Ohio 340.
greenhouse, in soils of different reactions, effect of nitrate and ammonium nitrogen, Ohio 340.
greenhouse, sterility, relation to salt concentration in nutrient solution, N.J. 627.
growth and composition, effect of concentration of nutrient solution, N.J. 601.
high and low carbohydrate, gall production, 495.
in eastern Texas, dusting and spraying, Tex. 57.
inheritance of fruit size and shape, Iowa 44.
inherited characters in, 31.
iodine in, Okla. 131.
late, spray tests with, R.I. 789.
new hybrid, Nystate, N.Y.State 47.
pollen cells in, effect of carbohydrate and of nitrogen deficiency, 464.
pollination and life history studies, [N.Y.]Cornell 47.
puffing in, control, Tex. 45.
quality and yield, effect of fertilizers, Md. 201.
quality, factors affecting, Ind. 778.
seed production, Ind. 778.
severe injury from two rare insects, Tex. 78.
shrivelling, 628.
spraying, Fla. 637.
spraying experiments, Ohio 357.
variations in fleshiness, effect of fertilization, 780.
varieties, Iowa 44; N.H. 483; Tex. 45.
varieties and cultural requirements, Hawaii 339.
varieties and culture, Me. 340.
variety tests, Fla. 626; Ga.Coastal Plain 197; N.J. 627; N.Mex. 45; N.Y.State 198; Ohio 340.
vitamin C in, N.Y.State 728.
Tortrix—
citrana, *see* Orange tortrix.
larvae, effects of various gas mixtures, 807.
postvittana, braconid parasite of, 386.
Torula lactis-condensi and *T. globosa* in sweetened condensed milk, 251.
Torula-like fungus, isolation from black knots, 68.
Toxemia in sheep, Mo. 102.
Towotrypana curvicauda, *see* Papaya fruitfly.
Tracheitis, infectious, [Conn.]Storrs 252.
Trachelus tabidus, notes, Ohio 374.
Tractor—
equipment, pneumatic, N.H. 549.
track efficiency, Iowa 111.
Tractors—
drive-wheel diameter, relation to tractive efficiency, Iowa 111.
farm, pneumatic tires for, Nebr. 260.
field machinery hitches for, S.Dak. 702.
low-pressure pneumatic tires for, Ind. 851; Mich. 701.
tire size, effect on drawbar pull and travel reduction, 406.
use, Iowa 111.
Trade
agreement, Canadian, and Michigan agriculture, Mich. 268.
agreements program and American agriculture, 269.
centers in Tennessee, Tenn. 716.
Trametes pini, studies, 509.
Transpiration—
and cooling of leaves, 603.
effect of light, 312.
from oaks and stomata, 183.
measurements, preparation of three-color strips for, 754.
measuring, new method, 459.
of plants, empirical formula for, 459.
stream, streamline flow and movement of solutes in, 183.
Transportation of Kentucky, 270.
Tranzschelia pruni-spinosae, types of teliospores in United States, 494.
Traps, electric, for codling moth control, Ind. 851.
Tree—
branch, apical dominance, effect of thiourea, 461.
cankers, fungi associated with, 507.
cankers, studies, 223.
diseases, development, relation to constitution and environment, 353.
diseases of Iowa, Iowa 55.
Trees—
colored zones associated with decay, 494.
coniferous, *see* Conifers.
evergreen, *see* Evergreen trees.
forest, in northwestern Pennsylvania, age-size relations, 784.
forest, insects affecting in South Africa, 376.
forest, species of continental United States, U.S.D.A. 205.
grown on prairie soils, root systems, 180.
growth, and stream run-off, relation, Nev. 205.

Trees—Continued.
hardwood, decay following fire in Mississippi Delta, U.S.D.A. 71.
hardwood, *Nectria* disease in New England, 802.
hardwood, root disease due to *Phytophthora cambivora*, U.S.D.A. 780.
leafy, resin content, effect of climatic conditions, 180.
new and noteworthy, in Texas and Mexico, 352.
propagation for possible erosion control value, Iowa 53.
shade, effect of oil, 514.
shade, insects affecting, 663.
shade, insects affecting in South Africa, 376.
shade, leaf diseases, 507.
shelterbelt, broadleaf and conifer species for, tests, Mont. 626.
shelterbelt experiments in North Dakota, U.S.D.A. 493.
shelterbelt planting in early forestry, Minn. 735.
shelterbelt, planting in Plains region, possibilities, U.S.D.A. 351.
species for planting under different conditions, Iowa 53.
windbreak plantings in Jasper County, Ind. 784.
windbreaking effects of different types of shelterbelts, 784.
winter-injured, frost ring formation, 313.
Trematodes—
antagonistic action of normal serum of vertebrates, 694.
invading *Lymnaea* snails as first intermediate hosts, 103, 104.
Tremella tuberoularia, first report for North America, 790.
Triaspis thoracicus, favorable hibernation important to, Idaho 658.
Tribolium—
castaneum, life history, U.S.D.A. 524.
confusum, *see* Flour beetle, confused.
genus, partial revision, key, U.S.D.A. 524.
Trichinae, development in abnormal environments, 255.
Trichinosis, laboratory diagnosis, 398.
Trichiotinus genus, biology and taxonomy, 383.
Trichoderma lignorum, penetration into sapwood of *Pinus taeda*, 508.
Trichogramma—
life history on eggs of bruchid beetles, 79.
minutum efficiency, relation to population density of its host, 655.
minutum, mass production, new equipment for obtaining host material, U.S.D.A. 85.
pretiosa, parasite of cranberry fruit worm, Mass. 512.
spp., prolificacy and size, host influence, 356.
Trichomonad flagellates from birds, n.spp. and n.v. descriptions, 260.
Trichomonas—
abortion in cattle, studies, 104.
foetus, action on central nervous system, 540.
foetus in cattle in Netherlands, 695.
foetus infection in sheep, 258.
relation to diseases of cattle, 543.
Trichothecium roseum, mutation in, 466.
Trichuris suis—
early developmental stages, U.S.D.A. 107.
notes, 400.
Tripsacum, *Euchlaena*, and corn, genetic and cytological relations, Tex. 38.
Trombicula autumnalis, seasonal occurrence on voles and mice, 388.
Trout, brook, calcium and phosphorus in body, relation to age, growth, and food, 882.
Truck crops—
fertilizer experiments, Fla. 626.
in southeastern Iowa, fertilizers for, Iowa 44.
outlook charts, U.S.D.A. 120.
Trucks, *see* Motor trucks.
True's history of agricultural experimentation and research, editorial, 737.
Trypan blue, toxicity, 538.
Trypanosoma—
equiperdum, effect of low body temperature in mammals, 541.
hippicum, transmission by vampire bat, 399.
lewisii, resistance of young rats to, development, 841.
Trypanosomes, variability in size and density of infection, 254.
Tryptophane, role in nutrition of fowls, N.J. 680.
Tubercle bacillaemia, 104.
Tubercle bacilli—
avian, distinct serological types, 105.
H_{37} strain and B.C.G., response of fetal guinea pigs to inoculation, 541.
in milk, 397.
survival on pastures, 252.
Tuberculin test, limitations, Wis. 538.
Tuberculina maxima on aecia of *Cronartium cerebrum*, 209.
Tuberculosis—
avian, studies, N.Dak. 537.
bovine, control in Jamaica, 538.
bovine pulmonary, in man, 541, 542.
control and eradication activities, necessity in modified accredited areas, 101.
eradication, progress in, 101, 399.
family, due to bovine tubercle bacilli, 541.
immunization with B.C.G. and diaplyte vaccine, 397.
in a crow, 851.
in herd of hogs fatal to all, 544.
in poultry, summary, Mo. 849.
progressive, in cattle due to avian tubercle bacilli, 397.

Tuberculosis—Continued.
pulmonary, in humans in Scotland, isolation of bovine type of bacilli, 542.
susceptibility in cattle, inheritance, 324.
uterine, in cows, 397.
Tubers, analyses and digestible nutrients, U.S.D.A. 821.
Tularemia—
epizootic, among susliks, 106.
transmission by bites of infected bedbugs, 811.
Tulip bulbs, production, N.Mex. 45.
Tulips, general information, U.S.D.A. 493.
Tumor formation, secondary, on herbaceous hosts, 61.
Tumors of—
domestic animals, comparative pathology, 396.
sheep, 400.
Tung root tips, chromosome number and morphology, 323.
Tung-oil trees—
adaptation trials, S.C. 45.
culture and fertilizer experiments, Miss. 340.
culture experiments, Tex. 45.
culture in Georgia, Ga. 492.
effect of zinc, Fla. 626.
propagation, planting, and fertilizer experiments, Fla. 626.
varieties, Fla. 626.
Tungseed meal, poisonous to livestock in Florida, Fla. 690.
Tungstate ions, action in water and sand culture experiments, 318.
Turf—
disease, pink patch, control, R.I. 789.
establishing and maintaining, N.J. 617.
freedom from weeds, comparison of composts, R.I. 767.
grasses on lawns, parks, and recreation fields, feeding, N.J. 619.
response to artificial watering, Ohio 331.
Turkey—
and chicken hybrids, experimental production, 611.
breeders, selection and management, 829.
disease, new, Idaho 690.
eggs, artificial incubation, temperature studies, N.Dak. 530.
eggs, hatchability, S.Dak. 677.
eggs, incubation, Ky. 534; Nebr. 239.
poults, calcium supplements in ration, N.Dak. 530.
Turkeys—
breeding, feed requirements, Mont. 677.
breeding stock, cost of wintering, N.Dak. 530.
fattening, Mont. 677.
feed consumption and growth standards, N.J. 532.
feeding, Ind. 820.
finishing, protein requirements, Nebr. 394.
growing, calcium utilization, Nebr. 239.
growing, feed costs, N.Dak. 530.
growth and feed consumpton, effect of season, 827.
management on small farms, U.S.D.A. 86.
protein, mineral, and vitamin requirements, Mont. 677.
rape v. alfalfa pasture for, N.Dak. 530.
rations for, [Conn.]Storrs 243.
roost dents in breast bones, Wyo. 89.
white corn and milk in rations, S.Dak. 677.
Turning sickness, relation to African coast fever, 693.
Turnip—
aphid, studies, Tex. 78.
greens, iodine in, Okla. 131.
mosaic transmitted by aphids, 58.
Turnips—
kerosene and petroleum oils in, distribution, 62.
magnesium requirements, Va.Truck 779.
susceptibility to *Rhizoctonia solani*, 61.
Twins—
developmental autonomy of skin and hair follicle, 469.
parabiotic, as means of determining cellular individuality, 330.
production in horses, inheritance of tendency, 467.
two-egg, with like characteristics in cattle, 192.
uniovular, 766.
Typhlocyba pomaria, see Apple leafhopper, white.
Typhoid, avian—
in poultry, breeding for resistance, Iowa 102.
in turkeys, 101.
Typhus—
fever, endemic strain, isolated from brain of wild rat, 399.
fever, endemic, susceptibility of opossum to, 373.
group diseases, criteria for accurate classification, 693.
role of rat flea in transmission, 694.
Tyroglyphus sp., parasite of oriental fruit moth, 815.
Udder infections, Idaho 690.
Udders of cows, causes of growth and function, 99.
Ulophora tephrosiella, damage to seeds of devil's shoestring, 660.
Ultraviolet—
light and respiratory phenomena, 27.
light, effect on fermentation of yeast, 28.
light, reactions of plants to, 27, 181.
radiation, monochromatic, effect on micro-organisms in liquid suspensions, 455.
radiation, transmission and antirachitic activation of evaporated milk films by, 251.

Ultraviolet—Continued.
solar radiation intensities, factors affecting, 444.
Understocks, *see* Rootstocks.
Undulant fever, treatment with brucellin, Mich. 843.
United States Department of Agriculture—
appropriation act of 1937, editorial, 289.
bulletins, index, 575.

Violet, sterile species hybrid, relation between cell, nuclear, and chromosome dimensions, 323.
Virginia Station, notes, 432.
Viruses, filtrable, staining and microscopical demonstration, 253.
Vitameter, Hilger, use for measuring vitamin A potency, 587.
Vitamin A—
activity of butter, Ind. 831.
and carotene, 885.
and D intake by hen, relation to egg production, 242.
assay, standardization of biological method for, Iowa 130.

Vitamin A—Continued.
deficiency—
and tissue lipids of rats, 883
effect on male sex organs of rat, 469.
effect on salivary secretion, 727.
effect on thyroid gland of rat, 429.
in rats, changes in vaginal epithelium, 570.
in rats, relation to castration, 569.
in spite of adequate diet in congenital atresia of bile ducts and jaundice, 137.
in swine, cause of lameness and death, N.C. 531.
relation to fetal death, prolonged gestation, and difficult parturition in rats, 89.
deficient diet, hematopoietic tissues of rats on, Fla. 717.
determinations with Hilger vitameter, 587.
effect on proliferation of fibroblasts, 425.
elimination from livers of rats previously given massive doses of vitamin A concentrate, 885.
formation in butter, suppressing action of soybeans, Ind. 830.
in apple varieties, 281.
in apples, Richared, peel and flesh of, Wash. 136.
in canned pineapple juice, 726.
in canned salmon, 884.
in chili peppers, 136.
in eggs, effect of diet of hen, Iowa 86.
in food materials, effect of heated fats on, Iowa 130.
in grapes, Thompson seedless, and raisins, 281.
in Hawaiian octopus and opihi, Hawaii 415.
in Iceberg lettuce, green and bleached, 136.
in milk, stability during irradiation, Wis. 564.
in nutrition of cattle and pigs, 528.
in Philippine fruits and vegetables, 570.
potency of butterfat, relation to carotene, Tex. 98.
potency of carotene fed in butterfat and Wesson oil, Ind. 830.
potency of carotene in butterfat and cottonseed oil, 726.
requirements of chicks, Ohio 389.
requirements of laying hens, Idaho 676.
requirements of poultry, N.J. 680.
reserve of embryo and baby chicks, 681.
storage by chickens, 390.
Vitamin, antineuritic, *see* Vitamin B (B_1).
Vitamin B_1—
and thyroxine, 425.
cleavage with sulfite, 588.
crystalline, composition and ultraviolet absorption, 587.
crystalline, properties, 282.
Vitamin B_1—Continued.
deficiency, blood pyruvate in, 285.
deficiency, effect on gastric juice of man, 571.
deficient ration, effect on coccidian infection, 399.
in animal tissues, Wis. 564.
in baker's yeast, Wis. 564.
in canned pineapple juice, 726.
in figs, 282.
in grapes, Thompson seedless, and raisins, 281.
in Iceberg lettuce, green and bleached, 136.
in lamb organs, S.Dak. 728.
in meat, N.Dak. 564.
in organs of rats, 886.
in Philippine fruits and vegetables, 570.
in prunes, 282.
requirements, effect of high fat-containing diets, 426.
stability, Wis. 564.
Vitamin B_2, *see* Vitamin G.
Vitamin B_4 in *Aspergillus sydowi*, 566.
Vitamin B_6—
definition, 888.
studies, 283.
Vitamin B complex—
carrier irradiated with ultraviolet light, effect on antidermatitis factor, 727.
deficiency and thyroid gland, 469.
deficiency, effect on anemia and leukopenia of monkeys, 426.
deficiency, effect on redox system in eye lens, 284.
differentiation, survey of literature, 888.
in *Aspergillus* spp., 566.
irradiated, and dermatitis, Mo. 131.
skin lesions of rat associated with, Mo. 886.
three members of, Mo. 888.
Vitamin C—*see also* Ascorbic acid.
destruction, Wis. 564.
determination, enzymic method, 588.
effect on plant growth, 25.
in apple varieties, 281; Wash. 136.
in apples, relation to human welfare, 426.
in canned pineapple juice, 726.
in Chili peppers, 136.
in eye lens, relation to vitamin B_2, deficiency, 284.
in grapes, Thompson seedless, and raisins, 281.
in Iceberg lettuce, green and bleached, 136.
in liver, S.Dak. 728.
in milk, 729.
in milk, effect of ration, 245.
in oats, sprouted, 571.
in orange-flavored drinks, Mass. 563.
in organs of chicks raised on vitamin C-deficient ration, 729.
in organs of guinea pigs, effects of experimental diets, 729.

Vitamin C—Continued.
in potatoes, effect of storage, Wyo. 138.
in prunes, fresh, cold stored, and frozen, Idaho 726.
in raspberries when frozen and after thawing, Wash. 130.
in rhubarb, raw, cooked, and canned, Mass. 563.
in urine, determination, 741, 742, 744.
in vegetables, chlorophyll- and nonchlorophyll-containing, 416.
in *Vigna sinensis*, distribution, 456.
requirement of guinea pigs, 285.
research, marked progress in, N.Y.State 728.
review of literature, 571.
Vitamin D—
bio-assay of milk, 889.
containing material, separation of sterols from, 11.
estimation, 827.
in corn silage, Mich. 683.
in eggs, effect of diet of hen, Iowa 86.
in Iceberg lettuce, green and bleached, 136.
in irradiated milk, metabolized milk, and cod-liver oil, antirachitic efficiency, 246.
in milk, S.Dak. 245.
in milk, effect of breeding, S.Dak. 684.
in milk, effect of roughage, S.Dak. 684.
in salmon, canned, 884.
lack of in common foods, 426.
menhaden oils as source for poultry, Md. 392.
milk, differential antirachitic activity, 246.
requirement of calves, Mich. 683.
requirements of chicks when grown in absence of sunlight, Tex. 95.
requirements of lambs, Ohio 389.
sources, effect on growth of chicks, Mo. 86.
sources, effect on storage of antirachitic factor in fowls, 830.
studies, Mass. 564.
Vitamin E—
and gonads, 766.
deficiency, paresis due to, 285.
properties of oily alcohol from wheat-germ oil, 742.
relation to sterility in goats, Iowa 97.
Vitamin F, see Vitamin B (B_1).
Vitamin G—
and pellagra-like dermatitis of rats, 282.
complex, flavine and antipellagra fraction as separate constituents, 284.
complex in milk, effect of feed of cow, Ohio 395.
components of, 137.
concentration by adsorption and elution from fuller's earth, 6.
deficiency in rats, pathological skin changes in tail, 888.
deficient diet, relation to cataract in rats, 727, 886.
Vitamin G—Continued.
deficient diet, relation to dermatitis, 727.
deficient ration, effect on coccidian infection, 399.
for growing chicks, amount, Wash. 88.
in dried skim milk, effect of process of manufacture, 251.
in figs, 282.
in Iceberg lettuce, green and bleached, 136.
in lamb organs, S.Dak. 728.
in liver, separation of flavines from, Wis. 564
in meat, N.Dak. 564.
in pineapple juice, canned, 726.
in potatoes, Netted Gem, Idaho 726.
in prunes, 282.
multiple nature, modification of Sherman method of study, 569.
requirements of chicks, 95, Ohio 389.
sources and coccidian infection, 840.
survey of literature, 888.
value in foods, procedure for determining, Idaho 726.
Vitamin H, provisional term, Mo. 888.
Vitamins—
and growth factors in plants, 462.
deficiency—*see also* Avitaminosis *and specific vitamins*.
of each, diseases of animals resulting from, 238.
G. Grijns' researches on, 424.
in female sex hormone, 469.
in theory and practice, treatise, 425.
in winter diet of rural school children, 726.
multiple nature, modification of Sherman method of study, 569.
past and present knowledge, Minn. 735.
retained in sulfured and unsulfured dried fruits, 282.
Volutella pachysandrae blight on *Pachysandra* in New Jersey, U.S.D.A. 636.
Walnuts—
black, seedling production, 633.
infection by fungi, 369.
root system, 48.
Washington College, notes, 432.
Washington, George, and agriculture, U.S.D.A. 876.
Washington Station, notes, 143, 432.
Washington Station, report, 141.
Wasp, killer, causing paralysis of cicada, nerve lesions of, 879.
Water—
added to milk, detection, 744.
and sewage studies, N.J. 702.
bacteriological analysis, media for, Mass. 436.
bath, constant-temperature, inexpensive, U.S.D.A. 75.
control, effect on peat and muck soils, Fla. 591.
control facilities, development, Ohio 353.
determination in various products, 154.

Water—Continued.
distilled, free from carbon dioxide and ammonia, continuous production, 585.
drinking, iodine in, 507.
ground, in south-central Tennessee, 851.
heated, value for swine, Ind. 819.
heaters, electric, optimum temperature, Wash. 141.
heating for livestock, Nebr. 260.
heavy, effect on yeast growth, 456.
heavy, enzymic reactions in, 295.
ice, storage studies, 252.
irrigation and drainage, quality, Wash. 15
losses, control, cropping methods for, 471.
movement in soil under apple trees, N.Y.State 20.
potability, relation to fluorine content, 851.
promoting circulation, small inexpensive stirrer for, U.S.D.A. 76.
rain, *see* Rainwater.
resources of Kentucky, 270.
saline drinking, effect on pH of intestinal tract, nitrogen balance, and coefficient of digestibility, 237.
specific yield, determination, Thiem method, 549.
subsurface, composition, Fla. 591.
supplies, nitrifying bacteria in, 267.
supply equipment for farms, 267.
supply, limited, use for irrigating citrus orchards, 702.
supply of the United States, 111, 549, 851.
underground, law of, 702.
underground, papers on, 702.
use, preferential rights and authority for enforcement, 702.
vapor loss from freshly unfolded leaves, 183.
wax for prevention of shrivelling of fruits and vegetables, 628.
wheels and pumps for irrigation, Mont. 701.
Waterfowl—
management in Michigan, 373.
plants significant to, distribution and ecology, Iowa 24.
Watermelon—
anthracnose resistant variety, 495.
crosses with different seed coat colors, factor interaction, 323.
plants with *Fusarium* wilt, leaf temperature, Tex. 57.
wilt, control, Fla. 636.
wilt-resistant strains, breeding and selection, Iowa 55.
wilt-resistant varieties and strains, pathological relation of host and parasite, Iowa 364.
wilt-resistant varieties of Iowa, testing in Texas, Tex. 57.
wilt-resistant variety, Leesburg, for Florida, 647; Fla. 67.
wilt, seeds as carriers, 788; Tex. 57.
Watermelons—
culture experiments, Ga.Coastal Plain 197.
fertilizer experiments, Ga.Coastal Plain 197.
Hawaiian, composition, nutritive value, and use, Hawaii 879.
inheritance of characters, Iowa 44.
total soluble solids and sugars in, 343.
variety tests, Ga.Coastal Plain 197.
Verticillium affecting, U.S.D.A. 356.
Watersheds, denuded, safeguards on, 702.
Wax, embedding, use of petroleum ceresin in, 321.
Wax flower, culture, P.R. 778.
Wax moth—
life history and control, U.S.D.A. 520.
occurrence and biology, 82.
Wax scale, Florida, in Palestine, 818.
Weather—*see also* Meteorological observations *and* Meteorology.
and precipitation, effect of temperature variation in Denmark, 591.
and solar radiation studies, 161.
Bureau, report of Chief, U.S.D.A. 580, 590.
charts, synoptic, forecasting from, U.S.D.A. 305.
conditions, cumulative effect on pastures, Ohio 331.
effect of solar variability, 746.
forecasting, value of particular period, simple test, 12.
relation to crops, Kans. 12.
Weathering and soil formation, 447.
Webworm, fall, feeding and utilization of sucrose solutions by, 659.
Webworms, sod, control in turf, Iowa 77.
Weed seeds—
coat structure and factors affecting germination, Iowa 35.
thermal death point, 482.
Weeds—
control, 625; Nebr. 195; Tex. 38.
control in California, 482.
control in growing corn, Iowa 111.
identification and control, Mont. 637.
life histories, N.Dak. 475.
sodium chlorate-limestone mixture for killing, Ohio 331.
Weir measurements, secondary factors in, 260.
Wells—
drainage effect, Idaho 701.
irrigation, construction, N.Mex. 111.
pump, experimental verification of theories, 702.
West Virginia Station, notes, 432.
West Virginia University, notes, 432.
Wetting agents, new, in place of soap, N.J. 658.
Wheat—
and rye amphidiploid, chromosome differences in, 190.
and wheat products, fatty constituents, relation to technical value of flour, N.Dak. 436.

Wheat—Continued.
as pasture crop, Ohio 395.
as substitute for bran and middlings in broiler rations, Ind. 819.
Belt, hard red winter, regional land use for, 476.
black chaff disease, 211, 500.
bran, feeding value, Kans. 531.
breeding, Idaho 616; Iowa 35; Mont. 616; N.Dak. 474; Nebr. 195.
bunt, *see* Wheat smut, stinking.
changes in carbohydrate content during hardening process for drought resistance, 760.
crosses, inheritance of resistance to hessian fly, 670.
crown and root development in, 479.
culm characters and hessian fly infestation, 775.
culture, effect of nitrogen, seeding rate, and climate, 175.
culture experiments, Ga.Coastal Plain 194.
development stages in, 314.
diseases, studies, Ind. 789; Mont. 637.
durum, color of, N.Dak. 475.
effects of vernalization, 185.
feeding to finishing yearling steers, Mont. 676.
feeding value, Colo. 531.
fertilizer experiments, Alaska Col. 766; Idaho 616; Tex. 38; Wash. 38.
flour, *see* flour.
from selenized soil, toxicity to rats, inhibiting effect of sulfur, 842.
futures on Chicago Board of Trade, open commitments in, analysis, U.S.D.A. 558.
gasoline extract, nature of pigments, Minn. 583.
germ oil, isolation of α-tocopherol from, 742.
germ preparation, effect on retention of mineral elements during pregnancy, 724.
gray shorts for prevention of slipped tendons in battery brooder chicks, Tex. 682.
head blight and root rot, Tenn. 789.
hybrids, cytology, 762.
hybrids differing in rust reactions, chemical analyses, 359.
improvement in Kansas, 36.
improvement in southwestern Indiana, Ind. 707.
inheritance, reaction to bunt biotypes, spike density, and seed color, Wash. 30.
inheritance studies, Wash. 38.
inoculation with loose smuts, method, 630.
insect pest survey, biology and control, Iowa 77.
Japanese self-sufficiency in, 274.
kernel, development, effect of awn, 479.
Wheat—Continued.
leaf rust—
effect on yield, composition, and quality, Ind. 789.
invasion and infection, relation to stomatal function, 792.
reaction of genus *Hordeum* to, 641.
relation to rate of transpiration, 494.
loose smut, inoculation method, 495.
meal, dilute alcohol or acetone extract, pigments of, Minn. 583.
meal fermentation time test for measuring quality, Ind. 776.
meal fermentation time test for varieties, N.Dak. 475.
meal, granulation test, research on, Ind. 767.
Michigan Wonder and Fulcaster, improved strains, Mo. 36.
milling and baking tests, U.S.D.A. 196.
new, selecting, value of viscosity tests, Ohio 331.
outlook charts, U.S.D.A. 120.
photosynthesis, light intensity and carbon dioxide concentration as factors, 181.
physiology, relation to rust resistance, 358.
plants, salt nutrition, effect on indicators of condition, 186.
prices and acreage in Great Britain, 275.
prices, relation to quality, Tex. 120.
prices, seasonal and short-time fluctuations in, Kans. 274.
protein determination, selenium catalyst in, 9.
quality, effect of combine harvesting, N.Dak. 475.
red and white, distribution in Michigan, Mich. 893.
resistance to winter-killing, causes reducing, 338.
response to phosphorus, Mont. 616.
root characteristics, relation to winter injury, Ohio 331.
root rot, studies, 59.
roots, characteristics, relation to winter injury, Ohio 624.
rotation experiments, Ind. 767.
rust—*see also* Cereal rusts, Rusts, *and* Wheat leaf and stem rust.
resistance, nature, 358.
resistant, breeding, 359.
seed and milling, survey, Ohio 196.
seed-borne diseases, dust fungicides for, tests, Iowa 55.
seed, examination to determine disease factor, 359.
seed, germination, effect of sulfur waters, 317.
seed, State certified, N.J. 339.
seedling, morphology, factors affecting, 479.
shriveled light weight, use, N.Dak. 43.
situation, Okla. 709.

Wheat—Continued.
situation, world, 274.
smut—*see also* Cereal smuts *and* Grain smuts.
resistance or immunity, breeding for, Mo. 36.
smut, stinking—
control, 499.
degrees of resistance recognizable in F_2 plants, 641.
in hybrids of Turkey type, inheritance of resistance to, Calif. 59.
seed treatment for, Idaho 637; Wyo. 58.
smut, studies, Wash. 58.
smut, survey of southeastern Idaho, Idaho 637.
smuts, N.Dak. 497.
spring—
breeding, S.Dak. 617.
Canadian hard red, varietal composition, 776.
combine investigations, Minn. 618.
culture experiments, Wyo. 39.
hard red, protein in, N.Dak. 436.
plat and nursery experiments, U.S.D.A. 195.
variety tests, Idaho 616; Wash. 38; Wyo. 39.
yields, Ind. 767.
spring-sown, variety tests, N.Mex. 36.
starch gels, effect of freezing on physical and microscopic character, 277.
stem rust—
epidemic of 1935 in Kansas, U.S.D.A. 793.
epiphytotic in South Dakota, U.S.D.A. 207.
in Hope variety, effect of light intensity and temperature, 211.
resistance, relation to nitrogen in mature and immature tissues, 211.
stripe rust, studies, 500.
studies of Food Research Institute, 274.
susceptibility to *Rhizoctonia solani*, 61.
take-all, effect on roots, crowns, and culms, 494.
testing for smut dockage and protein content, Mont. 616.
Thatcher, characteristics, Minn. 480.
top dressing with soluble nitrogen in April, Ind. 767.
types, starch from, physical and chemical properties, N.Dak. 436.
varieties from different localities, blending, N.Dak. 475.
variety tests, Alaska Col. 766; Ga. Coastal Plain, 194; Iowa 35; Mo. 36; N.Dak. 474; N.J. 616; N.Mex. 36; Nebr. 195; Ohio 331; S.C. 37; Tenn. 767; Tex. 38; Utah 234.
variety-cultural experiments, Iowa 35.
vitreous kernels in, effect of nutrition, Ind. 767.
Wheat—Continued.
winter—
and soil moisture with suggestions on abandonment, Kans. 338.
breeding, S.Dak. 617.
Canawa, a new variety of soft red, W.Va. 755.
culture experiments, Wyo. 39.
quality, effect of climate, soil, and fertilizers, Ohio 480.
varieties, acre yields, Ind. 767.
varieties, carotenoid pigments in, Ind. 767.
variety tests, Idaho 616; Wash. 38; Wyo. 39.
winter-sown, variety tests, N.Mex. 36.
wireworm, morphology and biology, Me. 817.
wireworm, vector of Stewart's disease, Mich. 642.
yield and chinch bug abundance, Ohio 374.
yield, effect of legumes and fertilizers, Ind. 767.
yield in Italy, effect of spring rains, 12.
yield on heavy soils, nitrogen top dressing experiments, Mich. 196.
Wheatgrass—
bluebunch, nutritive value, Wash. 88.
breeding, Idaho 616.
crested, germination, 626.
crested, introduction, testing, and distribution, Mont. 616.
crested, seed production studies, Wash. 38.
Wheels, loaded spoked, analysis, formulas, and use, U.S.D.A. 552.
Whey—
Babcock testing and other methods of analyzing, Nebr. 687.
need of large quantities for gilts, Wis. 530.
White ants, *see* Termites.
White grubs—
control in lawns, Ohio 374.
injury to seedling apple and pear trees, Conn.[New Haven] 657.
studies, Iowa 77; Wis. 518.
White pine blister rust—
control, Conn.[New Haven] 356; Ohio 53, 357.
different spore stages, dates of production, 223.
first found in California, U.S.D.A. 789.
on sugar pine, first record, U.S.D.A. 635.
sporidia, production and germination, 508.
White pine—
reproduction, N.H. 493.
seed, stratification to speed germination of spring-sown seed, Mich. 785.
stumpage returns, effect of repeated ground fires, 786.
Whiteflies, control with lime-sulfur, Fla. 658.
Whitefly, citrus, effect of freeze of 1934, 662.

Whiting, Atlantic, studies, Mass. 563.
Wildlife—
cycles, effect of sun, Wis. 509.
forest, census methods applicable to New England conditions, 804.
in United States, planning for, 803.
research, cooperative, 143.
Willow—
golden, *Phyllosticta apicalis* on, 789.
insects affecting, biology and control, 807.
pussy, stem and twig blight, Tex. 57.
Wind—
curbing, 36.
erosion, cultural methods of control, 476.
farm building losses due to, Iowa 111.
velocities, effect on growth and transpiration in plants, 182.
Windbreaks, *see* Trees, windbreak.
Winds above Caribbean Sea, collecting micro-organisms from, 495.
Wine—
analysis, methods, 304.
mellowing and stabilization, 589.
use and dietary values, 880.
Winter fat, growth and germination, N.Mex. 37.
Winter moth, biology and control, 380.
Wireworm—
eggs, counting, methods, U.S.D.A. 77.
flat, in Canada, 817.
Gulf, life history, habits, and distribution, 528.
plains false, studies, Tex. 78.
Wireworms—
control, paradichlorobenzene for, N.J. 658.
in Maine, bionomics and control, Me. 817.
in tobacco fields of Yamaska Valley, survey, 806.
increase in red clover or sweetclover fields, Idaho 658.
temperature and moisture preferences, 384.
Wisconsin Station, notes, 736.
Wisconsin Station, report, 575.
Wohlfahrtia vigil, laboratory breeding, 806.
Women—
associated country, of world, triennial conference, editorial, 145.
college, growth in height and weight, 420.
college, of Wyoming, basal metabolism, 721.
farm energy requirement, 721.
married, on full-time outside occupations, housekeeping activities in home, R.I. 892.
Wood—*see also* Lumber *and* Timber.
extractive substances, effect on durability of paint coatings, U.S.D.A. 114.
fire-retardant door, one hour fire test, 705.
lot management, Ind. 784.
Wood—Continued.
movement of liquids in, Minn. 601.
ring v. scattered pores in, physiological significance, 184.
rotting fungus, variations in morphology and growth habit, 654.
shrinkage and swelling, minimizing, 855.
surfaces, repainting, exposure test, 262.
untreated, decay and resistance of different species, U.S.D.A. 114.
using trades, Government publications of interest to, U.S.D.A. 703.
Woody plants—
damping-off and growth of seedlings and cuttings, Mass. 496.
establishing for erosion control, Iowa 111.
mushroom root rot of, Fla. 637.
starch and fat reserves in, seasonal changes, 24.
translocation of nitrogen in, 344.
Wool—
alkaline mercerization, 139.
and mohair, Texas, grades and shrinkages, Tex. 88.
characters in sheep crosses, 762.
characters in sheep, inheritance, 762.
chlorinated, acid and alkaline degradation, 585.
classification, grades and uses, U.S.D.A. 286.
fabric, chlorinated, resistance to acid and to alkaline solutions, Iowa 139.
fabrics, judging, Minn. 734.
fat, distribution over fleece of Merino sheep, 240.
fineness, relation to age of animal, Tex. 88.
improvement, cross-breeding and selection for, Mich. 676.
inheritability, N.Dak. 580.
keratin, acid degradation, 584.
kinds, effect on physical properties of flannel, S.Dak. 734.
merino, milling properties, effect of fiber length, 890.
outlook charts, U.S.D.A. 120.
photochemical oxidation, 890.
production, effect of pregnancy and early lactation, 528.
production, inheritance, 324.
shrinkage studies, Wyo. 139.
tip on fine fleeces, relation to top-making qualities, 528.
world consumption and trade, 559.
Woolly aphid, *see* Apple aphid, woolly.
Worms—
of sheep and goats in India, control, 104.
parasitic, recent developments in study, 373.
transparent specimens, preparation, 321.
Wormseed oil production, Md. 204.
Wounds—
healing with blowfly maggots, 105.
myiases of, 816.

Wounds—Continued.
of domestic animals, prevention of myiasis in with bone oil, 539.
Wyoming Station, report, 141.
X disease, Australian, 692.
Xenopsylla cheopis, see Rat flea, oriental.
X-rayed male mice, effect on progeny, 468.
X-rays—
effect on electrophoretic mobility of *Escherichia coli*, 605.
effect on glutathione, 149.
effect on sex gland and secondary sexual characters in *Lebistes reticulatus*, 469.
irradiation of male mice, effects, 470.
modification of leaf structure by, 184.
Xylan from corncobs, Iowa 4.
Xylene for eradication of root rot, tests, Tex. 57.
Xylocoris cursitans, predator of *Tribolium*, 524.
Yams—
for Hawaiian gardens, Hawaii. Sugar Planters' 776.
transmission from man to rabbits by an insect vector, 816.
Yeast—
added to basal ration, effect on growth rate and slipped tendon in chicks, 828.
anaerobic fermentation, influence of various regions of spectrum, 28.
baker's, growth and vitamin B_1 in, factors affecting, Wis. 564.
causing gas in sweetened condensed milk, 251.
essential dietary factor in, distinct from vitamins B_1, B_2, and B_6 and flavines, 889.
making process, methods of improving, Wis. 442.
milk, antirachitic efficiency, Ohio 395.
S and R forms, fermentation products, 320.
Young Men's Conference "On Behalf of a Continent", editorial, 577.
Young people—
married, activities, interests, and problems of, [N.Y.]Cornell 561.
occupation and earnings, Wis. 560.
Young people—Continued.
rural, face their own situation, 716.
rural, rate of departure from parental home, 715.
Youngberry anther and stigma blight in Oregon, U.S.D.A. 789.
Ypsolophus marginellus, control, 668.
Yucca as forage crop, Wyo. 89.
Zein—
utilization by rats, 280.
white, preparation from yellow corn, Minn. 582.
Zeuzera pyrina, see Leopard moth.
Zinc—
chloride, activity of coefficient, effect of amino acids, 294.
coatings on steel, corrosion-protective value, 115.
cobaltinitrite for detection of potassium, 155.
deficiency disease of beans, Fla. 637.
deficiency, relation to pecan rosette, 507.
in soils, behavior, Fla. 591.
indispensability in nutrition of rat, 424.
pellets for generation of arsine in Gutzeit method, 296.
requirements in animal nutrition, Wis. 530.
response of corn to, Fla. 615.
role in peat and muck soils of Everglades, Fla. 591.
spectrographic microdetermination, 441.
sulfate, addition to pituitary synergist, effect, 328.
sulfate, effect on corn, Fla. 636.
sulfate in fruit sprays, effect, Ill. 801.
sulfate in soil, behavior and toxicity, 603.
sulfate, relation to injury from peach and apple sprays, 494.
sulfate studies, progress in, 210.
sulfate, use under corn and other crops, Fla. 209.
Zizyphus spp., insect pests of, 800.
Zoology, economic, history in Philippines, 375.
Zophodia grossulariae, see Gooseberry fruitworm.
